RE: Redesignation of Kentucky portion of the Cincinnati-Hamilton OH-KY-IN fine particulate nonattainment area

Dear Ms. Fleming:

Enclosed for your consideration is the final revision to Kentucky's State Implementation Plan to redesignate the Kentucky portion of the Cincinnati-Hamilton OH-KY-IN $PM_{2.5}$ nonattainment area (Boone, Campbell, and Kenton counties) as attainment for the $PM_{2.5}$ National Ambient Air Quality Standard.

A public hearing to receive comments on this revision was held December 15, 2010, at 6:00 p.m. in the Conference Room of the Northern Kentucky Area Development District (NKADD), 22 Spiral Drive, Florence, Kentucky. A copy of the public hearing notice and the statement of consideration are included in this submittal.

Ohio and Indiana are making separate redesignation requests for their respective portions of the metropolitan area and have submitted those demonstrations to U.S. EPA, Region 5.

Your prompt consideration of this request is appreciated. If you have any questions or comments concerning this matter, please contact Andrea Smith with the Division for Air Quality at (502) 564-3999.

Sincerely Yours,

Leonard K. Peters
Secretary

I - Notice of Public Hearing & Statement of Consideration

INTRODUCTION

The Cincinnati-Hamilton area is designated as a fine particulate ($PM_{2.5}$) Nonattainment Area for the annual standard of the 1997 National Ambient Air Quality Standard (NAAQS) of 15.0 micrograms per cubic centimeter (ug/m^3) for $PM_{2.5}$. This document is intended to support Kentucky's request that the Kentucky portions of the Cincinnati-Hamilton area be redesignated from nonattainment to attainment for the annual standard. In addition, the States of Ohio and Indiana also intend to submit requests for their respective portions of the Cincinnati-Hamilton area. Copies of the Ohio and Indiana submittal can be found in *Appendix H*.

In accordance with section 110(k) of the Clean Air Act Amendments of 1990, Kentucky's request to amend the State Implementation Plan (SIP) is based on the most recent three (3) years of monitoring data showing no additional violations of the annual standard for the 2007-2009 time period, and a calculated $PM_{2.5}$ design value for 2007-2009 data that is attaining the NAAQS. This submittal does not address attainment or designation issues regarding the 24-hour standard. Permanent and enforceable reductions in fine particulate emissions have occurred and emission projections demonstrate that the 2008 attainment year emission levels in this area will not be exceeded during the next 10 years.

This redesignation request was prepared in accordance with the U.S. EPA memorandum from John Calcagni, June 23, 1992, "Subject: Processing of SIP Submittals," and the U.S. EPA memorandum from John Calcagni, September 4, 1992, "Subject: Procedures for Processing Requests to Redesignate Areas to Attainment," and the U.S. EPA memorandum from William Harnett, October 2, 2007, "Subject: Guidance on SIP Elements Required Under Sections

110(a)(1) and (2) for the 1997 8-hour Ozone and $PM_{2.5}$ National Ambient Air Quality Standards" (*Appendix A).*

BACKGROUND

The Clean Air Act Amendments of 1990 (CAA) establishes a process for air quality management through the NAAQS. Area designations are required after promulgation of a new or revised NAAQS. On July 18, 1997, the U.S. EPA revised the NAAQS particulate standard to add new standards for $PM_{2.5}$, using $PM_{2.5}$ as the indicator pollutant. The U.S. EPA established health-based (primary) annual and 24-hour standards for $PM_{2.5}$ (*Appendix B*, 62 FR 38652*).* The welfare-based (secondary) standards for both were established as identical to the primary standard. Secondary standards are designed to protect against major environmental effects of $PM_{2.5}$ such as visibility impairment, soiling, and materials damage.

The annual standard is a level of 15 micrograms per cubic meter (ug/m^3), based on the 3-year average of the annual mean $PM_{2.5}$ concentrations. The U.S. EPA established the standard based on evidence from numerous health studies demonstrating that serious health effects are associated with exposures to elevated levels of $PM_{2.5}$. The U.S. EPA and State air quality agencies initiated the monitoring process for the $PM_{2.5}$ NAAQS in 1999, and deployed all air quality monitors by January 2001.

Airborne particles generally less than or equal to 2.5 micrometers in diameter are considered to be "fine particles". "Primary" particles are emitted directly into the air as a solid or liquid particle (e.g. elemental carbon from diesel engines or fire activities, or condensable organic

particles from gasoline engines). "Secondary" particles (e.g. sulfate and nitrate) form in the atmosphere as a result of various chemical reactions. Five main types of pollutants contribute to fine particle concentrations: direct $PM_{2.5}$ emissions; sulfur dioxide (SO_2); nitrogen oxides (NO_x); ammonia (NH_3); and volatile organic compounds (VOCs).

However, the effect of reducing emissions of each of these pollutants varies area by area, depending on the fine particle composition, emission levels, and other area-specific elements. Kentucky's main $PM_{2.5}$ components are primary particles, SO_2, and NO_x, which were included in the attainment demonstration analysis. Volatile organic compounds and ammonia were not included in the analysis since they were not part of Kentucky's current attainment strategy for $PM_{2.5}$. Note however that VOC controls have been implemented in northern Kentucky for ozone attainment as described in the SIP for resignation to attainment (*Appendix B*, 75 FR 47218).

The final rule for implementation published April 25, 2007, established policy for evaluating and controlling sources of these emissions (*Appendix B*, 72 FR 20586). $PM_{2.5}$, SO_2, and NO_x must be evaluated for emission reduction measures in all nonattainment areas. VOCs and NH_3 are not required to be evaluated for emission reduction measures in each area unless the state or the U.S. EPA demonstrates that these pollutants significantly contribute to $PM_{2.5}$ concentrations in a specific area.

The $PM_{2.5}$ NAAQS were challenged by numerous litigants and in May 1999, the U.S. Court of Appeals for the D.C. Circuit issued a decision remanding, but not vacating, the standards. In *American Trucking Association v. the U.S. EPA*, 175 F.3d 1027, 1047-48, on rehearing 195 F.3d

4 (D.C. Circuit, 1999), the U.S. EPA sought review of two aspects of that decision in the U.S. Supreme Court. The Supreme Court upheld the $PM_{2.5}$ standards in the *U.S. EPA v. American Trucking Association*, 531 U.S. 457 (S. Ct., 2001).

In March 2002, the D.C. Circuit Court rejected all remaining challenges to the $PM_{2.5}$ standards in *American Trucking Association v. the U.S. EPA*, 283 F.3d 355 (D.C. Circuit, 2002). Since final resolution of the litigation over the $PM_{2.5}$ NAAQS, the U.S. EPA has been acting to implement the standards.

The process for designating areas following promulgation of a new or revised NAAQS is contained in section 107(d)(1) of the CAA. The Transportation Equity Act for the 21st Century (TEA-21) extended the time for the U.S. EPA to initiate the designations process for the $PM_{2.5}$ NAAQS until three (3) calendar years of air quality data, measured at Federal Reference Method monitors, were gathered.

In April 2003, the U.S. EPA issued designation guidance concerning how to determine the boundaries for $PM_{2.5}$ nonattainment areas. The guidance provided that the U.S. EPA would use the three (3) most recent calendar years of monitoring data for $PM_{2.5}$ to determine each county's designation. The 2003 guidance memorandum described nine (9) factors that the U. S. EPA would consider in determining appropriate nonattainment area boundaries: (1) emissions and air quality in adjacent areas; (2) air quality in potentially included versus excluded areas; (3) population density and degree of urbanization including commercial development in included versus excluded areas; (4) traffic and commuting patterns; (5) expected growth (including extent,

pattern, and rate of growth); (6) meteorology (weather/transport patterns); (7) geography/topography (e.g. mountain ranges or other air basin boundaries); (8) jurisdictional boundaries (e.g. counties, air districts, reservations, etc.); and (9) level of existing controls on emission sources.

The U.S. EPA issued final designations for areas violating the 1997 standard on December 17, 2004. Designations were published (*Appendix B*, 70 FR 944) on January 5, 2005. On April 5, 2005 the U.S. EPA issued a supplemental notice which changed the designation status of eight (8) areas from nonattainment to attainment based on newly updated 2002-2004 air data.

Thus designations were finalized in the FR published January 5, 2005 and designation modifications were finalized (*Appendix B*, 70 FR 19844) and published April 14, 2005. The effective date for all designations was April 5, 2005.

In accordance with Section 107(d)(1) of the CAA, the U.S. EPA designated the Cincinnati-Hamilton area to be nonattainment for the annual $PM_{2.5}$ NAAQS. The current nonattainment area is located in northern Kentucky and includes the following counties: Boone, Campbell, and Kenton in Kentucky; Butler, Clermont, Hamilton, and Warren in Ohio; and Dearborn (partial nonattainment of Lawrenceburg Township only) in Indiana.

The nonattainment designation for an area starts the process whereby a State must develop an implementation plan that includes, among other things, an attainment demonstration showing how it will attain the ambient standards by the attainment dates required under the CAA. Under

section 172(b) of the CAA, States have up to three (3) years after the U.S. EPA's final designations to submit their SIPs to the U.S. EPA.

Section 172(a)(2) of the CAA requires States to attain the standard as expeditiously as practicable, but within five (5) years of designation. The U.S. EPA Administrator can extend an area's attainment date 1-5 years based on the severity of the nonattainment problem or the feasibility of implementing control measures.

Kentucky submitted an attainment demonstration for the Kentucky portion of the annual $PM_{2.5}$ nonattainment area in November 2008, using numbers modeled by the Visibility Improvement State and Tribal Association of the Southeast and the Association of Southeastern Integrated Planning (VISTAS/ASIP). That submittal provided documentation that each state in the nonattainment area would attain the annual $PM_{2.5}$ standard by April 5, 2010.

Ohio and Indiana also submitted attainment demonstrations for their $PM_{2.5}$ nonattainment portions; both States' SIP submittals relied on modeling provided by the Lake Michigan Air Director's Consortium (LADCO).

To date, no action has been taken by the U.S. EPA on those attainment demonstration submittals, primarily due to the uncertainty at that time over the Clean Air Interstate Rule (CAIR), the credit for emission reductions granted under that program, and the status of any future CAIR replacement rule.

The "Clean Air Fine Particle Implementation Rule" (*Appendix B*, 72 FR 20586) was issued March 10, 2005 to address the interstate transport of SO_2 and NO_x oxide emissions primarily from power plants. CAIR replaced the NO_x SIP Call for electric-generating units (EGUs). On October 4, 2007 the U.S. EPA published approval of a revision (*Appendix B*, 72 FR 56623) to Kentucky's SIP addressing CAIR requirements and a determination that the SIP fully implements the CAIR requirements for Kentucky.

The U.S. Court of Appeals for the D.C. Circuit has ruled on petitions for review of the CAIR and CAIR Federal Implementation Plans (FIPs), including their provisions establishing the CAIR NO_X annual and ozone season and SO_2 trading programs. On July 11, 2008, the Court issued an opinion (*North Carolina v. the U.S. EPA,* 531 F.3d 896, 901, D.C. Circuit 2008) vacating and remanding these rules; however, parties to the litigation requested rehearing of aspects of the Court's decision, including the vacatur of the rules. On December 23, 2008, the Court granted rehearing only to the extent that it remanded the rules to the U.S. EPA without vacating them (*North Carolina v. the U.S. EPA,* 531 F.3d 896, 905, D.C. Circuit 2008).

The December 23, 2008 court ruling left CAIR and the CAIR FIPs, including the CAIR trading programs, in place until the U.S. EPA issued a new rule to replace CAIR in accordance with the July 11, 2008 decision.

Upon the U.S. EPA designating in 2005, the Cincinnati-Hamilton area nonattainment for the 15 ug/m^3 annual standard, Kentucky was required to develop a plan to reduce NO_x, SO_x, and direct $PM_{2.5}$ emissions and to demonstrate that the area will meet the federal annual air quality standard by April 5, 2010. Kentucky's main $PM_{2.5}$ components are primary particles, SO_2, and NO_x,

which were included in the attainment demonstration analysis. As mentioned previously, VOCs and NH_3 were not included in the analysis since they were not part of Kentucky's current attainment strategy for $PM_{2.5}$. Kentucky emphasizes again that significant VOC reductions resulted from the VOCs controls that have been implemented for ozone attainment (*Appendix B*, 75 FR 47218, published August 5, 2010).

This is consistent with the U.S. EPA's "Clean Air Particle Implementation Rule" (*Appendix B*, 72 FR 20586, published April 25, 2007). In this rule, the U.S. EPA presumes NH_3 emissions are not a $PM_{2.5}$ attainment plan precursor and that States are not required to address VOC unless the State or the U.S. EPA makes technical demonstration that emissions of VOCs significantly contribute to nonattainment.

As noted previously, Kentucky developed regulations 401 KAR 51:210, 401 KAR 51:220, and 401 KAR 51:230 (effective February 2, 2007) in response to CAIR; those regulations are still in place. However, reductions due to this regulation and CAIR were not included in the inventory and its projections for the Kentucky portion of the nonattainment area.

On July 6th, 2010, the U.S. EPA issued the proposed Reduce Interstate Transport of Fine Particulate Matter and Ozone Rule (Transport Rule) to replace CAIR (*Appendix* B, 75 FR 45210). Specifically, this proposal would require significant reductions in SO_2 and NO_X that cross state lines. Emission reductions will begin to take effect in 2012, within one year after the rule is finalized. By 2014, the rule and other state and U.S. EPA actions would reduce SO_2 power plant emissions by 71% and NO_x emissions by 52% over 2005 levels.

Link to Transport Rule: **http://www.gpo.gov/fdsys/pkg/FR-2010-08-02/pdf/2010-17007.pdf#page=1**

Nonattainment problems are primarily a combination of local emissions and transported emissions from upwind sites. The structure of the CAA requires the U.S. EPA to develop national rules for certain types of sources which are significant contributors to local air quality problems, including motor vehicles and fuels. The CAA also provides for States to address emission sources on an area-specific basis through requirements as Reasonably Available Control Technology (RACT), Reasonably Available Control Measures (RACM), and Reasonable Further Progress (RFP). These national and state measures are included in a later discussion regarding emission controls applied.

Section 107(d)(3)(E) of the CAA allows states to request nonattainment areas to be redesignated to attainment provided certain criteria are met. The following are the criteria that must be met in order for an area to be redesignated from nonattainment to attainment:

- A determination that the area has attained the $PM_{2.5}$ standard.
- An approved SIP for the area under Section 110(k) of the CAA.
- A determination that the improvement in air quality is due to permanent and enforceable reductions in emissions resulting from implementation of the SIP and other federal requirements.
- A fully approved maintenance plan under Section 175(A) of the CAA.
- A determination that all Section 110 and Part D requirements have been met.

This document addresses each of these requirements to support Kentucky's request that the Kentucky portions of the Cincinnati-Hamilton area be redesignated from nonattainment to attainment for the annual $PM_{2.5}$ standard, and provides additional information to support continued compliance with the annual $PM_{2.5}$ standard. In addition, the States of Ohio and Indiana also intend to submit requests for their respective portions of the nonattainment area.

Complete $PM_{2.5}$ quality-assured and certified ambient air quality monitoring data for the most recent 3 years (2007-2009) demonstrates that the air quality has met the NAAQS for annual $PM_{2.5}$ in this nonattainment area. The NAAQS design value (Table 2), accompanied by decreases in emission levels shown in this document (Table 49), supports a redesignation to attainment for the Cincinnati-Hamilton area based on the requirements in Section 107(d)(3)(E) of the CAA.

IMPROVEMENT IN AIR QUALITY

The $PM_{2.5}$ annual nonattainment designation was based on air quality data collected from 2001 through 2003 that exceeded the specified NAAQS level of 15 ug/m^3. Because the designation process occurred so close to the end of 2004, complete, certified 2004 ambient monitoring data quality-assured and submitted by February 22, 2005, was considered as well (*Appendix B,* 72 FR 20586). Designations became effective April 5, 2005.

The $PM_{2.5}$ annual data for the nonattainment area indicated no further exceedances of the annual $PM_{2.5}$ NAAQS standard and resulted in a decline in the design value for the most recent 3-year period (2007-2009). The AQS ambient data report is included in *Appendix C*.

Table 1 is a summary of the annual mean concentrations for the annual $PM_{2.5}$ NAAQS for the counties in the nonattainment area and the 3-year averages (*Data Source: the U.S. EPA Air Quality System*). A map indicating the location of the Kentucky and Ohio $PM_{2.5}$ monitors in the Cincinnati-Hamilton nonattainment area is included in *Appendix C*. Boone County, Kentucky and Dearborn County, Indiana do not have a $PM_{2.5}$ monitoring station in the nonattainment area. The annual mean values in Table 1 demonstrate an overall downward trend across the entire nonattainment area.

Data Source: U.S. EPA AQS n/a – No data collected.

According to guidance provided in the U.S. EPA's "Guideline on Data Handling Conventions for the PM NAAQS," the U.S. EPA-454/R-99-008, April 1999, an area is in compliance with the annual $PM_{2.5}$ NAAQS only if every monitoring site in the area meets the NAAQS. An individual site's 3-year average of the annual average concentrations is also called the site's design value.

In Table 2, the current 3-year average (2007-2009) for each individual site shows the site design value in attainment, as each monitor has achieved a calculated NAAQS monitor value below the 15.0 ug/m^3. The air quality design value for the area is the highest design value among all sites in the area. The area design values calculated for Cincinnati-Hamilton demonstrate that the annual $PM_{2.5}$ NAAQS has been attained. The area's design values have trended downward as

emissions have declined due to factors such as cleaner engine designs and fuels, and controls for EGUs. Emissions reductions are discussed in the section to follow.

The data collected by Kentucky was quality assured in accordance with 40 CFR 58 and was recorded in the U.S. EPA AQS and is therefore available to the public. The monitoring network will continue to remain operational in accordance to 40 CFR 58, with no monitoring reductions. The Air Quality System (AQS) ambient data report for $PM_{2.5}$ is included in *Appendix C.*

PERMANENT AND ENFORCEABLE EMISSION REDUCTIONS

The improvement in air quality in the Cincinnati-Hamilton area, as verified by the downward trend of fine particulate concentrations to a level attaining the annual NAAQS, is due to the implementation of permanent and enforceable emission reductions.

General meteorological information regarding temperatures and rainfall for years 2007 through 2009 are included in *Appendix C.*

On an annual basis, the monthly data indicates that 2007 overall in northern Kentucky was much warmer than normal, with numerous days June through September exceeding 90°F, while 2008 and 2009 were both less warm than normal. Precipitation on a monthly basis in 2007 was much drier than normal, with drought levels in the summer that would persist into the following year. However rainfall picked up by March, 2008, and overall 2008 was above normal for precipitation, while 2009 was closer to normal monthly rainfall levels. This information is

summarized as provided by the University of Kentucky Agricultural Weather Center at Covington in *Appendix C*.

Attaining the fine particulate NAAQS generally requires simultaneous emission reductions on the local, regional, and national levels. Emission reductions (in tons per day, or tpd) described below are from various programs and initiatives. The following categories of sources have shown or are expected to show emission reductions in direct $PM_{2.5}$, SO_2, and NO_x emissions due to regulatory measures implemented, both by the U.S. EPA and Kentucky.

CONTROLS APPLIED

Several control measures already in place or being implemented over the next few years will reduce stationary point, highway mobile, and nonroad mobile sources emissions. The Federal and State control measures were included for all of the future years and are discussed in the sections below.

FEDERAL CONTROL MEASURES

TIER 2 VEHICLE STANDARDS

On February 10, 2000, the U.S. EPA finalized a federal rule (65 FR 6698) to significantly reduce emissions from cars and light trucks, including sport utility vehicles (SUVs). Under this rule, automakers are required to sell cleaner cars, and refineries are required to make cleaner, low-sulfur gasoline. The federal rules were phased in between 2004 and 2009. The U.S. EPA has estimated that NO_x emission reductions will be approximately 77% for passenger cars, 86% for smaller SUVs, light trucks, and minivans; and 65% to 95% percent reductions for larger SUVs,

vans, and heavier trucks. Emission reductions of VOC will be approximately 12% for passenger cars; 18% for smaller SUVs, light trucks, and minivans; and 15% for larger SUVs, vans, and heavier trucks. The Tier 2 rule also reduced the sulfur content of gasoline to 30 parts per million (ppm) starting in January of 2006. Most gasoline sold in Kentucky prior to January 2006 had a sulfur content of approximately 300 ppm. Sulfur occurs naturally in gasoline, but interferes with the operation of catalytic converters on vehicles resulting in higher NOx emissions. Low-sulfur gasoline is necessary to achieve the Tier 2 vehicle emission standards.

HEAVY-DUTY GASOLINE AND DIESEL HIGHWAY VEHICLES STANDARDS

The U.S. EPA standards promulgated October 6, 2000, (65 FR 59896) to reduce NOx and VOC emissions from heavy-duty gasoline and diesel highway vehicles began to take effect in 2004. A second phase of standards and testing procedures, which began in 2007, began reducing particulate matter from heavy-duty highway engines, and reduces highway diesel fuel sulfur content to 15 ppm since the sulfur in fuel damages high efficiency catalytic exhaust emission control devices. The total program is expected to achieve a 90% reduction in particulate matter (PM) emissions and a 95% reduction in NOx emissions for these new engines using low-sulfur diesel, compared to existing engines using higher-content sulfur diesel.

LARGE NONROAD DIESEL ENGINES RULE

On May 11, 2004, the U.S. EPA promulgated new rules (69 FR 26222) for large nonroad diesel engines, such as those used in construction, agricultural, and industrial equipment, to be phased in between 2008 and 2014. The nonroad diesel rules also reduce the allowable sulfur in nonroad diesel fuel by over 99% by 2010. The U.S. EPA estimates that affected nonroad diesel engines

currently account for about 44% of total diesel PM emissions and about 12% of total NOx from mobile sources nationwide. These proportions can be even higher in some urban areas. Nonroad diesel fuel currently averages about 3,400 ppm sulfur. The rule has limited nonroad diesel sulfur content to 500 ppm in 2006 and 15 ppm in 2010. The combined engine and fuel rules would reduce NOx and PM emissions from large nonroad diesel engines by over 90%, compared to current nonroad engines using higher-content sulfur diesel.

NONROAD SPARK-IGNITION ENGINES AND RECREATIONAL ENGINES STANDARD

On November 8, 2002, the U.S. EPA promulgated rules (67 FR 68242) that regulate NOx, hydrocarbons (HC) and carbon monoxide (CO) for groups of previously unregulated nonroad engines. The standard applies to all new engines sold in the United States and imported after these standards began and applies to large spark-ignition engines (forklifts and airport ground service equipment), recreational vehicles (off-highway motorcycles and all-terrain-vehicles), and recreational marine diesel engines. The regulation varies based upon the type of engine or vehicle.

The large spark-ignition engines contribute to ozone formation and ambient CO and PM levels in urban areas. Tier 1 of this standard was implemented in 2004 while Tier 2 began in 2007. Like the large spark-ignition, recreational vehicles contribute to PM levels, as well ozone formation and ambient CO. For the off-highway motorcycles and all-terrain-vehicles, model year 2006, the new exhaust emissions standard was phased-in by 50% and for model years 2007 and later at 100%. Recreational marine diesel engines over 37 kilowatts are used in yachts, cruisers, and other types of pleasure craft. Recreational marine engines contribute to PM levels and ozone

formation, especially in marinas. Depending on the size of the engine, the standard began to be phased-in during 2006.

When all of the nonroad spark-ignition engines and recreational engines standards are fully implemented, an overall 72% reduction in HC, 80% reduction in NOx, and 56% reduction in CO emissions are expected by 2020. These controls will help reduce ambient concentrations of fine particulate matter, CO, and ozone.

NOx SIP Call in Surrounding States

On October 27, 1998, the U.S. EPA made a finding of significant contribution of NOx emissions from certain states and published a rule that set ozone season NOx budgets for the purpose of reducing regional transport of ozone (63 FR 57356). This rule, referred to as the NOx SIP Call, required ozone season controls to be put on utility and very large industrial boilers, as well as internal combustion engines in 22 states in the Eastern United States. This resulted in a NOx emissions budget for each state and the states were required to develop rules to meet their budget.

A trading program of NOx emissions was established, allowing sources to buy credits to meet their NOx budget as opposed to actually installing controls. The emission budgets were to be met by May of 2004. The amount of NOx emissions have decreased significantly in and around Kentucky. In fact, 2009 Kentucky emission inventory surveys indicate that NO_x emissions decreased by 2080 tons from the previous year.

STATE CONTROL MEASURES

Kentucky has adopted a number of regulations and legislation to address pollution issues across the State. These include the NOx SIP Call and the Open Burning Rules. These regulations are summarized below.

NOX SIP CALL RULE

In response to the U.S. EPA's NOx SIP call, Kentucky adopted rules to control the emissions of NOx from large stationary combustion sources. These rules cover fossil fuel-fired stationary boilers, combustion turbines, and combined cycle systems serving a generator with a nameplate capacity greater than 25 megawatts and selling any amount of electricity; fossil fuel-fired stationary boilers, combustion turbines, and combined cycle systems having a maximum design heat input greater than 250 million British thermal units per hour; and reciprocating stationary internal combustion engines rated at equal or greater than 2400 brake horsepower (3000 brake horsepower for diesel engines and 4400 brake horsepower for dual fuel engines). As part of the NOx SIP call, the U.S. EPA rules established a NOx budget for sources in Kentucky and other states.

Besides amending existing NOx rules and adopting new NOx rules specifically to address the U.S. EPA NOx SIP call, the Kentucky rules also require new sources to control emissions of NOx. The objective of this requirement is to aid in meeting the NOx budget for Kentucky for minor sources, and to aid in attaining and maintaining the ambient air quality standard for ozone in Kentucky. Kentucky's NOx SIP Call rule was predicted to reduce summertime NOx emissions from power plants and other industries statewide by 68% by 2006 (*Appendix G*).

KRS 224.10-100, *Powers and duties of the cabinet*, provides the Kentucky Energy and Environment Cabinet with the statutory authority to adopt and implement its NO_x SIP Call program. A link to KRS 224.10-100 is: **http://www.lrc.ky.gov/KRS/224-10/100.PDF**

REASONABLY AVAILABLE CONTROL MEASURES (RACM) - 401 KAR 50:012

The Kentucky $PM_{2.5}$ nonattainment areas will continue to implement the RACM measures already adopted. The analysis in the previously submitted "Kentucky Fine Particulate Matter ($PM_{2.5}$) Attainment Demonstration for the Louisville, KY-IN, Cincinnati-Middletown, OH-KY-IN, and Huntington-Ashland, WV-KY-OH $PM_{2.5}$ Nonattainment Areas" (December 2008) established that these measures contributed to the region being able to comply with the $PM_{2.5}$ NAAQS (1997).

A link to 401 KAR 50:012, *General application*, can be found at **http://www.lrc.state.ky.us/KAR/401/050/012.htm** and included in *Appendix G.*

OPEN BURNING BANS – 401 KAR 63:005

In 2005, Kentucky revised the open burning regulation to prohibit most types of open burning in moderate ozone nonattainment areas within Kentucky during the period of May-September when ozone is most likely to form. A copy of 401 KAR 63:005, *Open burning*, is located at **http://www.lrc.ky.gov/kar/401/063/005.htm.** This requirement continues in the Kentucky portions of the Cincinnati-Hamilton 8-hour ozone maintenance area counties of Boone, Campbell, and Kenton (*Appendix G*). The more stringent burning restrictions will increase

particle reductions across the Kentucky portion of the $PM_{2.5}$ nonattainment area during May-September.

FUGITIVE EMISSIONS – 401 KAR 63:010

For Kentucky, 401 KAR 63:010, *Fugitive emissions*, provides for the control of fugitive emissions in the state and can be found at **http://www.lrc.ky.gov/kar/401/063/010.htm**

CLEAN AIR INTERSTATE RULE (CAIR) – 401 KAR 51:210-230

On March 10, 2004, the U.S. EPA promulgated the CAIR. In response to the CAIR, Kentucky developed regulations 401 KAR 51:210, *CAIR NO_X annual trading program*; 401 KAR 51:220, *CAIR NO_x ozone season trading program*; and 401 KAR 51:230, *CAIR SO_2 trading program;* which became effective February 2, 2007.

Under the rules, Kentucky has caps as follows:

- Annual NOx: 83,205 tons for 2009-2014 and
  69,337 tons for 2015 and each year thereafter;
- Ozone season NOx: 36,109 tons for 2009-2014 and
  30,651 tons for 2015 and each year thereafter;
- Annual SO_2: 188,773 tons for 2010-2014 and
  132,141 tons for 2015 and each year thereafter.

The State's NOx allocations have been distributed based on allocation methodologies in regulations 401 KAR 51:210 (**http://www.lrc.state.ky.us/KAR/401/051/210.htm**) and 401

KAR 51:220 (**http://www.lrc.state.ky.us/KAR/401/051/220.htm**). The U.S. EPA will determine the SO_2 allocations, which are based on the acid rain program (**http://www.lrc.state.ky.us/KAR/401/051/230.htm**). This rule does not preclude Kentucky from adopting additional emission reduction requirements for covered sources if necessary to attain or maintain an ambient air quality standard (*Appendix G*).

The intent of the CAIR program was for national NO_x emissions to be cut from 4.5 million tons in 2004, to a cap of 1.5 million tons by 2009, and 1.3 million tons in 2018 in 28 eastern states. As a result of CAIR, the U.S. EPA projected that in 2009 Kentucky emissions of NO_x will decrease from a baseline of 176,00 tons per year without CAIR to 107,000 tons per year with CAIR. Projections also demonstrated that in 2010, emissions of SO_2 will decrease from a baseline of 447,000 tons per year without CAIR to 341,000 tons per year with CAIR. And by 2015, the U.S. EPA projects emissions of NO_x will decrease further to 77,000 tons per year while emissions of SO_2 will decrease to 270,000 tons per year within Kentucky. (Source: http://www.epa.gov/CAIR/ky.html)

As mentioned previously (page 8), Kentucky has not incorporated these expected CAIR reductions into the redesignation request inventories and projections. It should also be noted that Kentucky's SIP-approved NOx SIP Call program and regulations, and the CAIR program and regulations, are still in place and providing reductions.

All controls noted thus far for redesignation are expected to continue into the future. Those control measures will continue providing reduction for particulate precursors and emissions throughout the maintenance period.

In addition, various maximum available control technology (MACT) rules will be implemented throughout the maintenance period, providing additional particulate controls. These include:

MACT CONTROLS

- Industrial Boiler/Process Heater/RICE MACTs. The U.S. EPA issued final rules to substantially reduce emissions of toxic air pollutants from industrial, commercial and institutional boilers, process heaters and from stationary reciprocating internal combustion engines (RICE). These rules reduced emissions of a number of toxic air pollutants, including hydrogen chloride, manganese, lead, arsenic and mercury by 2009. This rule also reduces emissions of SO_2 and PM in conjunction with the toxic air pollutant reductions. The applied MACT control efficiencies were 4% for SO_2 and 40% for PM_{10} and $PM_{2.5}$. The U.S. EPA's industrial boiler MACT rules were vacated on June 8, 2007. The VISTAS states decided to leave these controls in the modeling since it is believed that by 2018 the U.S. EPA will have re-promulgated a boiler MACT rule or states will have addressed the issue through state rulemaking.

- Combustion Turbine MACT. The projection inventories do not include the NO_x co-benefit effects of the MACT regulations for gas turbines or stationary reciprocating internal combustion engines.

- VOC 2-, 4-, 7-, and 10-year MACT Standards. Various point source MACTs and associated emission reductions as implemented and to be implemented. Reductions occurring before 2002 were assumed to be accounted for in the base year inventory.

Section 110 and Part D requirements [CAA Section 107(d)(3)(E)(v)]

For purposes of redesignation, a state must meet all requirements of Section 110 and Part D of the CAA that were applicable prior to submittal of the complete redesignation request. Subpart 1 of Part D consists of general requirements applicable to all areas which are designated nonattainment based on a violation of the NAAQS. Subpart 4 of Part D consists of more specific requirements applicable to particulate matter (specifically to address PM_{10}). However, for the purpose of implementing the 1997 $PM_{2.5}$ standard, the U.S. EPA's Implementation Rule stated Subpart 1, rather than Subpart 4, is appropriate for the purpose of implementing $PM_{2.5}$ (72 FR 20589).

SECTION 110(A) REQUIREMENTS

Section 110(a) of Title I of the CAA contains the general requirements for a SIP. Section 110(a)(2) provides that the implementation plan submitted by a state must have been adopted by the state after reasonable public notice and hearing, and that, among other things, it must include: enforceable emission limitations and other control measures, means or techniques necessary to meet the requirements of the CAA; provide for establishment and operation of appropriate devices, methods, systems and procedures necessary to monitor ambient air quality; provide for implementation of a source permit program to regulate the modification and construction of any stationary source within the areas covered by the plan; include provisions for the implementation

of Part C, prevention of significant deterioration (PSD) and Part D, NSR permit programs; include criteria for stationary source emission control measures, monitoring, and reporting; include provisions for air quality modeling; and provide for public and local agency participation in planning and emission control rule development. In Kentucky's September 8, 2009, infrastructure SIP submission (*Appendix G*), Kentucky verified that the State fulfills the requirements of Section 110(a)(2) of the Act.

Section 110(a)(2)(D) also requires State plans to prohibit emissions from within the State which contribute significantly to nonattainment or maintenance areas in any other State, or which interfere with programs under Part C to prevent significant deterioration of air quality or to achieve reasonable progress toward the national visibility goal for Federal class I areas (national parks and wilderness areas). In order to assist States in addressing their obligations regarding regionally transported pollution, the U.S. EPA finalized CAIR to reduce SO_2 and NO_x emissions from large EGUs. Kentucky has met the requirements of the federal CAIR to reduce NO_x and SO_2 emissions contributing to downwind states. On October 4, 2007, the U.S. EPA published approval of Kentucky's CAIR program, which can be found in Kentucky Administrative Regulations 401 KAR 51:210, KAR 51:220 and KAR 51:230, effective December 3, 2007 (*Appendix G*).

On July 6, 2010, the U.S. EPA proposed a replacement to the CAIR program with the Transport Rule in 75 FR 45210. Upon finalization, the Transport Rule will continue to provide the reductions, and likely even greater reductions, that will be necessary for maintenance of the annual $PM_{2.5}$ standard to occur.

EMISSION INVENTORY

The U.S. EPA's redesignation guidance requires the submittal of a comprehensive inventory of $PM_{2.5}$ precursor emissions which include primary particles (i.e. organic carbon, crustal matter, and elemental carbon), SO_2, and NO_x, representative of the year when the area achieves attainment of the annual $PM_{2.5}$ air quality standard. As mentioned previously (pages 3 and 8), VOC and NH_3 are not addressed. Kentucky also must demonstrate that the improvement in air quality between the year that violations occurred and the year that attainment was achieved is based on permanent and enforceable emission reductions. Other emission inventory related requirements include a projection of the emission inventory to a year at least 10 years following redesignation; a demonstration that the projected level of emissions is sufficient to maintain the annual $PM_{2.5}$ standard; and a commitment to provide future updates of the inventory to enable tracking of emission levels during the 10-year maintenance period.

The emissions inventory development and emissions projection discussion below, with the exception of the mobile (on-road) emissions inventory and projections, identifies procedures used. Specific emissions data are provided for all counties, including those in Ohio, Kentucky and Indiana. Kentucky, Ohio, and Indiana emissions data were also obtained though the LADCO emissions inventory and projections. In this document, references to LADCO include the Midwest Regional Planning Organization. All of these inventories and emissions projections were prepared using similar methodologies. Mobile emissions inventories and projections for all counties were prepared by the Ohio, Kentucky, Indiana Regional Council of Governments (OKI).

Kentucky's 2005 Base Year was developed per procedures described in "Development of 2005 Base Year Growth and Control Factors for Lake Michigan Air Directors Consortium (LADCO) – Final Report" and provided in *Appendix D*. Kentucky's base year inventory and projected interim years are shown in Tables 16-27. Ohio's and Indiana's base year inventory and projected interim years are shown in Tables 31-45.

Kentucky's point, area, and nonroad sources were developed by LADCO as described in "Emission Inventory Assistance: 2005 Base Year Biogenic and Other (non-LADCO) State Emissions" in *Appendix D*. However, biogenic emissions are not included in these inventory summaries.

The on-road mobile source sector was addressed with specific $PM_{2.5}$ and NO_x modeling by OKI Regional Council of Governments, described in "Mobile Source Emissions Inventory for Cincinnati $PM_{2.5}$ Nonattainment Area – August 2010" and included in *Appendix E*. The mobile inventory is shown for each Kentucky county in Tables 3 through 5, and summarized in Table 6. The Ohio counties are shown in Tables 7 through 11, and summarized in Table 12. The on-road emission estimation totals for the nonattainment area and summarized in Table 13.

EMISSION PROJECTION METHODOLOGY

The U.S. EPA's redesignation guidance requires the submittal of a comprehensive inventory of $PM_{2.5}$ precursor emissions which include primary particles (i.e. organic carbon, crustal matter, and elemental carbon), SO_2, and NOx, representative of the year when the area achieves attainment of the annual $PM_{2.5}$ air quality standard.

One of the planning elements listed in the Calcagni memorandum dated September 4, 1992, (*Appendix A*) required for attainment redesignation purposes is developing a projection inventory that indicates the area will remain in attainment and which includes emission projections for at least 10 years after the U.S. EPA's official redesignation approval. Kentucky's projection inventory through the year 2021, and the methodology for performing that inventory, is located in *Appendix D*.

The emissions inventory is broken down into four components: point, area, highway mobile, and non-highway mobile sources. Using 2008 as the attainment year, the subsequent years were chosen at appropriate intervals and project maintenance for at least a 10-year period pending approval of the revision of the SIP.

The base year of 2005, the attainment year of 2008 for Kentucky (point, area and nonroad sources), as well as 2015 and 2021, were projected by LADCO using their 2005 Base Year Inventory methodology as provided in *Appendix D.*

Mobile emissions for the base year of 2005, the attainment year of 2008, the interim year of 2015, and the maintenance year of 2021 for the highway mobile, were developed by OKI using the U.S. EPA's Motor Vehicle Emissions Simulator (MOVES). The technical support document is provided in *Appendix E*. The two separate motor vehicle emission budgets are listed in Tables 14 and 15.

ADDITIONAL INTERPOLATED INTERIM PROJECTION YEARS FOR KENTUCKY

For this demonstration the U.S. EPA Region IV has requested that Kentucky provide two additional inventory interim years of 2011 and 2018 for all sectors interpolated through calculations described here:

There is a two-step calculation process to estimate the emissions of the interpolated year. The first step is to calculate the emissions growth rate, using the following formula.

Interpolated Year Emissions growth factor = EXP(RATE(n,,-PY,FY))^ni
Where n = number of years between the Past Year and the Future Year
PY = Past Year
FY = Future Year
ni = number of years between the Past Year and the chosen interpolated year

The second step is to multiply the calculated emissions growth rate by the Past Year emissions.

Interpolated Emissions = Interpolated Year Emissions growth factor x Past Year emissions

To calculate the interpolated year of 2011 using the formulas above, the two-step methodology can be applied in the following manner. First,

2011 Emissions growth factor = EXP(RATE(7,,-2008 emissions,2015 emissions))^3
Now the second calculation can interpolate the 2011 emissions by using the following formula.

Interpolated 2011 Emissions = Interpolated Year Emissions growth factor x Past Year emissions

The same methodology was used to calculate the interpolated year of 2018.

2018 Emissions growth factor = EXP(RATE(7,,-2015 emissions,2021 emissions))^3

Interpolated 2018 Emissions = Interpolated Year Emissions growth factor x Past Year emissions

The 2008 attainment year shows attainment of the NAAQS and the decrease in emission levels discussed in the emissions inventory (2008-2011-2015-2018-2021), which supports a redesignation to attainment for the Kentucky portion of the Cincinnati-Hamilton area based on the requirements in Section 107(d)(3)(E) of the CAA.

The Kentucky counties' base year inventory, attainment, interim, and maintenance year inventory for all sectors are provided in Tables 16-27.

Safety margins for the Kentucky portion are provided in Tables 28-30.

The Ohio and Indiana counties and safety margins are provided in Tables 31- 45.

MAINTENANCE PLAN

Section 107(d)(3)(E) of the CAA mandates that for an area to be redesignated to attainment, the U.S. EPA must approve a maintenance plan that meets the requirements of Section 175A of the CAA. The maintenance plan must constitute a SIP revision and provide for maintenance of the air quality in an affected area for at least 10 years after redesignation. Kentucky has chosen to project emissions through the year 2021.

The maintenance plan includes an emissions inventory for the attainment year (2008), projected inventories through 2021, a commitment to maintain the existing monitoring system, and contingency measures as may be necessary should the area fail to continue to maintain the annual fine particulate NAAQS.

A maintenance demonstration requires comparison of the projected emissions inventory with the baseline inventory. If the projected emissions remain at or below the baseline emissions, there is a demonstration of maintenance. If, however, the projected emissions are above the baseline, then additional measures are required to ensure the projected emissions will remain at or below the baseline emissions.

Tables 3 through 6 detail the projection of emissions through 2021. Boone, Campbell and Kenton counties' projected 2021 total emissions for $PM_{2.5}$, NO_x, and SO_2 are below the 2008 total emissions, thus demonstrating continued maintenance of the annual fine particulate standard. Emissions for 2005 are provided to be consistent with Ohio and Indiana's submittal to indicate the change in emissions up to the attainment year.

Documentation showing how emissions were grown is included in *Appendix D,* including the Technical Support Documents "E2: TSD Version IV 042508" for with CAIR and "E3: TSD Supplement without CAIR modeling."

POINT SOURCES

For this inventory purpose, the source emissions are calculated from data collected annually from the sources. This information is stored in an existing Kentucky Emissions Inventory System database and that information has been uploaded into the U.S. EPA National Emissions Inventory (NEI) system.

Information regarding how growth was projected for point sources is provided in *Appendix H* which contains the LADCO documentation regarding the emission inventory development and related Technical Support Documents.

AREA SOURCES/NON-HIGHWAY MOBILE SOURCES

As previously noted, the emissions and projections for area and nonhighway mobile sources were provided by LADCO. A more thorough discussion and documentation of these emissions and projections is provided in *Appendix D.*

MOBILE SOURCES

To calculate emissions from mobile sources, the division obtained mobile source emission projections from OKI in Cincinnati, Ohio. This organization is the metropolitan planning organization for the Greater Cincinnati area. These data and documentation on how these projections were performed can be found in *Appendix E,* including input and output files for those projections.

On-Road Emission Estimations

In coordination with the Ohio Department of Transportation (ODOT), OKI utilizes a regional travel demand forecast model to simulate traffic in the area and to forecast traffic flows for given growth expectations. The model has been validated to observed traffic volumes for the model base year 2005. The model is primarily used as a long range planning tool to evaluate the transportation system including determination of locations where additional travel capacity may be needed and to determine the infrastructure requirements necessary to meet that need. It is also used as a tool for air quality purposes to estimate the total emissions of pollution caused by vehicles in the area. The travel demand forecasting model is used to predict traffic volumes vehicle miles traveled (VMT), travel speeds, and the U.S. EPA computer program called MOVES is used to calculate emissions per mile. The product of these is the total amount of pollution emitted by the on-road vehicles for the area.

OVERVIEW OF MOBILE MODELING

The U.S. EPA published a Federal Register notice of availability on March 2, 2010 (*Appendix B*), to approve MOVES. Upon publication of the Federal Register notice, MOVES became the U.S. EPA's approved motor vehicle emission factor model for estimating VOCs, NO_x, CO, PM_{10} and $PM_{2.5}$ and other pollutants and precursors from cars, trucks, motorcycles, and buses by state and local agencies. MOVES is a computer program designed by the U.S. EPA to estimate air pollution emissions from mobile sources. MOVES replaces the U.S. EPA's previous emissions model for on-road mobile sources, MOBILE6.2. MOVES can be used to estimate exhaust and evaporative emissions as well as brake and tire wear emissions from all types of on-road vehicles.

The CAA requires the U.S. EPA to regularly update its mobile source emission models. The U.S. EPA continuously collects data and measures vehicle emissions to make sure the Agency has the best possible understanding of mobile source emissions. This assessment, in turn, informs the development of the U.S. EPA's mobile source emission models. MOVES represents the Agency's most up-to-date assessment of on-road mobile source emissions. MOVES also incorporates several changes to the U.S. EPA's approach to mobile source emission modeling based upon recommendations made to the Agency by the National Academy of Sciences.

The U.S. EPA believes that MOVES should be used in ozone, CO, PM, and NO_x SIP development as expeditiously as possible. The CAA requires that SIP inventories and control measures be based on the most current information and applicable models that are available when a SIP is developed.

Regarding transportation conformity, the U.S. EPA and U.S. DOT intend to establish a two-year grace period before MOVES is required for new transportation conformity analyses.

The MOVES more detailed approach (when compared with the previous MOBILE model) to modeling allows the U.S. EPA to easily incorporate large amounts of in-use data from a wide variety of sources, such as data from vehicle inspection and maintenance (I/M) programs, remote sensing device (RSD) testing, certification testing, portable emission measurement systems (PEMS), etc. This approach also allows users to incorporate a variety of activity data to better estimate emission differences such as those resulting from changes to vehicle speed and acceleration patterns. MOVES has a graphical user interface which allows users to more easily

set up and run the model. MOVES database-centered design provides users much greater flexibility regarding output choices. Unlike earlier models which provided emission factors in grams-per-mile in fixed output formats, MOVES output can be expressed as total mass (in tons, pounds, kilograms, or grams) or as emission factors (grams-per-mile and in some cases grams-per-vehicle). Output can be easily aggregated or disaggregated to examine emissions in a range of scales, from national emissions impacts down to the emissions impacts of individual transportation projects. The database-centered design also allows the U.S. EPA to update emissions data incorporated in MOVES more easily and will allow users to incorporate a much wider array of activity data to improve estimation of local emissions. For example, the improvements in MOVES will allow project-level $PM_{2.5}$ emissions to be estimated.

OKI utilized the U.S. EPA's emissions model MOVES to develop emissions factors for SO_2, NO_x and $PM_{2.5}$. Further details on the use of MOVES are found on *Appendix E*. Transportation system performance was estimated using the OKI Travel Demand Model Version 7.6. The model uses demographic and land use data and capacity and free-flow speed characteristics for each roadway segment in the network to produce a "loaded" highway network with forecasted traffic volumes with revised speeds based on specified speed/capacity relationships.

Travel analysis zones are the basic geographic unit for estimating travel in the OKI model. The OKI region is subdivided into 1608 traffic analysis zones to permit detail as well as manageability. A variety of socioeconomic data items are used in the OKI transportation planning process. These data are used primarily to forecast future travel patterns by serving as

independent variables in OKI trip generation equations. The following categories of planning data are utilized:

- Population
- Households
- Household vehicles
- Employment
- Labor force participation
- Area type

The principal data requirements of the OKI travel demand forecasting model are population and employment, from these variables other characteristics including household, labor force, and personal vehicles may be derived (OKI 2030 Regional Transportation Plan 2008 Update provides a complete demographic overview of the region).

OKI utilizes both base year (2005) and future year data (2010, 2020 and 2030) in the planning process. Planning data are maintained at the Traffic Analysis Zone (TAZ) level, and originate in the 2000 Census of Population and Housing. Base year 2005 and future year data for each variable are developed through various methods.

OKI's Travel Demand Model has been validated to observed traffic volumes for the model base year 2005. The modeling network encompasses the entire $PM_{2.5}$ nonattainment area. The modeling network also includes Greene, Miami, and Montgomery counties in Ohio and the remainder of Dearborn County, Indiana. The differences between estimated VMTs and 2005 observed VMT is less than 1%. A highway screenline analysis compares the screenline observed and simulated traffic volume discrepancies with the ODOT standard of maximum desirable

deviation. The comparison shows that the model performs at a satisfactory level and all the errors were under the ODOT curve (OKI's 2007 report, "OKI/MVRPC Travel Demand Model Methodology/Validation Report"). For the calibration, OKI used over 3000 traffic counts collected through 2006 by the ODOT, the Kentucky Transportation Cabinet, many county and local governments, transportation engineering consultants, and OKI. These traffic counts cover nearly 50% of the links in the OKI portion of the modeling network. The methodology provides consistency with past emission inventory and conformity analysis work performed by OKI.

OKI incorporates a variety of sources of local data to both improve and confirm the accuracy of VMT, as well as other travel-related parameters. Free flow speeds used on the highway and transit networks are based on travel time studies performed locally. An OKI post-processing program uses the loaded highway network to generate VMT by hour, VMT by speed distribution, and VMT by facility type. These tables are then included as input into MOVES. The VMT by hour tables utilize hourly traffic distribution and directional split factors for different roadway types as developed by OKI. The main source of the data was the permanent traffic counting stations located throughout the OKI region for the years of 1998-2002. These data were supplemented with data collected at coverage count stations (locations with counts taken on only one-two days). The stations were classified by area type (urban and rural) and functional classification (freeway, arterial and collector). Speeds representing various "loaded" conditions (with traffic volumes) are estimated using techniques from the 1997 Highway Capacity Manual. This permits the estimation of speeds as conditions vary from hour to hour on the different facility types throughout the region. The post-processing program performs the appropriate summation by area and roadway type as well as regional totals. OKI has also

developed seasonal conversion factors to adjust traffic volumes to summer conditions. The factors were derived from local data collected at permanent traffic counting stations during 1994-1997 utilizing the average daily traffic monthly conversion factors for June, July, and August.

ON-ROAD MOBILE EMISSION ESTIMATIONS FOR THE KENTUCKY PORTION

Tables 3 through 6 contain the results of the emissions analysis for the appropriate years. All emissions estimations are expressed in tons per year.

Motor Vehicle Emissions Budgets

Table 14 and Table 15 contain the motor vehicle emissions budgets for the Cincinnati-Hamilton area. For planning purposes, budgets are established for the combined Ohio and Indiana portions and for the separate Kentucky portion.

Table 14 - Mobile Vehicle Emissions Budget for the Ohio and Indiana portion

	2015 Estimated Emissions	2015 Mobile Safety Margin Allocation*	2015 Total Mobile Budget	2021 Estimated Emissions	2021 Mobile Safety Margin Allocation*	2021 Total Mobile Budget
PM2.5 (tpy)	1598.67	79.93	1678.60	1128.35	112.84	1241.19
NOx (tpy)	31,064.20	4659.63	35,723.83	18,911.05	2836.65	21,747.71
Annual VMT	14,830,453,053	-	-	15,521,916,278	-	-

*The 5 to15 percent margin of safety was calculated by taking 5 to15 percent of the mobile source emission estimates

Table 15 - Mobile Vehicle Emissions Budget for the Kentucky portion

	2015 Estimated Emissions	2015 Mobile Safety Margin Allocation*	2015 Total Mobile Budget	2021 Estimated Emissions	2021 Mobile Safety Margin Allocation*	2021 Total Mobile Budget
PM2.5 (tpy)	371.11	18.56	389.67	275.38	27.54	302.92
NOx (tpy)	6,996.22	1049.43	8,045.65	6,421.15	963.17	7,384.32
Annual VMT	3,931,385,741	-	-	5,452,303,073	-	-

*The 5 to15 percent margin of safety was calculated by taking 5 to15 percent of the mobile source emission estimates

The above budgets for the Ohio and Indiana portion and for the Kentucky portion of the area, agreed upon as part of the interagency consultation process, include the emission estimates calculated for 2015 and 2021 (from Table 6 and Table 12) with an additional 5% margin of safety allocated for $PM_{2.5}$ in 2015, 10% margin of safety allocated to $PM_{2.5}$ in 2021 and 15% margin of safety allocated to NO_x in 2015 and 2021. "Safety margin" means the amount by which the total projected emissions from all sources of a given pollutant are less than the total emissions that would satisfy the applicable requirement for reasonable further progress, attainment, or maintenance.

In an effort to accommodate future variations in travel demand models and VMT forecast when no change to the network is planned, the states consulted with the U.S. EPA to determine a reasonable approach to address this variation. Based on this discussion, a 5 to15 percent margin of safety allocation was agreed upon and has been added to the mobile emissions estimates for the nonattainment area.

All methodologies, the latest planning assumptions, and the safety margins allocations were determined through the interagency consultation process described in the Transportation Conformity Memorandum of Understanding (MOU) among OKI, ODOT, and Ohio EPA.

A 5 to 15 percent margin of safety is appropriate because: 1) there is an acknowledged potential variation in VMT forecast and potential estimated mobile source emissions due to expected modifications to TDM and mobile emissions models; and 2) the total decrease in emissions from all sources is sufficient to accommodate this 5 to 15 percent allocation of safety margin (as defined in 40 C.F.R. 93.101) to mobile sources while still continuing to maintain the total emissions in the Cincinnati-Hamilton area well below the 2008 attainment level of emissions.

The 5 to 15 percent margin of safety was calculated by taking 5 to 15 percent of the mobile source emission estimates. Safety margin, as defined by the conformity rule, looks at the total emissions from all sources in the nonattainment area. The actual allocation is less than 5 to 15 percent of the total emission reduction from all sources as can be seen from Table 49.

In summary, for all three states combined, the mobile budget safety margin allocation translates into an additional 98.49 tpy for $PM_{2.5}$ and 5,709.06 tpy for NO_x for 2015 and an additional 140.38 tpy for $PM_{2.5}$ and 3,799.82 tpy for NO_x for 2021.

When compared to the overall safety margin, as defined in 40 C.F.R. 93.101, it is evident this allocation is significantly below the total safety margin for this area.

The current $PM_{2.5}$ and NO_x mobile budgets for the fine particle NAAQS will no longer be applicable either after the effective date of the approved redesignation or after the effective date of any U.S. EPA action approving a finding that the $PM_{2.5}$ and NO_x conformity budgets included in this submittal are adequate for transportation conformity purposes, whichever date comes first.

Finally, it is important to underline that all motor vehicle emission budgets in this redesignation submittal, which are based on MOVES, will replace previous motor vehicle emission budgets on attainment demonstration submittals based on MOBILE6.2.

DEMONSTRATION AND PROJECTED EMISSIONS WITH SAFETY MARGINS

KENTUCKY PORTION OF THE NONATTAINMENT AREA

The 2005 and 2008 actual $PM_{2.5}$ emissions data below generally contains particulate fraction emissions only and not the condensible fractions as Ohio EPA did not have a consistent reporting requirement at those years. The U.S. EPA IPM modeling was used to generate future year EGU emissions with the CAIR program. The IPM modeling added additional $PM_{2.5}$ condensible emissions into future years. Therefore, comparing base and attainment year emissions with the

future year predictions is not accurate in the IPM CAIR modeling. This step leads to a false perception of significant $PM_{2.5}$ emissions growth. Modeling performed by LADCO, without CAIR, did not incorporate added condensible fraction emissions. Although Ohio EPA has stated that it is most appropriate to evaluate future year emissions that include the CAIR program, because of this flaw it will be more accurate and appropriate for the purposes of $PM_{2.5}$ to evaluate future year emissions without the CAIR program.

THE OHIO AND INDIANA PORTION OF THE NONATTAINMENT AREA

Ohio EPA has revised the Butler County, Ohio $PM_{2.5}$, NO_x and SO_2 Emissions Inventory (non-EGU) to incorporate the total emissions reduction credits available and used to offset the allowed emissions of a major source modified within the maintenance area that will begin operating during the maintenance period. The total emissions included in the inventory, and in all the Butler County tables below for this facility in 2015 and 2021, are 117.81 tpy $PM_{2.5}$, 479.57 tpy NOx and 1209.92 tpy SO_2. The emissions increase does not significantly impact the safety margin for this area or prevent the area from maintaining the standard in future years.

Particulate Matter ($PM_{2.5}$)

(CONTINUED NEXT PAGE)

TOTAL OF ALL EMISSIONS

It is important to recognize in Tables 46 through 48 the differences between the 2008 attainment year tpd for each pollutant and the projected 2021 maintenance tpd for each pollutant. Table 49 shows that for the combined nonattainment area, projected 2021 emissions for all pollutants are less than 2008 attainment year levels.

$PM_{2.5}$, NO_x, and SO_2 Projected Emission Decreases

Table 49 - **Cincinnati-Hamilton Area Comparison of 2008 attainment year and 2015 interim and 2021 projected emission estimates (**tpy)

	2008 Base	2015 Interim	2015 Projected Decrease	2021 Maintenance	2021 Projected Decrease
$PM_{2.5}$	8,904.64	8,634.55	270.09	8,202.63	702.01
NO_x	148,706.15	105,712.02	42,994.13	78,819.13	69,887.02
SO_2	117,016.14	112,250.26	4,765.88	88,510.27	28,505.87

As shown in the table above (Table 49), $PM_{2.5}$ emissions in the nonattainment area are projected to decrease by 270.09 tpy in 2015 and 702.01 tpy in 2021. NO_x emissions in the nonattainment area are projected to decrease by 42,994.13 tpy in 2015 and 69,887.02 tpy in 2021. SO_2 emissions in the nonattainment area are projected to decline by 4,765.88 tpy in 2015 and 28,505.87 in 2021.

Area source emissions and, to a lesser extent, point sources show an increase due to expectations that the population will grow in this area; however, cleaner vehicles and fuels are expected to be in place in 2009 and 2018, and the Transport Rule will be implemented in 2012 and 2014. These programs should cause an overall drop in all three pollutants emissions. Decreases from the U.S.

EPA rules covering Tier 2 Motor Vehicle Emissions Standards and Gasoline Sulfur Control Requirements (*FR* Feb 10, 2000 Vol. 65 No. 28), Highway Heavy-Duty Engine Rule (*FR* Oct. 21, 1997 Vol. 62 No. 203), and the Non-Road Diesel Engine Rule (*FR* Oct. 23, 1998 Vol. 63, No. 205) are factored into the changes.

PLAN TO MAINTAIN AIR QUALITY

The Commonwealth of Kentucky and the U.S. EPA have instituted previously mentioned control strategy programs that will remain enforceable and are hereby submitted as a plan to maintain air quality which meets the NAAQS for the annual $PM_{2.5}$ standard. Sources are prohibited from reducing emission controls following the redesignation of the area.

In addition to these measures, further reductions will be achieved through federal regulations such as the "FIP to Reduce Interstate Transport of Fine Particulate Matter and Ozone", published as a proposed rule on August 2, 2010. This rule is proposing to further regulate EGUs in 32 states to limit NO_x and SO_2 emissions.

EXISTING MONITORING NETWORK

In addition to the maintenance plan discussed above, the existing $PM_{2.5}$ monitoring network located within the Kentucky counties of the Cincinnati-Hamilton $PM_{2.5}$ Nonattainment area has been approved by the U.S. EPA. The monitoring network will continue to remain operational in accordance to 40 CFR 58, with no reductions.

CONTINGENCY MEASURES

Future reviews of actual emissions for this redesignated area will be performed using the latest emission factors, models, and methodologies. For these periodic inventories, Kentucky will review the assumptions made for the purpose of the maintenance demonstration concerning projected growth of activity levels. If any of these assumptions appear to have changed substantially, Kentucky will re-project emissions.

In the event that a measured value of the weighted annual mean is 15.5 micrograms per cubic meter or greater occurs in a single calendar year in any portion of the maintenance area, the state will evaluate existing control measures to see if any further emission reduction measures should be implemented at that time.

In the event of a monitored violation of the annual $PM_{2.5}$ NAAQS in the Cincinnati-Hamilton maintenance area, the Commonwealth commits to adopt, within nine months, one or more of the following contingency measures to re-attain the standard. All regulatory programs will be implemented within 18 months after the triggering monitored violation.

- Implementation of a program to require additional emission reductions on stationary sources;
- Implementation of fuel programs, including incentives for alternative fuels;
- Restriction of certain roads or lanes to, or construction of such roads or lanes for use by, passenger buses or high-occupancy vehicles;
- Trip-reduction ordinances;
- Employer-based transportation management plans, including incentives;
- Programs to limit or restrict vehicle use in downtown areas, or other areas of emission concentration, particularly during periods of peak use;
- Programs for new construction and major reconstructions of paths or tracks for use by pedestrians or by non-motorized vehicles when economically feasible and in the public interest;
- Diesel reduction emission strategies, including diesel retrofit programs

Kentucky also reserves the right to implement other contingency measures if new control programs should be developed and deemed more advantageous for the area.

Section 175A(b) of the CAA requires that eight years after formal redesignation, the state continues to provide for maintenance of the standard by submitting another maintenance plan that covers an additional 10 years. If this requirement remains applicable for this area, Kentucky commits to submit to the U.S. EPA a plan for future maintenance of the standard in Boone, Campbell and Kenton counties as required.

PUBLIC PARTICIPATION

Kentucky held a public hearing to receive comments on this proposed redesignation request on December 15, 2010 at the offices of the Northern Kentucky Area Development District. A copy of the public hearing notice and a copy of the advertisements are included in *Appendix I*.

A copy of the Energy and Environment Cabinet's response to comments received during that public review period is included as *Appendix I*.

Appendix A

U.S. EPA Memorandums

regarding

Redesignations

MEMORANDUM

SUBJECT: Processing of State Implementation Plan (SIP) Submittals

FROM: John Calcagni, Director
Air Quality Management Division, OAQPS (MD-15)

TO: Director, Air, Pesticides and Toxics Management Division, Regions I and IV
Director, Air and Waste Management Division, Region II
Director, Air, Radiation, and Toxics Division, Region III
Director, Air and Radiation Division, Region V
Director, Air, Pesticides, and Toxics Division, Region VI
Director, Air and Toxics Division, Regions VII, VIII, IX, and X

This memorandum provides guidance concerning the processing of SIP submittals. In general, there are three situations that can occur related to each required submittal: the State may fail to submit the required plan, the State may make a submittal that is not complete, or the State may make a complete submittal. Once a State submits a SIP and the Environmental Protection Agency (EPA) has determined that the submittal is complete, EPA must either approve or disapprove the submittal within a specified time period. However, if the State fails to make a required submittal or makes a submittal that is determined to be incomplete, the sanctions and Federal implementation plan (FIP) provisions of sections 179 and 110(c), respectively, will be triggered. In addition, disapproval of a submittal also triggers the sanctions and FIP provisions. These provisions are discussed in further detail in this memorandum.

There are, however, three alternatives to full approval or full disapproval of a complete SIP submittal: partial approval,

limited approval, and conditional approval. Each of these is discussed in more detail below along with some guidance as to when each might be used. In addition, Attachment 1 to this memorandum contains several examples of how these may be used. Attachment 2 to this memorandum is a table that summarizes the requirements discussed below.

Partial Approval/Disapproval

Section 110(k)(3) of the amended Clean Air Act (Act) addresses the situation in which an entire submittal, or a separable portion of a submittal, meets all applicable requirements of the Act. Where the entire submittal meets all the requirements of the Act, EPA will fully approve the entire submittal. In the case where a separable portion of the submittal meets all of the applicable requirements, partial approval may be used to approve that part of the submittal and disapprove the remainder. It is important that the two parts of the submittal be separable. By separable, EPA means that the action it anticipates taking will not result in the approved rule(s) being more stringent than the State anticipated. See Bethlehem Steel Corp. v. Gorsuch, 742 F. 2d 1028 (7th Cir. 1984); Indiana and Michigan Elec. Co. v. U.S. E.P.A., 733 F. 2d 489 (7th Cir. 1984). For example, EPA cannot approve part of a submittal that specifies control measures and disapprove the part that specifies the test methods associated with those control measures. The EPA has frequently taken a partial approval approach in the past to process groups of rules that are submitted together. The EPA can approve some of the rules and disapprove the rest as long as the rules that are disapproved do not affect those that are approved. The disapproval of any part of a required SIP submittal starts the clocks discussed above for sanctions and FIP's.

Limited Approval/Disapproval

In some cases, a submittal may contain certain provisions that meet the applicable requirements of the Act along with other provisions that do not meet the requirements, and the provisions are not separable. Although the submittal may not meet all of the applicable requirements, EPA may want to consider whether the submittal as a whole has a strengthening effect on the SIP. If that is the case, limited approval may be used to approve a rule that strengthens the existing SIP as representing an improvement over what is currently in the SIP and as meeting some of the applicable requirements of the Act.

The Act does not expressly provide for limited approvals.

Rather, EPA is using its "gap-filling" authority under section 301(a) of the Act in conjunction with the section 110(k)(3) approval provision to interpret the Act to provide for this type of approval action.

Through a limited approval, EPA would concurrently, or within a reasonable time thereafter, disapprove the rule, under the relevant provision(s) of Part D, for not meeting all of the applicable requirements of the Act. As with the limited approval action the limited disapproval is a rulemaking action, and it is subject to notice and comment. Under section 110(k), EPA must take final rulemaking action on SIP submittals within 12 months of the date EPA determines the submittal is complete or the submittal is automatically deemed to be complete if EPA fails to make a completeness determination. As a general matter, although the statute directs EPA to act within that timeframe, EPA's failure to finalize the disapproval portion of the action within that 12-month timeframe will not affect the validity of any prior or subsequent limited approval or limited disapproval.[1] The EPA's failure to take action prior to the expiration of the 12-month period could, however, subject EPA to a lawsuit to compel such an action.

A key distinction between the limited approval and a partial approval is that under a limited approval EPA's approval action goes to the entire rule. In other words, although portions of a rule prevent EPA from finding that the rule meets a certain requirement of the Act, EPA believes that the rule, as a whole, strengthens the SIP. Therefore, EPA approves the entire rule--even those portions that prohibit full approval. Likewise, when EPA issues the limited disapproval, the disapproval applies to the entire rule as failing to meet a specific requirement of the Act. The rule remains a part of the SIP, however, under the limited disapproval, because the rule strengthens the SIP. The disapproval only applies to whether the submittal meets a specific requirement of the Act and does not affect incorporation of the rule into the approved, federally enforceable SIP.

---

[1] The March 22, 1991 memorandum from John Calcagni discussed the potential impact of Abramowitz v. U.S. E.P.A., 832, F. 2d 1071 (9th Cir. 1988), on EPA's decision to split the approval and disapproval portions of a limited approval. After reevaluating that case, we believe it may have a narrower impact than initially described and, therefore, generally would not impact the timing of limited approval/disapproval actions.

The primary advantage to using the limited approval approach is to make the State submittal federally enforceable and to increase the SIP's potential to achieve additional reductions. Therefore, limited approval should not be used to approve any rule that is unenforceable for all situations--for example, a rule that lacks a test method. These rules and any other rules that do not have an overall strengthening effect on the SIP should be disapproved. Limited approval can be used, however, where the rule is unenforceable for some limited number of situations but is enforceable for the majority of situations, if the rule, as a whole, strengthens the SIP.

The disapproval coinciding with (or following) the limited approval also starts the sanctions and FIP clocks discussed above. With the limited approval EPA may or may not have a commitment from the State to correct the deficiency. The EPA may choose to use the limited approval approach (instead of conditional approval) in the case where the State has submitted a commitment as part of a rule but EPA has reason to believe that the State will not be able to meet the commitment (as discussed below). Where a limited approval/disapproval approach is taken, the notice of proposed rulemaking (NPR) should clearly identify which requirements have not been met and what action would be required on the part of the State to meet those requirements.

Conditional Approval

Under section 110(k)(4) of the Act EPA may conditionally approve a plan based on a commitment from the State to adopt specific enforceable measures within 1 year from the date of approval. If the State fails to meet its commitment within the 1-year period, the approval is treated as a disapproval. We expect that conditional approvals will be used only in rare situations that merit special consideration. We will evaluate specific types of SIP submittals [e.g., reasonably available control technology (RACT) catch-ups, particles with an aerodynamic diameter less than or equal to a nominal 10 micrometers (PM-10) SIP's] to determine whether certain elements of that type of submittal, or that type of submittal as a whole, merit conditional approval. For this reason and to ensure consistency, Regions should not use conditional approvals without input from Headquarters as to whether such an approach is appropriate. Furthermore, as any statutory deadline approaches, we may issue guidance regarding the appropriate use of conditional approval with respect to that specific requirement.

Once a determination has been made that a specific type of submittal can be considered for conditional approval, Regions

must make a determination of whether an individual State submittal should be conditionally approved. The first consideration should be whether the State has made (or agrees to make) a commitment to adopt specific enforceable measures within 1 year of EPA approval. The commitment must be made in writing by the party responsible for adopting the specified measures before the plan is conditionally approved, and the commitment must be submitted by the State.[2]

In addition, to the extent that the commitment materially alters the existing rule (in respects that the public could not reasonably have anticipated would result from the public review of the existing rule), or is a commitment to adopt an entire rule or set of rules, the commitment must be a SIP revision submittal by the State. In many cases, the determination of whether the commitment materially alters the underlying rule may be based on whether a similar issue was raised during the earlier State proceedings on the submitted rule. In general, each commitment will need to be examined to determine whether it materially alters the submitted rule. As with any SIP revision, in order for EPA to accept the commitment as a SIP revision, the State must have provided notice and public hearing on the submitted commitment. However, EPA has the discretion to parallel process commitments and in limited circumstances may propose conditional approval of the commitment and allow the State process to proceed on a parallel track.

As a general matter, the greater the extent to which a submittal is lacking in important plan elements, the less appropriate the use of conditional approval may be. It should be noted, however, that there may be circumstances under which EPA would accept a SIP revision consisting of a commitment only (without specifically adopted rules) as a candidate for conditional approval. In such cases, the commitment should also be accompanied by a work plan detailing any specific measures to be adopted, the steps that will be taken to adopt the measures,

---

[2] Although the commitment must identify the measures to be adopted and contain a schedule for adopting such measures, it is not necessary for the commitment itself to be enforceable in a State court.

and the schedule for adoption of those measures. As stated earlier, a submittal that consists entirely of a commitment will be considered a SIP revision that is subject to the State process for submitting SIP revisions, e.g., notice and a public hearing.

Where the submittal contains specifically adopted rules that need some revisions or corrections to be fully-approvable, the commitment may not need to be as comprehensive. The commitment should, however, be as explicit as possible concerning the measures that will be adopted, the steps that will be taken to adopt the measures, and the schedule for adoption of those measures.

Because the conditional approval relies on a commitment from the State, EPA would need some level of confidence that the State would be able to meet such a commitment. In making a determination as to whether a State could reasonably be expected to meet its commitment, EPA would need to consider a number of factors such as:

- the amount of technical work necessary for the measures to be adopted;
- whether adoption of the measures is expected to be controversial;
- the average length of the State adoption process;
- how far along in the process the State is; and
- the State's past track record.

It should be noted that these are only some of the factors that should be considered. Each Region, in making a determination regarding the credibility of the State's commitment, may have to look at a number of other factors. The Region should clearly explain, either in the NPR or in a technical support document, the rationale for these determinations.

In addition to the determination of whether the State's commitment is credible, the Region must make a determination as to whether it is appropriate to conditionally approve a revision on the merits of that revision. Conditional approval might typically be used in the same types of situations as the limited approval. As with the limited approval, one of the main advantages of the conditional approval approach is to make the State submittal (where the submittal contains control requirements and not just a commitment to adopt enforceable measures) federally enforceable and to increase its potential to achieve additional reductions. Because the conditionally approved submittal will become a part of the SIP, the Region

should be certain that the approval of the commitment will not weaken the existing SIP. The Region may also want to consider when the plan (or plan element) that has been submitted was due.

The NPR for a conditional approval should clearly identify which requirements are the subject of the commitment and, therefore, have not been met. In addition, both the NPR and the State's commitment should clearly identify what action is required on the part of the State. Unlike the limited approval/disapproval, the conditional approval does not immediately start the sanctions and FIP clocks. These clocks start if and when the approval is converted to a disapproval.

There are at least two ways that the conditional approval may be converted to a disapproval.[3] First, if the State fails to adopt and submit the specified measures by the end of 1 year (from the final conditional approval), or fails to submit anything at all, EPA will have to issue a finding of disapproval but will not have to propose the disapproval. That is because in the original proposed and final conditional approval, EPA will have provided notice and an opportunity for comment on the fact that EPA would directly make the finding of disapproval (by letter) if the State failed to submit anything.[4] Therefore, at the end of 1 year from the conditional approval, the Regional Administrator (RA) will send a letter to the State finding that it had failed to meet its commitment and that the SIP submittal is disapproved. The 18-month clock for sanctions and the 2-year clock for a FIP start as of the date of the letter. Subsequently, a notice to that effect will be published in the Federal Register, and appropriate language will be inserted in the Code of Federal Regulations. Similarly, if EPA receives a submittal addressing the commitment but determines that the submittal is incomplete, the RA will send a letter to the State making such a finding. As with the failure to submit, the sanctions and FIP clocks will begin as of the date of the finding

---

[3] It should be noted that this disapproval can be a limited approval/disapproval. In some cases, the Regions may want to use such an approach to retain the enforceability of control measures. The NPR should indicate if this approach is planned.

[4] To provide for this contingency, in the final conditional approval, EPA would need to provide, for example, "If the State fails to make a submittal or makes only an incomplete submittal during the time period for submittal of the rule, EPA will issue a letter to the State which converts the conditional approval to a disapproval."

letter.

Second, where the State does make a complete submittal by the end of the 1-year period, EPA will have to evaluate that submittal to determine if it may be approved and take final action on the submittal within 12 months after the date EPA determines the submittal is complete. If the submittal does not adequately address the deficiencies that were the subject of the conditional approval, and is therefore not approvable, EPA will have to go through notice-and-comment rulemaking to disapprove the submittal. The 18-month clock for sanctions and the 2-year clock for a FIP start as of the date of final disapproval. If EPA determines that the rule is approvable, EPA will propose approval of the rule. In either instance, whether EPA finally approves or disapproves the rule, the conditional approval remains in effect until EPA takes its final action.

It should be noted that EPA will conditionally approve a certain rule only once. Subsequent submittals of the same rule that attempt to correct the same specifically identified problems will not be eligible for conditional approval.

Sanctions and FIP Requirements

Actions that Trigger the Sanctions and FIP Requirements

The actions EPA has the authority to take under the sanctions and FIP provisions of the Act correspond to the different steps EPA must follow as it reviews and processes SIP submittals. As discussed previously, the Act in section 179[5] requires EPA to impose sanctions based on four types of actions (findings[6]) provided in section 179(a):

(1) a finding that a State has failed to submit a SIP, a

---

[5] Section 110(m) grants EPA broad authority to apply either sanction listed in section 179(b) " . . . at any time (or at any time after) a finding . . ." under section 179(a) with respect to any portion of the State, with certain exceptions. This memorandum is intended to address the application of sanctions under section 179. The section 179 sanctions apply only to the area for which a finding has been made.

[6] Although subsections (1)-(4) refer to findings, determinations and disapprovals, for simplicity these four actions will be referred to as "findings."

SIP element,[7] or has submitted a SIP or SIP element that does not satisfy the completeness criteria;

(2) that EPA disapproval of a SIP submission for a nonattainment area based on its failure to meet one or more elements required by the Act;

(3) a determination that the State has not made any other submission, has made an inadequate submission (as required by the Act), or that EPA disapproves such a submission; or

(4) a finding that a requirement of an approved plan is not being implemented.

Under section 110(c)(1), EPA is required to promulgate a FIP based on two types of findings:[8]

(1) a finding that a State has failed to make a required submittal or that a submittal does not satisfy the minimum completeness criteria established under section 110(k)(1)(A), or

(2) the EPA disapproval of a SIP submittal in whole or in part.

The Sanctions and FIP Clocks

Although EPA may make any of the findings discussed above to trigger the 179(a) sanctions and 110(c)(1) FIP requirements, these findings do not require the immediate imposition of sanctions or promulgation of a FIP. Instead the Act provides a "clock" for sanctions and FIP's. For plan submittals required under Part D or in response to a SIP call, section 179(a) allows

---

[7] Since EPA does not intend to issue a list of such elements per se, to ensure that such findings are consistently applied, findings of failure to submit SIP elements should be decided on a case-by-case basis in conjunction with Headquarters. The basis for the finding should be clear and well-supported.

[8] Since the deficiency is a failure to implement after a State has submitted a plan and EPA has approved it, it is unnecessary for this finding to trigger a requirement that EPA develop the required rule (i.e., prepare a FIP) and section 110(c)(1) does not require it.

for up to 18 months for the State to correct the deficiency that is the subject of a finding or disapproval before EPA is required to impose sanctions. Section 110(c)(1) provides for up to 2 years for the State to correct the deficiency and for EPA to approve a new submittal before EPA is obligated to promulgate a FIP.

The Administrator has delegated the authority to make findings of failure to submit to the RA's. The findings are made via letters from the RA's to State governors or other State officers to whom authority has been delegated. The letter itself triggers the sanctions and FIP clocks. For disapprovals, the Federal Register notice in which EPA takes final action triggers the sanctions and FIP clocks. Findings of nonimplementation have traditionally been processed as rulemaking actions through Headquarters. The sanctions clock will start when EPA makes a finding of nonimplementation in the Federal Register after soliciting comment on the proposal (the FIP clock is not triggered by such a finding). Although the findings of failure to submit and SIP disapproval start both the sanctions and FIP clocks, what is required to stop the clocks differs; therefore, they are discussed separately. Note that in some cases the sanctions clock may be stopped while EPA remains under an obligation to promulgate a FIP.

Sanctions Clock

Under section 179(a), in order to stop the sanctions clock, the State must correct the "deficiency" prompting the finding. The EPA must apply one of the two sanctions available under section 179(b) within 18 months after the date of the finding and both sanctions at 24 months, unless the deficiency has been corrected. Section 179(a) also requires EPA to apply both sanctions after 18 months if EPA finds a lack of good faith on the part of the State.

Attachment 3 provides seven scenarios illustrating how the sanctions clock operates, including examples of what constitutes a deficiency correction (and hence a stopping of the clock). In brief, for purposes of the sanctions clock, findings of failure to submit plans or complete plans are corrected when EPA finds the submittal complete[9] [although the FIP clock is still

[9] Where EPA made a finding of failure to submit and subsequently finds that the State has made a complete submittal for the plan or plan element that was the subject of the finding, the letter that makes the finding of completeness will notify the State that the sanctions clock is stopped as of the date of that

running (see FIP clock discussion)] and disapprovals are corrected when EPA takes final rulemaking action approving the plan. In addition, findings of nonimplementation are corrected when EPA makes a finding in the Federal Register that the State is now implementing that provision.

FIP Clock

Under the FIP provisions, either a SIP must be approved or a FIP must promulgated within 2 years of one of the two findings discussed above. In other words, EPA must approve the State submittal in order to stop the FIP clock. Where the sanctions and FIP clocks were started by EPA disapproval of a plan, the clocks will run concurrently. In this case, to correct the deficiency for purposes of the sanctions clock, the State must make a submittal which EPA finds approvable. Such a determination is not made until EPA issues a final approval of the plan. Final approval of a plan is also what is needed to stop the FIP clock. Attachment 3 provides seven scenarios of how the FIP clock operates.

Available Sanctions

For plan submittals required under Part D or in response to a SIP call, if the State does not correct the specific deficiency within the 18-month period allowed under section 179(a), EPA must apply at least one of the two sanctions available under section 179(b)[10] as described:

(1) Highway funding sanctions. The EPA may impose a prohibition on the approval by the Secretary of Transportation of certain projects, or the awarding of certain grants.

---

letter. The Region should periodically announce any such findings that represent corrections of failure to submit in the Federal Register.

[10] In addition, section 179(a) provides for an air pollution grant sanction that applies to grants EPA may award under section 105. However, since it is not a sanction provided under section 179(b), it is not one of the sanctions EPA must impose after the 18-month period.

(2) Offset sanctions. A ratio of at least 2-to-1 will be required for emissions reductions within the nonattainment area to offset emissions from new or modified major facilities (as required under section 173).

Regions should determine which of the sanctions will be applied at the 18- and 24-month milestones on a case-by-case basis. As discussed previously, EPA must apply both sanctions at the 18-month mark if it finds there is a lack of good faith effort. Such a determination should be made on a case-by-case basis in consultation with Headquarters. In addition, once one of the sanctions has been imposed, EPA must impose the second sanctions if the deficiency has not been corrected within 6 months (regardless of the State's efforts). Headquarters will issue a proposal of the sanctions and the Regional Office will issue the final rule imposing sanctions.

Conclusion

General comments on this memorandum should be directed to Pam Johnson of the Regional Operations Branch at (919) 541-5270. Comments related specifically to ozone or carbon monoxide should be directed to Carla Oldham at (919) 541-3347. Comments related to particulate matter, sulfur dioxide, or lead should be directed to Chris Stoneman at (919) 541-0823.

Attachment 1

Example 1

A State submits a SIP revision containing four rules: (1) control requirements for bulk gasoline plants, (2) control requirements for gasoline dispensing facilities (Stage I), (3) leak detection requirements for gasoline tanks trucks, and (4) test methods that apply to these three rules. The EPA review of the rules shows that all of the rules except the Stage I rule meet the applicable requirements of the Act. The Stage I rule fails to require submerged fill loading for all storage tanks. This is inconsistent with EPA's RACT guidance and the State has failed to propose an alternative that it has demonstrated is RACT for the applicable sources.

Partial Approval

Under the partial approval option, EPA can approve the rules for bulk terminals and tank truck leaks, approve the test methods, and disapprove the Stage I rule. These rules are separable from the Stage I rule. Disapproval of the Stage I rule does not affect the stringency of the other three rules. Therefore, the other three rules may be approved under this provision. However, the submittal as a whole would only be partially approved.

Limited Approval of Stage I Rule

Under the limited approval approach, EPA could approve the Stage I rule as being an improvement over what is currently in the SIP and, at the same time or within a reasonable time after the approval (but no later than 12 months after the submittal is complete), disapprove the rule because it does not represent RACT. The sanctions and FIP clocks would start upon the final disapproval of the rule.

Conditional Approval

Alternatively, EPA could conditionally approve the Stage I rule if the State committed to revise the rule, within 1 year of the conditional approval, to require submerged fill loading. If the State then failed to make such a revision, EPA would issue a finding converting the conditional approval to a disapproval.

Example 2

If in example 1 the first three rules (containing control requirements) are all approvable but the fourth (containing the test methods) is either deficient or has not been submitted, then the submittal would have to be handled differently. Because a test method is critical in determining the stringency of a control requirement and is needed for the requirements to be enforceable, these rules cannot be considered separable and,

therefore, partial approval would not be an option. In addition, because the control requirements will not be enforceable without a test method, it would not be appropriate to use either the limited or conditional approval approach.

Example 3

A State submits a SIP revision that contains four PM-10 rules, two for controlling emissions of fugitive dust and two for the control of residential wood combustion. The rules represent reasonable available control measures (RACM) and include (1) paving or stabilizing unpaved roads, (2) developing a traffic reduction plan for unpaved roads, (3) a mandatory episode curtailment program for residential wood combustion, and (4) encouraging changeover to new source performance standards and wood stoves. The third rule is deficient in that it does not provide a communication strategy on which the curtailment program is dependent.

Partial Approval

The EPA may approve the three rules which satisfy RACM but disapprove the episode curtailment program as failing to meet the RACM requirement. These rules are separable because disapproval of the curtailment program will not have any effect on the stringency or enforceability of the remaining rules.

Limited Approval

The EPA may approve the episode curtailment plan as strengthening the SIP by providing enforceable measures in a SIP which currently has no curtailment program. At the same time or within a reasonable time after the approval (but no later than 12 months after the submittal is complete), EPA must disapprove the rule as not representing RACM. Final disapproval of the rule would start the sanctions and FIP clocks.

Conditional Approval

The EPA may conditionally approve the rule if the State submits a commitment to submit a revised rule within 1 year of the approval. If the State then failed to make such a revision, EPA would issue a finding converting the conditional approval to a disapproval.

Attachment 2

Type of Approval	Separability	Commitment	Act Requirements	SIP Strengthening
Partial	rules must be separable	no commitment necessary	part to be approved must meet all applicable requirements	part to be approved must strengthen the SIP
Limited	deficient portion of submittal is not separable	no commitment necessary	does not have to meet <u>all</u> applicable requirements	submittal as a whole must strengthen the SIP
Conditional	deficient portion of submittal is not separable	State must commit to correct within 1 year	does not have to meet <u>all</u> applicable requirements	submittal as a whole must strengthen the SIP

Attachment 3: Sanctions and FIP Clocks Scenarios

Scenario 1: The EPA receives a SIP and finds it incomplete prior to the statutory due date of the SIP.

Although a finding that the State submitted an incomplete SIP is one of the section 179(a) findings, the sanctions and FIP clocks will not begin to run until after a submittal is due. This is because the finding must be based on the failure to submit a complete required SIP or SIP element and the submittal is not required until it is due under the statute. If a SIP submitted prior to a due date is still incomplete by the due date, then EPA will notify the State by letter that the plan remains incomplete and that the 18-month sanctions clock and the 2-year FIP clock have started.

Scenario 2: The EPA receives a SIP and finds it incomplete on or after the statutory due date of the SIP.

If EPA receives a SIP and finds it incomplete pursuant to section 110(k) on or after the statutory due date of the SIP, then, as in scenario 1, the State has failed to make a complete submittal under section 179(a). The EPA will notify the State by letter that the plan is incomplete and that the 18-month sanctions clock and the 2-year FIP clock have started.

Scenario 3: The EPA receives no submittal at the due date.

If EPA receives no submittal from a State to meet a statutory due date, then it may make a finding of failure to submit under section 179(a)(1), triggering the 18-month sanctions clock and the 2-year FIP clock.

Scenario 4: After the due date, EPA receives a SIP for which it originally made a finding of failure to submit.

Upon receiving the plan, the sanctions clock will continue to run during the completeness review and be stopped if EPA finds the plan complete and continue if EPA finds the plan incomplete. If the 18 months elapse during the time EPA is doing its completeness review, EPA will not impose sanctions unless it determines the plan incomplete. If sanctions have been imposed prior to the State's submittal, the sanctions will remain in place until EPA determines the submittal complete.

The FIP clock continues to run while EPA makes its completeness determination.

Scenario 5: The EPA originally makes a finding of failure to submit, then receives a SIP, finds it complete, but disapproves it in final rulemaking.

Upon a determination that the SIP is complete, the State corrects the deficiency that prompted the finding of nonsubmittal and the sanctions clock stops. A new sanctions clock will start upon the final SIP disapproval rulemaking. The new sanctions clock will not stop until EPA has taken final action to approve the revised SIP submittal.

Even after the submittal is determined to be complete, EPA remains under obligation to promulgate a FIP. Therefore, the disapproval of the SIP does not start a new FIP clock.

Scenario 6: The EPA originally makes a finding of failure to submit, then receives a SIP, finds it complete, and approves it in final rulemaking.

Upon a determination that the SIP is complete, the State corrects the deficiency prompting the finding of nonsubmittal and the sanctions clock stops. The EPA remains under obligation to promulgate a FIP until EPA takes final rulemaking action to approve the SIP.

Scenario 7: The EPA finds that a State has failed to implement a SIP or SIP provision.

The EPA will make a finding of nonimplementation in the Federal Register after soliciting comment on the proposal. The sanctions clock will start upon EPA taking final action and stop when EPA makes a finding in the Federal Register after notice-and-comment rulemaking that the State has corrected the deficiency that prompted the finding. A finding of nonimplementation does not start a FIP clock.

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
Office of Air Quality Planning and Standards
Research Triangle Park, North Carolina 27711

4 SEP 1992

MEMORANDUM

SUBJECT: Procedures for Processing Requests to Redesignate Areas to Attainment

FROM: John Calcagni, Director
Air Quality Management Division (MD-15)

TO: Director, Air, Pesticides and Toxics Management Division, Regions I and IV
Director, Air and Waste Management Division, Region II
Director, Air, Radiation and Toxics Division, Region III
Director, Air and Radiation Division, Region V
Director, Air, Pesticides and Toxics Division, Region VI
Director, Air and Toxics Division, Regions VII, VIII, IX, and X

Purpose

The Office of Air Quality Planning and Standards (OAQPS) expects that a number of redesignation requests will be submitted in the near future. Thus, Regions will need to have guidance on the applicable procedures for handling these requests, including maintenance plan provisions. This memorandum, therefore, consolidates the Environmental Protection Agency's (EPA's) guidance regarding the processing of requests for redesignation of nonattainment areas to attainment for ozone (O_3), carbon monoxide (CO), particulate matter (PM-10), sulfur dioxide (SO_2), nitrogen dioxide (NO_2), and lead (Pb). Regions should use this guidance as a general framework for drafting Federal Register notices pertaining to redesignation requests. Special concerns for areas seeking redesignation from unclassifiable to attainment will be addressed on a case-by-case basis.

Background

Section 107(d)(3)(E) of the Clean Air Act, as amended, states that an area can be redesignated to attainment if the following conditions are met:

1. The EPA has determined that the national ambient air quality standards (NAAQS) have been attained.

2. The applicable implementation plan has been fully approved by EPA under section 110(k).

3. The EPA has determined that the improvement in air quality is due to permanent and enforceable reductions in emissions.

4. The State has met all applicable requirements for the area under section 110 and Part D.

5. The EPA has fully approved a maintenance plan, including a contingency plan, for the area under section 175A.

Each of these criteria is discussed in more detail in the following paragraphs. Particular attention is given to maintenance plan provisions at the end of this document since maintenance plans constitute a new requirement under the amended Clean Air Act. Exceptions to the guidance will be considered on a case-by-case basis.

1. Attainment of the Standard

The State must show that the area is attaining the applicable NAAQS. There are two components involved in making this demonstration which should be considered interdependently. The first component relies upon ambient air quality data. The data that are used to demonstrate attainment should be the product of ambient monitoring that is representative of the area of highest concentration. These monitors should remain at the same location for the duration of the monitoring period required for demonstrating attainment. The data should be collected and quality-assured in accordance with 40 CFR 58 and recorded in the Aerometric Information Retrieval System (AIRS) in order for it to be available to the public for review. For purposes of redesignation, the Regional Office should verify that the integrity of the air quality monitoring network has been preserved.

For PM-10, an area may be considered attaining the NAAQS if the number of expected exceedances per year, according to 40 CFR 50.6, is less than or equal to 1.0. For O_3, the area must show that the average annual number of expected exceedances, according to 40 CFR 50.9, is less than or equal to 1.0 based on data from all monitoring sites in the area or its affected downwind environs. In making this showing, both PM-10 and O_3 must rely on 3 complete, consecutive calendar years of quality-assured air quality monitoring data, collected in accordance with 40 CFR 50, Appendices H and K. For CO, an area may be considered attaining the NAAQS if there are no violations, as determined in accordance

with 40 CFR 50.8, based on 2 complete, consecutive calendar years of quality-assured monitoring data. For SO_2, according to 40 CFR 50.4, an area must show no more than one exceedance annually and for Pb, according to section 50.12, an area may show no exceedances on a quarterly basis.

The second component relies upon supplemental EPA-approved air quality modeling. No such supplemental modeling is required for O_3 nonattainment areas seeking redesignation. Modeling may be necessary to determine the representativeness of the monitored data. For pollutants such as SO_2 and CO, a small number of monitors typically is not representative of areawide air quality or areas of highest concentration. When dealing with SO_2, Pb, PM-10 (except for a limited number of initial moderate nonattainment areas), and CO (except moderate areas with design values of 12.7 parts per million or lower at the time of passage of the Clean Air Act Amendments of 1990), dispersion modeling will generally be necessary to evaluate comprehensively sources' impacts and to determine the areas of expected high concentrations based upon current conditions. Areas which were designated nonattainment based on modeling will generally not be redesignated to attainment unless an acceptable modeling analysis indicates attainment. Regions should consult with OAQPS for further guidance addressing the need for modeling in specific circumstances.

2. State Implementation Plan (SIP) Approval

The SIP for the area must be fully approved under section 110(k),[1] and must satisfy all requirements that apply to the area. It should be noted that approval action on SIP elements and the redesignation request may occur simultaneously. An area cannot be redesignated if a required element of its plan is the subject of a disapproval; a finding of failure to submit or to implement the SIP; or partial, conditional, or limited approval. However, this does not mean that earlier issues with regard to the SIP will be reopened. Regions should not reconsider those things that have already been approved and for which the Clean Air Act Amendments did not alter what is required. In contrast, to the extent the Amendments add a requirement or alter an existing requirement so that it adds something more, Regions should consider those issues. In addition, requests from areas known to be affected by dispersion techniques which are inconsistent with EPA guidance will continue to be considered unapprovable under section 110 and will not qualify for redesignation.

---

[1]Section 110(k) contains the requirements for EPA action on plan submissions. It addresses completeness, deadlines, full and partial approval, conditional approval, and disapproval.

3. Permanent and Enforceable Improvement in Air Quality

The State must be able to reasonably attribute the improvement in air quality to emission reductions which are permanent and enforceable.[2] Attainment resulting from temporary reductions in emission rates (e.g., reduced production or shutdown due to temporary adverse economic conditions) or unusually favorable meteorology would not qualify as an air quality improvement due to permanent and enforceable emission reductions.

In making this showing, the State should estimate the percent reduction (from the year that was used to determine the design value for designation and classification) achieved from Federal measures such as the Federal Motor Vehicle Control Program and fuel volatility rules as well as control measures that have been adopted and implemented by the State. This estimate should consider emission rates, production capacities, and other related information to clearly show that the air quality improvements are the result of implemented controls. The analysis should assume that sources are operating at permitted levels (or historic peak levels) unless evidence is presented that such an assumption is unrealistic.

4. Section 110 and Part D Requirements

For the purposes of redesignation, a State must meet all requirements of section 110 and Part D that were applicable prior to submittal of the complete redesignation request. When evaluating a redesignation request, Regions should not consider whether the State has met requirements that come due under the Act after submittal of a complete redesignation request.[3]

---

[2]This is consistent with EPA's existing policy on redesignations as stated in an April 21, 1983 memorandum titled "Section 107 Designation Policy Summary." This memorandum states that in order for an area to be redesignated to attainment, the State must show that "actual enforceable emission reductions are responsible for the recent air quality improvement." This element of the policy retains its validity under the amended Act pursuant to section 193. [Note: other aspects of the April 21, 1983 memorandum have since been superseded by subsequent memorandums; interested parties should consult with OAQPS before relying on these aspects, e.g. those relating to required years of air quality data.]

[3]Under section 175A(c), however, the requirements of Part D remain in force and effect for the area until such time as it is redesignated. Upon redesignation to attainment, the requirements that became due under section 175A(c) after submittal of the complete redesignation request would no longer be applicable.

However, any requirements that came due prior to submittal of the redesignation request must be fully approved into the plan at or before the time EPA redesignates the area.

To avoid confusion concerning what requirements will be applicable for purposes of redesignation, Regions should encourage States to work closely with the appropriate Regional Office early in the process. This will help to ensure that a redesignation request submitted by the State has a high likelihood of being approved by EPA. Regions should advise States of the practical planning consequences if EPA disapproves the redesignation request or if the request is invalidated because of violations recorded during EPA's review. Under such circumstances, EPA does not have the discretion to adjust schedules for implementing SIP requirements. As a result, an area may risk sanctions and/or Federal implementation plan implementation that could result from failure to meet SIP submittal or implementation requirements.

a. Section 110 Requirements

Section 110(a)(2) contains general requirements for nonattainment plans. Most of the provisions of this section are the same as those contained in the pre-amended Act. We will provide guidance on these requirements as needed.[4]

b. Part D Requirements

Part D consists of general requirements applicable to all areas which are designated nonattainment based on a violation of the NAAQS. The general requirements are followed by a series of subparts specific to each pollutant. The general requirements appear in subpart 1. The requirements relating to O_3, CO, PM-10, SO_2, NO_2, and Pb appear in subparts 2 through 5. In those instances where an area is subject to both the general nonattainment provisions in subpart 1 as well as one of the pollutant-specific subparts, the general provisions may be subsumed within, or superseded by, the more specific requirements of subparts 2 through 5.

If an area was not classified under section 181 for O_3, or section 186 for CO, then that area is only subject to the provisions of subpart 1, "Nonattainment Areas in General." In addition to relevant provisions in subpart 1, an O_3 and CO area, which is classified, must meet all applicable requirements in subpart 2, "Additional Provisions for Ozone Nonattainment Areas," and subpart 3, "Additional Provisions for Carbon Monoxide

---

[4]General guidance regarding the requirements for SIP's may be found in the "General Preamble to Title I of the 1990 Clean Air Act Amendments," 57 FR 13498 (April 16, 1992).

Nonattainment Areas," respectively, before the area may be redesignated to attainment. All PM-10 nonattainment areas (whether classified as moderate or serious) must similarly meet the applicable general provisions of subpart 1 and the specific PM-10 provisions in subpart 4, "Additional Provisions for Particulate Matter Nonattainment Areas." Likewise, SO_2, NO_2, and Pb nonattainment areas are subject to the applicable general nonattainment provisions in subpart 1 as well as the more specific requirements in subpart 5, "Additional Provisions for Areas Designated Nonattainment for Sulfur Oxides, Nitrogen Dioxide, and Lead."

i. Section 172(c) Requirements

This section contains general requirements for nonattainment plans. A thorough discussion of these requirements may be found in the General Preamble to Title I [57 FR 13498 (April 16, 1992)]. The EPA anticipates that areas will already have met most or all of these requirements to the extent that they are not superseded by more specific Part D requirements. The requirements for reasonable further progress, identification of certain emissions increases, and other measures needed for attainment will not apply for redesignations because they only have meaning for areas not attaining the standard. The requirements for an emission inventory will be satisfied by the inventory requirements of the maintenance plan. The requirements of the Part D new source review program will be replaced by the prevention of significant deterioration (PSD) program once the area has been redesignated. However, in order to ensure that the PSD program will become fully effective immediately upon redesignation, either the State must be delegated the Federal PSD program or the State must make any needed modifications to its rules to have the approved PSD program apply to the affected area upon redesignation.

ii. Conformity

The State must work with EPA to show that its SIP provisions are consistent with section 176(c)(4) conformity requirements. The redesignation request should include conformity procedures, if the State already has these procedures in place. Additionally, we currently interpret the conformity requirement to apply to attainment areas. However, EPA has not yet issued its conformity regulations specifying what areas are subject to the conformity requirement. Therefore, if a State does not have conformity procedures in place at the time that it submits a redesignation request, the State must commit to follow EPA's conformity regulation upon issuance, as applicable. If the State submits the redesignation request subsequent to EPA's issuance of the conformity regulations, and the conformity requirement became applicable to the area prior to submission,

the State must adopt the applicable conformity requirements before EPA can redesignate the area.

5. Maintenance Plans

Section 107(d)(3)(E) of the amended Act stipulates that for an area to be redesignated, EPA must fully approve a maintenance plan which meets the requirements of section 175A. A State may submit both the redesignation request and the maintenance plan at the same time and rulemaking on both may proceed on a parallel track. Maintenance plans may, of course, be submitted and approved by EPA before a redesignation is requested. However, according to section 175A(c), pending approval of the maintenance plan and redesignation request, all applicable nonattainment area requirements shall remain in place.

Section 175A defines the general framework of a maintenance plan. The maintenance plan will constitute a SIP revision and must provide for maintenance of the relevant NAAQS in the area for at least 10 years after redesignation. Section 175A further states that the plan shall contain such additional measures, if any, as may be necessary to ensure such maintenance. Because the Act requires a demonstration of maintenance for 10 years after an area is redesignated (not 10 years after submittal of a redesignation request), the State should plan for some lead time for EPA action on the request. In other words, the maintenance demonstration should project maintenance for 10 years, beginning from a date which factors in the time necessary for EPA review and approval action on the redesignation request. In determining the amount of lead time to allow, States should consider that section 107(d)(3)(D) grants the Administrator up to 18 months from receipt of a complete submittal to process a redesignation request. The statute also requires the State to submit a revision of the SIP 8 years after the original redesignation request is approved to provide for maintenance of the NAAQS for an additional 10 years following the first 10-year period [see section 175A(b)].

In addition, the maintenance plan shall contain such contingency measures as the Administrator deems necessary to ensure prompt correction of any violation of the NAAQS [see section 175A(d)]. The Act provides that, at a minimum, the contingency measures must include a requirement that the State will implement all measures contained in the nonattainment SIP prior to redesignation. Failure to maintain the NAAQS and triggering of the contingency plan will not necessitate a revision of the SIP unless required by the Administrator, as stated in section 175A(d).

The following is a list of core provisions that we anticipate will be necessary to ensure maintenance of the relevant NAAQS in an area seeking redesignation from

nonattainment to attainment. We therefore recommend that States seeking redesignation of a nonattainment area consider these provisions. However, any final EPA determination regarding the adequacy of a maintenance plan will be made following review of the plan submittal in light of the particular circumstances facing the area proposed for redesignation and based on all relevant information available at the time.

a. Attainment Inventory

The State should develop an attainment emissions inventory to identify the level of emissions in the area which is sufficient to attain the NAAQS.[5] This inventory should be consistent with EPA's most recent guidance on emission inventories for nonattainment areas available at the time and should include the emissions during the time period associated with the monitoring data showing attainment.[6]

Source size thresholds are 100 tons/year for SO_2, NO_2, and PM-10 areas, and 5 tons/year for Pb based upon 40 CFR 51.100(k) and 51.322, as well as established practice for AIRS data. The source size threshold for serious PM-10 areas is 70 tons/year

---

[5]Where the State has made an adequate demonstration that air quality has improved as a result of the SIP (as discussed previously), the attainment inventory will generally be the actual inventory at the time the area attained the standard.

[6]The EPA's current guidance on the preparation of emission inventories for O_3 and CO nonattainment areas is contained in the following documents: "Procedures for the Preparation of Emission Inventories for Carbon Monoxide and Precursors of Ozone: Volume I" (EPA-450/4-91-016), "Procedures for the Preparation of Emission Inventories for Carbon Monoxide and Precursors of Ozone: Volume II" (EPA-450/4-91-014), "Emission Inventory Requirements for Ozone State Implementation Plans" (EPA-450/4-91-010), "Emission Inventory Requirements for Carbon Monoxide Implementation Plans" (EPA-450/4-91-011), "Guideline for Regulatory Application of the Urban Airshed Model" (EPA-450/4-91-013), "Procedures for Emission Inventory Preparation: Volume IV, Mobile Sources" (EPA-450/4-81-026d), and "Procedures for Preparing Emission Inventory Projections" (EPA-450/4-91-019). The EPA does not currently have specific guidance on attainment emissions inventories for SO_2. In lieu thereof, States are referred to the guidance on emissions data to be used as input to modeling demonstrations, contained in Table 9.1 of EPA's "Guideline on Air Quality Models (Revised)" (EPA-450/2-78-027R), July 1987, which is generally applicable to all criteria pollutants. Emission inventory procedures and requirements documents are currently being prepared by OAQPS for PM-10 and Pb; these documents are due for release by summer 1992.

according to Clean Air Act section 189(b)(3). However, the inventory should include sources below these size thresholds if these smaller sources were included in the SIP attainment demonstration. Where sources below the 100, 70, and 5 tons/year-size thresholds (e.g., areas with smaller source size definitions) are subject to a State's minor source permit program, these sources need only be addressed in the aggregate to the extent that they result in areawide growth.

For O_3 nonattainment areas, the inventory should be based on actual "typical summer day" emissions of O_3 precursors (volatile organic compounds and nitrogen oxides) during the attainment year. This will generally correspond to one of the periodic inventories required for nonattainment areas to reconcile milestones. For CO nonattainment areas, the inventory should be based on actual "typical CO season day" emissions for the attainment year. This will generally correspond to one of the periodic inventories required for nonattainment areas.

b. Maintenance Demonstration

A State may generally demonstrate maintenance of the NAAQS by either showing that future emissions of a pollutant or its precursors will not exceed the level of the attainment inventory, or by modeling to show that the future mix of sources and emission rates will not cause a violation of the NAAQS. Under the Clean Air Act, many areas are required to submit modeled attainment demonstrations to show that proposed reductions in emissions will be sufficient to attain the applicable NAAQS. For these areas, the maintenance demonstration should be based upon the same level of modeling. In areas where no such modeling was required, the State should be able to rely on the attainment inventory approach. In both instances, the demonstration should be for a period of 10 years following the redesignation.

Where modeling is relied upon to demonstrate maintenance, each plan should contain a summary of the air quality concentrations expected to result from application of the control strategy. In the process, the plan should identify and describe the dispersion model or other air quality model used to project ambient concentrations (see 40 CFR 51.46).

In either case, to satisfy the demonstration requirement the State should project emissions for the 10-year period following redesignation, either for the purpose of showing that emissions will not increase over the attainment inventory or for conducting modeling.[7] The projected inventory should consider future growth, including population and industry, should be consistent

[7]Guidance for projecting emissions may be found in the emissions inventory guidance cited in footnote 6.

with the attainment inventory, and should document data inputs and assumptions. All elements of the demonstration (e.g., emission projections, new source growth, and modeling) should be consistent with current EPA modeling guidance.[8] For O_3 and CO, the projected emissions should reflect the expected actual emissions based on enforceable emission rates and typical production rates.

For CO, a State should address the areawide component of the maintenance demonstration either by showing that future CO emissions will not increase or by conducting areawide modeling. Preferably, the State should carry out hot-spot modeling that is consistent with the Guideline on Air Quality Models (Revised), in order to demonstrate maintenance of the NAAQS. In particular, if the nonattainment problem is related to a pattern of hot-spots then hot-spot modeling should generally be conducted. However, hot-spot modeling is not automatically required. For example, if the nonattainment problem was related solely to stationary point sources, or if highway improvements have been implemented and the associated emission reductions and travel characteristics can be qualitatively documented, then hot-spot modeling is not required. In such cases, adequate documentation as well as the concurrence of Headquarters is needed.

Any assumptions concerning emission rates must reflect permanent, enforceable measures. In other words, a State generally cannot take credit in the maintenance demonstration for reductions unless there are regulations in place requiring those reductions or the reductions are otherwise shown to be permanent. Therefore, the State will be expected to maintain its implemented control strategy despite redesignation to attainment, unless such measures are shown to be unnecessary for maintenance or are replaced with measures that achieve equivalent reductions (see additional discussion under "Contingency Plan"). Emission reductions from source shutdowns can be considered permanent and enforceable to the extent that those shutdowns have been reflected in the SIP and all applicable permits have been modified accordingly.

Modeling used to demonstrate attainment may be relied upon in the maintenance demonstration where the modeling conforms to current EPA guidance and where the State has projected no significant changes in the modeling inputs during the intervening time. Where the original attainment demonstration may no longer be relied upon, States will be expected to remodel using current

---

[8]The EPA-approved modeling guidance may be found in the following documents: "Guideline on Air Quality Models (Revised)," OAQPS, RTP, NC (EPA-450/2-78-027R), July 1986; and "PM-10 SIP Development Guideline," OAQPS, RTP, NC (EPA-450/2-86-001), June 1987.

EPA referenced techniques.[9] This may be necessary where, for example, there has been a change in emissions or a change in the siting of new sources or modifications such that air quality may no longer be accurately represented by the existing modeling.

c. Monitoring Network

Once an area has been redesignated, the State should continue to operate an appropriate air quality monitoring network, in accordance with 40 CFR Part 58, to verify the attainment status of the area. The maintenance plan should contain provisions for continued operation of air quality monitors that will provide such verification. In cases where measured mobile source parameters (e.g., vehicle miles traveled congestion) have changed over time, the State may also need to perform a saturation monitoring study to determine the need for, and location of, additional permanent monitors.

d. Verification of Continued Attainment

Each State should ensure that it has the legal authority to implement and enforce all measures necessary to attain and to maintain the NAAQS. Sections 110(a)(2)(B) and (F) of the Clean Air Act, as amended, and regulations promulgated at 40 CFR 51.110(k), suggest that one such measure is the acquisition of ambient and source emission data to demonstrate attainment and maintenance.

Regardless of whether the maintenance demonstration is based on a showing that future emission inventories will not exceed the attainment inventory or on modeling, the State submittal should indicate how the State will track the progress of the maintenance plan. This is necessary due to the fact that the emission projections made for the maintenance demonstration depend on assumptions of point and area source growth.

One option for tracking the progress of the maintenance demonstration, provided here as an example, would be for the State to periodically update the emissions inventory. In this case, the maintenance plan should specify the frequency of any planned inventory updates. Such an update could be based, in part, on the annual AIRS update and could indicate new source growth and other changes from the attainment inventory (e.g., changes in vehicle miles travelled or in traffic patterns). As an alternative to a complete update of the inventory, the State may choose to do a comprehensive review of the factors that were used in developing the attainment inventory to show no significant change. If this review does show a significant change, the State should then perform an update of the inventory.

---

[9] See references for modeling guidance cited in footnote 8.

Where the demonstration is based on modeling, an option for tracking progress would be for the State to periodically (typically every 3 years) reevaluate the modeling assumptions and input data. In any event, the State should monitor the indicators for triggering contingency measures (as discussed below).

e. Contingency Plan

Section 175A of the Act also requires that a maintenance plan include contingency provisions, as necessary, to promptly correct any violation of the NAAQS that occurs after redesignation of the area. These contingency measures are distinguished from those generally required for nonattainment areas under section 172(c)(9) and those specifically required for O_3 and CO nonattainment areas under sections 182(c)(9) and 187(a)(3), respectively. For the purposes of section 175A, a State is not required to have fully adopted contingency measures that will take effect without further action by the State in order for the maintenance plan to be approved. However, the contingency plan is considered to be an enforceable part of the SIP and should ensure that the contingency measures are adopted expediently once they are triggered. The plan should clearly identify the measures to be adopted, a schedule and procedure for adoption and implementation, and a specific time limit for action by the State. As a necessary part of the plan, the State should also identify specific indicators, or triggers, which will be used to determine when the contingency measures need to be implemented.

Where the maintenance demonstration is based on the inventory, the State may, for example, identify an "action level" of emissions as the indicator. If later inventory updates show that the inventory has exceeded the action level, the State would take the necessary steps to implement the contingency measures. The indicators would allow a State to take early action to address potential violations of the NAAQS before they occur. By taking early action, States may be able to prevent any actual violations of the NAAQS and, therefore, eliminate the need on the part of EPA to redesignate an area to nonattainment.

Other indicators to consider include monitored or modeled violations of the NAAQS (due to the inadequacy of monitoring data in some situations). It is important to note that air quality data in excess of the NAAQS will not automatically necessitate a revision of the SIP where implementation of contingency measures is adequate to address the cause of the violation. The need for a SIP revision is subject to the Administrator's discretion.

The EPA will review what constitutes a contingency plan on a case-by-case basis. At a minimum, it must require that the State will implement all measures contained in the Part D nonattainment

plan for the area prior to redesignation [see section 175A(d)]. This language suggests that a State may submit a SIP revision at the time of its redesignation request to remove or reduce the stringency of control measures. Such a revision can be approved by EPA if it provides for compensating equivalent reductions. A demonstration that measures are equivalent would have to include appropriate modeling or an adequate justification. Alternatively, a State might be able to demonstrate (through EPA-approved modeling) that the measures are not necessary for maintenance of the standard. In either case, the contingency plan would have to provide for implementation of any measures that were reduced or removed after redesignation of the area.

Summary

As stated previously, this memorandum consolidates EPA's redesignation and maintenance plan guidance and Regions should rely upon it as a general framework in drafting Federal Register notices. It is strongly suggested that the Regional Offices share this document with the appropriate States. This should give the States a better understanding of what is expected from a redesignation request and maintenance plan under existing policy. Any necessary changes to existing Agency policy will be made through our action on specific redesignation requests and the review of section 175A maintenance plans for these particular areas, both of which are subject to notice and comment rulemaking procedures. Thus, in applying this memorandum to specific circumstances in a rulemaking, Regions should consider the applicability of the underlying policies to the particular facts and to comments submitted by any person. If your staff members have questions which require clarification, they may contact Sharon Reinders at (919) 541-5284 for O_3- and CO-related issues, and Eric Ginsburg at (919) 541-0877 for SO_2-, PM-10-, and Pb-related issues.

OFFICE OF
AIR QUALITY PLANNING
AND STANDARDS

MEMORANDUM

SUBJECT: Guidance on SIP Elements Required Under Sections 110(a)(1) and (2) for the 1997 8-hour Ozone and $PM_{2.5}$ National Ambient Air Quality Standards

FROM: for William T. Harnett, Director
Air Quality Policy Division (C539-01)

TO: Air Division Directors, Regions I-X

The purpose of this memorandum is to provide guidance on the "infrastructure" elements for State Implementation Plans (SIPs) required under section 110(a)(1) and (2) of the Clean Air Act (CAA) for the 1997 8-hour ozone and fine particulate matter ($PM_{2.5}$) national ambient air quality standards (NAAQS). Attachment A to this memo provides a list of the basic elements that States must include in their SIPs. To the extent that existing SIPs for ozone and particulate matter already meet these requirements, States need only certify that fact to the Environmental Protection Agency (EPA). To the extent that existing SIPs for ozone and particulate matter fail to address any of these requirements for purposes of the 1997 8-hour ozone or $PM_{2.5}$ NAAQS, States need to make timely SIP submissions to EPA to address these requirements. We anticipate that States will already have approved SIPs in place for ozone that meet the basic requirements of sections 110(a)(1) and (2). For $PM_{2.5}$, however, we anticipate that many States may need to make SIP revisions to ensure that their existing SIPs for prior particulate matter NAAQS are revised to include the new particle size indicator.

Background

On July 18, 1997, the EPA promulgated new and revised NAAQS for ozone and particulate matter. For ozone, EPA revised the NAAQS to provide an 8-hour averaging period (versus a 1-hour averaging period for the pre-existing NAAQS), and set the level of the standard at 0.08 ppm (versus 0.12 ppm for the pre-existing NAAQS). For PM, EPA promulgated a new 24-hour and a new

annual NAAQS for $PM_{2.5}$ (particles with an aerodynamic diameter less than or equal to a nominal 2.5 micrometers).[1]

Under sections 110(a)(1) and (2) of the CAA, all States are required to submit plans to provide for the implementation, maintenance, and enforcement of the 8-hour ozone and $PM_{2.5}$ standards. Sections 110(a)(1) and (2) require States to address basic SIP requirements, including emissions inventories, monitoring, and modeling to assure attainment and maintenance of the standards. By statute, SIPs meeting the requirements of sections 110(a)(1) and (2) are to be submitted by States within 3 years after promulgation of a new or revised standard. This being the case, States were required to submit such SIPs for the 1997 standards to EPA no later than July 2000. However, intervening litigation over the 1997 8-hour ozone and $PM_{2.5}$ NAAQS, created uncertainty about how to proceed and, to date, States have not submitted SIPs to meet the basic or infrastructure requirements enumerated in sections 110(a)(1) and (2).

In March of 2004, Earth Justice initiated a lawsuit against EPA for failure to take action against States that had not made SIP submissions to meet the requirements of sections 110(a)(1) and (2), i.e., failure to make a "finding of failure to submit." On March 10, 2005, EPA entered into a Consent Decree with Earth Justice that obligates EPA to make official findings whether States have made required SIP submissions by dates certain. The Consent Decree obligates EPA to determine whether States have made SIP submissions required to meet CAA section 110(a)(2)(D)(i) relating to interstate transport by no later than March 15, 2005. The Consent Decree also obligates EPA to make a determination whether States have made submissions necessary to meet the remaining 110(a)(1) and (2) requirements by December 15, 2007, for the 8-hour ozone NAAQS, and by October 5, 2008, for the $PM_{2.5}$ NAAQS.[2] It should be noted that the latter determinations pertain only to whether the submissions are complete, pursuant to section 110(k)(1)(A), and do not constitute EPA approval or disapproval of such submissions. In addition, the determinations required by the Consent Decree explicitly exclude any determinations regarding: (i)

---

[1] More recently, on December 18, 2006, EPA again revised the standards for particulate matter, tightening the 24-hour $PM_{2.5}$ standard from 65 micrograms per cubic meter ($\mu g/m^3$) to 35 $\mu g/m,^3$ and retaining the current annual fine particle standard at 15 $\mu g/m^3$. EPA also decided to retain the existing 24-hour PM_{10} standard of 150 $\mu g/m^3$ and to revoke the annual PM_{10}. This guidance document applies only to the SIP submission requirements for the 1997 8-hour Ozone and $PM_{2.5}$ NAAQS. EPA will address SIP requirements for the 2006 NAAQS separately, although the Agency notes that the statutory requirements for SIPs for new or revised NAAQS are comparable.

[2] The dates specified in the Consent Decree reflect the anticipated dates for submission of nonattainment area SIPs for each NAAQS, plus six months for EPA evaluation. EPA presumed that States would make SIP submissions meeting the basic requirements of sections 110(a)(1) and (2) for each NAAQS contemporaneously with, or not later than, SIPs meeting the nonattainment area plan requirements. EPA notes that recent decisions by the U.S. Court of Appeals for the District of Columbia concerning the implementation rule for the 8-hour Ozone NAAQS have affected certain nonattainment area SIP requirements. These judicial decisions do not, however, affect States' obligations under the CAA or EPA's obligations under the Consent Decree concerning the infrastructure SIP requirements of sections 110(a)(1) and (2).

submissions required by section 110(a)(2)(C) to the extent that subsection pertains to a nonattainment area new source permit program in part D Title I of the CAA; and (ii) submissions required by section 110(a)(2)(I) for Part D Title I nonattainment area plans.

In accordance with the Consent Decree, EPA has already published a finding that all States had failed to submit new SIPs addressing interstate transport for the 8-hour ozone and $PM_{2.5}$ NAAQS, as required by section 110(a)(2)(D)(i) of the CAA (70 FR 21147, April 25, 2005). That finding initiated a 2-year deadline for the promulgation of a Federal Implementation Plan (FIP) by EPA for each such State unless, prior to that time, each State makes a submission to meet the requirements of Section 110(a)(2)(D)(i) and EPA approves such submission. On May 12, 2005, EPA published the Clean Air Interstate Rule (CAIR) which identifies the degree to which emissions of SO_2 and NO_x in certain States significantly contribute to nonattainment of, or interfere with maintenance of, the 1997 8-hour ozone and $PM_{2.5}$ NAAQS in downwind States, and the reductions that must be achieved in those States to eliminate such contributions.

On August 15, 2006, EPA issued guidance entitled "Guidance for State Implementation Plan (SIP) Submissions to Meet Current Outstanding Obligations Under Section 110(a)(2)(D)(i) for the 8-hour Ozone and $PM_{2.5}$ National Ambient Air Quality Standards." The section 110(a)(2)(D)(i) guidance indicates that States within the CAIR region can satisfy 110(a)(2)(D) by satisfying the requirements of the CAIR, and addresses what other States that are outside of the CAIR region should consider doing to meet the "significant contribution" and "interfere with maintenance" requirements of section 110(a)(2)(D)(i) for the 1997 standards. The section 110(a)(2)(D)(i) guidance also addresses what all States (whether inside or outside of the CAIR region) should consider in making SIP submissions to meet the "prevention of significant deterioration" and "protect visibility" requirements of section 110(a)(2)(D)(i). The SIP submissions addressed by the section 110(a)(2)(D)(i) guidance are those that are necessary to rectify the finding of failure to submit that EPA has already issued for all States for section 110(a)(2)(D)(i).

The guidance contained in this memorandum is intended as a reminder that States must have SIPs for the 1997 8-hour ozone and $PM_{2.5}$ NAAQS that meet all of the requirements of sections 110(a)(1) and (2). Pursuant to the Consent Decree, EPA has an obligation to take action to determine whether States have made such submissions by the dates noted above. Because States should currently be in the process of submitting nonattainment SIPs for the 8-hour ozone standard and working on nonattainment area SIPs for the $PM_{2.5}$ standard, we want to alert them to be sure that their SIPs also meet the basic requirements of sections 110(a)(1) and (2).

Guidance

The EPA believes that the currently-approved section 110 SIPs for ozone may already be adequate in most cases to implement the 8-hour ozone NAAQS. Many of the required section 110(a)(1) and (2) SIP elements relate to the general information and authorities that constitute the "infrastructure" of the ozone air quality management program, and these have been in place since the initial SIPs were submitted in response to the 1970 Clean Air Act. For particulate matter, however, EPA believes that some States may need to adopt language specific to the $PM_{2.5}$ NAAQS to ensure that they have adequate SIP provisions to implement the $PM_{2.5}$ NAAQS, e.g., existing State laws may refer to PM_{10} specifically or to particulate matter more generally, rather than to $PM_{2.5}$. We believe that with one exception, the infrastructure requirements of sections 110(a)(1) and (2) are relatively self explanatory, and past experience with SIPs for other NAAQS should enable States to meet these requirements with assistance from EPA Regions. The one exception is section 110(a)(2)(G) relating to emergency episodes, for which EPA intends to take additional regulatory action to provide necessary numerical limits and concentration levels for emergency episode action plans for $PM_{2.5}$.

States should review and revise, as appropriate, their existing ozone and particulate matter SIPs to ensure that they are adequate to address the 8-hour ozone and $PM_{2.5}$ NAAQS. If a State determines that its existing SIP is adequate, then the State needs to certify, via a letter to the Agency from the Governor or his/her designee, that the existing SIPs contain provisions that address the requirements for the 8-hour ozone and $PM_{2.5}$ NAAQS. If a State determines that its existing ozone or particulate matter SIPs are inadequate, however, then the State needs to submit a SIP revision to make the appropriate changes.

With respect to $PM_{2.5}$, States may find it more advantageous to revise the language in their SIPs to identify "particulate matter" as the pollutant being implemented and define the size fractions as "those that EPA has currently set for the NAAQS" to the extent such an approach would be authorized by State law. This will ensure that the provisions remain adequate in the event that future changes occur to the particulate matter standards. States could also specify both PM_{10} and $PM_{2.5}$ as the size fractions if a State prefers to be more specific.

As an aid to the States in addressing the $PM_{2.5}$ related requirements of Section 110(a)(2)(G) pertaining to emergency episode provisions, EPA intends to take action to revise 40 CFR, Part 51, subpart H (sections 51.150). The rule changes will establish the priority classifications which determine the emergency episode plan requirements for each area and establish a significant harm level (SHL) for $PM_{2.5}$. Until these changes are final, EPA recommends that States rely on relevant information contained in upcoming EPA rule proposals or other EPA-issued interim guidance to satisfy the section 110(a)(2)(G) requirements for $PM_{2.5}$. After EPA issues final rules, EPA will work with States to revise SIP

submissions that were based on interim information, as appropriate. States may wish to take advantage of the parallel processing mechanism for making their section 110(a)(2)(G) submittal in the interim while EPA completes rulemakings on the SHL and the emergency episode plan requirements under 40 CFR 51.150.

The SHL for the 8-hour ozone NAAQS will remain unchanged as 0.60 ppm ozone, 2-hr average, as indicated in 40 CFR Part 51.151. EPA believes that the existing ozone-related provisions of 40 CFR Subpart H remain appropriate. Therefore, EPA expects that for purposes of the 1997 8-hour ozone NAAQS, States need only to confirm that they have existing emergency episode plan provisions consistent with EPA's existing regulatory requirements.

By statute, States are required to make SIP submissions to meet the basic requirements of CAA sections 110(a)(1) and (2) within 3 years after promulgation of any new or revised standards. For the 1997 8-hour ozone and $PM_{2.5}$ standards, this deadline was July 2000. By Consent Decree, as noted above, EPA has agreed to make a determination whether or not States have submitted SIPs to meet these requirements by a date certain. In the case of 8-hour ozone SIPs, this date is December 15, 2007. For $PM_{2.5}$ SIPs, this date is October 15, 2008. In order for EPA to evaluate the submissions adequately, EPA requests that States make their certifications of SIP adequacy or SIP revisions as soon as possible and to the extent feasible sufficiently in advance of these dates to allow EPA time to determine whether complete submissions have been made.

If you have any questions concerning this guidance, please contact Mr. David Sanders at (919) 541-3356. Please ensure that the appropriate air agency officials for States in your Region are made aware of this guidance.

Attachment A: Required Section 110 SIP Elements

The SIP elements listed below are required under section 110(a)(1) and (2). Section 110(a)(1) provides the procedural and timing requirements for SIPs. Section 110(a)(2) lists the basic or "infrastructure" elements that all SIPs must contain. We note that this list is not intended to constitute an interpretation of these provisions, or a change of past practice with respect to these provisions, merely a brief description of the required SIP elements.

Emission limits and other control measures: Section 110(a)(2)(A) requires SIPs to include enforceable emission limits and other control measures, means or techniques, schedules for compliance and other related matters. EPA notes that the specific nonattainment area plan requirements of section 110(a)(2)(I) are subject to the timing requirement of section 172, not the timing requirement of section 110(a)(1), and also that SIPs to meet this section are not covered by the Consent Decree.

Ambient air quality monitoring/data system: Section 110(a)(2)(B) requires SIPs to include provisions to provide for establishment and operation of ambient air quality monitors, collecting and analyzing ambient air quality data, and making these data available to EPA upon request.

Program for enforcement of control measures: Section 110(a)(2)(C) requires States to include a program providing for enforcement of all SIP measures and the regulation of construction of new or modified stationary sources to meet prevention of significant deterioration (PSD) and nonattainment NSR requirements.

Interstate transport: Section 110(a)(2)(D) requires SIPs to include provisions prohibiting any source or other type of emissions activity in one State from contributing significantly to nonattainment, or interfering with maintenance, of the NAAQs in another State, or from interfering with measures required to prevent significant deterioration of air quality or to protect visibility in another State. EPA has already issued CAIR to assist States in developing SIPs to meet this requirement for purposes of the 8-hour Ozone and $PM_{2.5}$ NAAQS, and has issued separate guidance to all States on how to comply with each prong of this statutory provision.

Adequate resources: Section 110(a)(2)(E) requires States to provide for adequate personnel, funding, and legal authority under State law to carry out its SIP, and related issues.

Stationary source monitoring system: Section 110(a)(2)(F) requires States to establish a system to monitor emissions from stationary sources and to submit

periodic emissions reports.

Emergency power: Section 110(a)(2)(G) requires States to provide for authority to address activities causing imminent and substantial endangerment to public health, including contingency plans to implement the emergency episode provisions in their SIPs.

Future SIP revisions: Section 110(a)(2)(H) requires States to have the authority to revise their SIPs in response to changes in the NAAQS, availability of improved methods for attaining the NAAQS, or in response to an EPA finding that the SIP is substantially inadequate.

Consultation with government officials: Section 110(a)(2)(J) requires States to provide a process for consultation with local governments and Federal Land Managers carrying out NAAQS implementation requirements pursuant to section 121 relating to consultation.

Public notification: Section 110(a)(2)(J) further requires States to notify the public if NAAQS are exceeded in an area and to enhance public awareness of measures that can be taken to prevent exceedances.

PSD and visibility protection: Section 110(a)(2)(J) also requires States to meet applicable requirements of part C related to prevention of significant deterioration and visibility protection.

Air quality modeling/data: Section 110(a)(2)(K) requires that SIPs provide for performing air quality modeling for predicting effects on air quality of emissions from any NAAQS pollutant and submission of such data to EPA upon request.

Permitting fees: Section 110(a)(2)(L) requires SIPs to require each major stationary source to pay permitting fees to cover the cost of reviewing, approving, implementing and enforcing a permit.

Consultation/participation by affected local entities: Section 110(a)(2)(M) requires States to provide for consultation and participation in SIP development by local political subdivisions affected by the SIP.

National Ambient Air Quality Standards for Particulate Matter; Final Rule

ENVIRONMENTAL PROTECTION AGENCY

40 CFR Part 50

[AD–FRL–5725–2]

RIN 2060–AE66

National Ambient Air Quality Standards for Particulate Matter

AGENCY: Environmental Protection Agency (EPA).

ACTION: Final rule.

SUMMARY: This document describes EPA's decision to revise the national ambient air quality standards (NAAQS) for particulate matter (PM) based on its review of the available scientific evidence linking exposures to ambient PM to adverse health and welfare effects at levels allowed by the current PM standards. The current primary PM standards are revised in several respects: Two new $PM_{2.5}$ standards are added, set at 15 μg/m^3, based on the 3-year average of annual arithmetic mean $PM_{2.5}$ concentrations from single or multiple community-oriented monitors, and 65 μg/m^3, based on the 3-year average of the 98th percentile of 24-hour $PM_{2.5}$ concentrations at each population-oriented monitor within an area; and the current 24-hour PM_{10} standard is revised to be based on the 99th percentile of 24-hour PM_{10} concentrations at each monitor within an area. The new suite of primary standards will provide increased protection against a wide range of PM-related health effects, including premature mortality and increased hospital admissions and emergency room visits, primarily in the elderly and individuals with cardiopulmonary disease; increased respiratory symptoms and disease, in children and individuals with cardiopulmonary disease such as asthma; decreased lung function, particularly in children and individuals with asthma; and alterations in lung tissue and structure and in respiratory tract defense mechanisms. The current secondary standards are revised by making them identical in all respects to the new suite of primary standards. The new secondary standards, in conjunction with a regional haze program, will provide appropriate protection against PM-related public welfare effects including soiling, material damage, and visibility impairment. In conjunction with the new $PM_{2.5}$ standards, a new reference method has been specified for monitoring PM as $PM_{2.5}$.

EFFECTIVE DATE: This action is effective September 16, 1997.

ADDRESSES: A docket containing information relating to the EPA's review of the PM primary and secondary standards (Docket No. A–95–54) is available for public inspection in the Central Docket Section of the U.S. Environmental Protection Agency, South Conference Center, Rm. 4, 401 M St., SW., Washington, DC. This docket incorporates the docket established for the air quality Criteria Document (Docket No. ECAO–CD–92–0671). The docket may be inspected between 8 a.m. and 3 p.m., Monday through Friday, except legal holidays, and a reasonable fee may be charged for copying. The information in the docket constitutes the complete basis for the decision announced in this document. For the availability of related information, see ''SUPPLEMENTARY INFORMATION.''

FOR FURTHER INFORMATION CONTACT: John H. Haines, MD–15, Air Quality Strategies and Standards Division, Office of Air Quality Planning and Standards, U.S. Environmental Protection Agency, Research Triangle Park, NC 27711; telephone: (919) 541–5533; e-mail: haines.john@epamail.epa.gov.

SUPPLEMENTARY INFORMATION:

Related Final Rules on PM Monitoring

In a separate document published elsewhere in this issue of the **Federal Register**, EPA is amending its ambient air quality surveillance requirements (40 CFR part 58) and its ambient air monitoring reference and equivalent methods (40 CFR part 53) for PM.

Availability of Related Information

Certain documents are available from the U.S. Department of Commerce, National Technical Information Service, 5285 Port Royal Road, Springfield, VA 22161. Available documents include:

(1) Air Quality Criteria for Particulate Matter (Criteria Document) (three volumes, EPA/600/P–95–001aF thru EPA/600/P–95–001cF, April 1996, NTIS #PB–96–168224, $234.00 paper copy).

(2) Review of the National Ambient Air Quality Standards for Particulate Matter: Policy Assessment of Scientific and Technical Information (Staff Paper) (EPA–452/R–96–013, July 1996, NTIS #PB–97–115406, $47.00 paper copy and $19.50 microfiche). (Add a $3.00 handling charge per order.)

A limited number of copies of other documents generated in connection with this standard review, such as technical support documents pertaining to air quality, monitoring, and health risk assessment, can be obtained from: Environmental Protection Agency Library (MD–35), Research Triangle Park, NC 27711, telephone (919) 541–2777. These and other related documents are also available for inspection and copying in the EPA docket at the address under ''ADDRESSES,'' at the beginning of this document.

Electronic Availability

The Staff Paper and human health risk assessment support documents are available on the Agency's Office of Air Quality Planning and Standards' (OAQPS) Technology Transfer Network (TTN) Bulletin Board System (BBS) in the Clean Air Act Amendments area, under Title I, Policy/Guidance Documents. To access the bulletin board, a modem and communications software are necessary. To dial up, set your communications software to 8 data bits, no parity and one stop bit. Dial (919) 541–5742 and follow the on-screen instructions to register for access. After registering, proceed to choice ''<T> Gateway to TTN Technical Areas'', then choose ''<E> CAAA BBS''. From the main menu, choose ''<1> Title I: Attain/Maint of NAAQS'', then ''<P> Policy Guidance Documents.'' To access these documents through the World Wide Web, click on ''TTN BBSWeb'', then proceed to the Gateway to TTN Technical areas, as above. If assistance is needed in accessing the system, call the help desk at (919) 541–5384 in Research Triangle Park, NC.

Implementation Strategy For Revised Air Quality Standards

On Wednesday, July 16, 1997, President Clinton signed a memorandum to the Administrator specifying his goals for the implementation of the O_3 and PM standards. Attached to the President's memorandum is a strategy prepared by an interagency Administration group outlining the next steps that would be necessary for implementing these standards. The EPA will prepare guidance and proposed rules consistent with the President's memorandum. Copies of the Presidential document are available in paper copy by contacting the U.S. Environmental Protection Agency Library at the address under ''Availability of Related Information'' and in electronic form as discussed above in ''Electronic Availability.''

The following topics are discussed in this preamble:

I. Background

A. Legislative Requirements

Two sections of the Clean Air Act (Act) govern the establishment, review, and revision of NAAQS. Section 108 of the Act (42 U.S.C. 7408) directs the Administrator to identify certain pollutants which ''may reasonably be anticipated to endanger public health and welfare'' and to issue air quality criteria for them. These air quality criteria are to ''accurately reflect the latest scientific knowledge useful in indicating the kind and extent of all identifiable effects on public health or welfare which may be expected from the presence of [a] pollutant in the ambient air * * *.''

Section 109 of the Act (42 U.S.C. 7409) directs the Administrator to propose and promulgate ''primary'' and ''secondary'' NAAQS for pollutants identified under section 108 of the Act. Section 109(b)(1) of the Act defines a primary standard as one ''the attainment and maintenance of which in the judgment of the Administrator, based on [the] criteria and allowing an adequate margin of safety, are requisite to protect the public health.'' The margin of safety requirement was intended to address uncertainties associated with inconclusive scientific and technical information available at the time of standard setting, as well as to provide a reasonable degree of protection against hazards that research has not yet identified. Both kinds of uncertainties are components of the risk associated with pollution at levels below those at which human health effects can be said to occur with reasonable scientific certainty. Thus, by selecting primary standards that provide an adequate margin of safety, the Administrator is seeking not only to prevent pollution levels that have been demonstrated to be harmful but also to prevent lower pollutant levels that she finds may pose an unacceptable risk of harm, even if the risk is not precisely identified as to nature or degree. The Act does not require the Administrator to establish a primary NAAQS at a zero-risk level, but rather at a level that reduces risk sufficiently so as to protect public health with an adequate margin of safety. The selection of any particular approach to providing an adequate margin of safety is a policy choice left specifically to the Administrator's judgment. *Lead Industries Ass'n* v. *EPA*, 647 F.2d 1130, 1161–1162 (D.C. Cir.1980).

A secondary standard, as defined in section 109 (b)(2) of the Act, must ''specify a level of air quality the attainment and maintenance of which in the judgment of the Administrator, based on [the] criteria, [are] requisite to protect the public welfare from any known or anticipated adverse effects associated with the presence of [the] pollutant in the ambient air.'' Welfare effects as defined in section 302(h) of the Act (42 U.S.C. 7602(h)) include, but are not limited to, ''effects on soils, water, crops, vegetation, manmade materials, animals, wildlife, weather, visibility, and climate, damage to and deterioration of property, and hazards to transportation, as well as effects on economic values and on personal comfort and well-being.''

Section 109(d)(1) of the Act requires periodic review and, if appropriate, revision of existing air quality criteria and NAAQS. Section 109(d)(2) of the Act requires appointment of an independent scientific review committee to review criteria and standards and recommend new standards or revisions of existing criteria and standards, as appropriate. The committee established under section 109(d)(2) of the Act is known as the Clean Air Scientific Advisory Committee (CASAC), a standing committee of EPA's Science Advisory Board.

B. Related Control Requirements

States are primarily responsible for ensuring attainment and maintenance of ambient air quality standards once EPA has established them. Under section 110 of the Act (42 U.S.C. 7410) and related provisions, States are to submit, for EPA approval, State implementation plans (SIP's) that provide for the attainment and maintenance of such standards through control programs directed to sources of the pollutants involved. The States, in conjunction with EPA, also administer the prevention of significant deterioration program (42 U.S.C. 7470–7479) for these pollutants. In addition, Federal programs provide for nationwide reductions in emissions of these and other air pollutants through the Federal Motor Vehicle Control Program under Title II of the Act (42 U.S.C. 7521–7574), which involves controls for automobile, truck, bus, motorcycle, nonroad engine, and aircraft emissions; the new source performance standards under section 111 of the Act (42 U.S.C. 7411); and the national emission standards for hazardous air pollutants under section 112 of the Act (42 U.S.C. 7412).

C. Review of Air Quality Criteria and Standards for PM

Particulate matter is the generic term for a broad class of chemically and physically diverse substances that exist as discrete particles (liquid droplets or solids) over a wide range of sizes. Particles originate from a variety of anthropogenic stationary and mobile sources as well as from natural sources. Particles may be emitted directly or formed in the atmosphere by transformations of gaseous emissions such as sulfur oxides (SO_x), nitrogen oxides (NO_x), and volatile organic compounds (VOC). The chemical and physical properties of PM vary greatly with time, region, meteorology, and source category, thus complicating the assessment of health and welfare effects.

The last review of PM air quality criteria and standards was completed in July 1987 with notice of a final decision to revise the existing standards published in the **Federal Register** (52 FR 24854, July 1, 1987). In that decision, EPA changed the indicator for PM from total suspended particles (TSP) to

PM_{10}.[1] Identical primary and secondary PM_{10} standards were set for two averaging times: 50 μg/m³, expected annual arithmetic mean, averaged over 3 years, and 150 μg/m³, 24-hour average, with no more than one expected exceedance per year.[2]

The EPA initiated this current review of the air quality criteria and standards for PM in April 1994 by announcing its intention to develop a revised Air Quality Criteria Document for Particulate Matter (henceforth, the ''Criteria Document''). Thereafter, the EPA presented its plans for review of the criteria and standards for PM under a highly accelerated, court-ordered schedule[3] at a public meeting of the CASAC in December 1994. Several workshops were held by EPA's National Center for Environmental Assessment (NCEA) to discuss important new health effects information in November 1994 and January 1995. External review drafts of the Criteria Document were made available for public comment and were reviewed by CASAC at public meetings held in August and December 1995 and February 1996. The CASAC came to closure in its review of the Criteria Document, advising the Administrator in a March 15, 1996 closure letter (Wolff, 1996a) that ''although our understanding of the health effects of PM is far from complete, a revised Criteria Document which incorporates the Panel's latest comments will provide an adequate review of the available scientific data and relevant studies of PM.'' CASAC and public comments from these meetings, and from subsequent written comments and the closure letter, were incorporated as appropriate in the final Criteria Document (U.S. EPA, 1996a).

External review drafts of a Staff Paper prepared by the Office of Air Quality Planning and Standards (OAQPS), Review of the National Ambient Air Quality Standards for Particulate Matter: Assessment of Scientific and Technical Information (henceforth, the ''Staff Paper''), were made available for public comment and were reviewed by CASAC at public meetings in December 1995 and May 1996.[4] The CASAC came to closure in its review of the Staff Paper, advising the Administrator in a June 13, 1996 closure letter (Wolff, 1996b) that ''the Staff Paper, when revised, will provide an adequate summary of our present understanding of the scientific basis for making regulatory decisions concerning PM standards.'' CASAC and public comments from these meetings, subsequent written comments, and the CASAC closure letter were incorporated as appropriate in the final Staff Paper (U.S. EPA, 1996b).

On November 27, 1996, EPA announced its proposed decision to revise the NAAQS for PM (61 FR 65638, December 13, 1996) (hereafter ''proposal'') as well as its proposed decision to revise the NAAQS for ozone (O_3)(61 FR 65716, December 13, 1996). In the proposal, EPA identified proposed revisions, based on the air quality criteria for PM, and solicited public comments on alternative primary standards and on the proposed forms of the standards.

To ensure the broadest possible public input on the PM and O_3 proposals, EPA took extensive and unprecedented steps to facilitate the public comment process beyond the normal process of providing an opportunity to request a hearing and receiving written comments submitted to the rulemaking docket. The EPA established a national toll-free telephone hotline to facilitate public comments on the proposed revisions to the PM and O_3 NAAQS, and on related notices dealing with the implementation of revised PM and O_3 standards, as well as a system for the public to submit comments on the proposals electronically via the Internet. Over 14,000 calls and over 4,000 electronic mail messages were received through these channels. The public could also access key supporting documents (including the Criteria Document, Staff Paper, related technical documents and fact sheets) via the Internet.

The EPA also held several public hearings and meetings across the country to provide direct opportunities for public comment on the proposed revisions to the PM and O_3 NAAQS and to disseminate information to the public about the proposed standard revisions. On January 14 and 15, 1997, EPA held concurrent, 2-day public hearings in Boston, MA, Chicago, IL, and Salt Lake City, UT. A fourth public hearing, which focused primarily on PM monitoring issues, was held in Durham, NC on January 14, 1997. Over 400 citizens and organizations testified during these public hearings. EPA also held two national satellite telecasts to answer questions on the standards and participated in meetings sponsored by the Air and Waste Management Association on the proposed revisions to the standards at more than 10 locations across the country. Beyond that, several EPA regional offices held public meetings and workshops and participated in hearings that States and cities held around the country.

As a result of this intensive effort to solicit public input, over 50,000 written and oral comments were received on the proposed revisions to the PM NAAQS by the close of the public comment period on March 12, 1997. Major issues raised in the comments are discussed throughout the preamble of this final decision. A comprehensive summary of all significant comments, along with EPA's response to such comments (hereafter ''Response to Comments''), can be found in the docket for this rulemaking (Docket No. A–95–54).

The principal focus of this current review of the air quality criteria and standards for PM is on recent epidemiological evidence reporting associations between ambient concentrations of PM and a range of serious health effects. Particular attention has been given to several size-specific classes of particles, including PM_{10} and the principal fractions of PM_{10}, referred to as the fine ($PM_{2.5}$)[5] and coarse ($PM_{10-2.5}$)[6] fractions. As discussed in the Criteria Document, fine and coarse fraction particles can be differentiated by their sources and formation processes and their chemical and physical properties, including behavior in the atmosphere. Detailed discussions of atmospheric formation, ambient concentrations, and health and welfare effects of PM, as well as quantitative estimates of human health risks associated with exposure to PM, can be found in the Criteria Document and in the Staff Paper.

[1] PM_{10} refers to particles with an aerodynamic diameter less than or equal to a nominal 10 micrometers. Technical details further specifying the measurement of PM_{10} are contained in 40 CFR part 50, Appendices J and M.

[2] A more complete history of the PM NAAQS is presented in section II.B of the OAQPS Staff Paper, Review of National Ambient Air Quality Standards for Particulate Matter: Assessment of Scientific and Technical Information (U.S. EPA, 1996b).

[3] A court order entered in *American Lung Association* v. *Browner*, CIV–93–643–TUC–ACM (D. Ariz.,October 6, 1994), as subsequently modified, requires publication of EPA's final decision on the review of the PM NAAQS by July 19, 1997.

[4] The Staff Paper evaluates policy implications of the key studies and scientific information in the Criteria Document, identifies critical elements that EPA staff believes should be considered, and presents staff conclusions and recommendations of suggested options for the Administrator's consideration.

[5] $PM_{2.5}$ refers to particles with an aerodynamic diameter less than or equal to a nominal 2.5 micrometers, as further specified in 40 CFR part 50, Appendix L in this document.

[6] $PM_{10-2.5}$ refers to those particles with an aerodynamic diameter less than or equal to a nominal 10 micrometers but greater than 2.5 micrometers. In other words, it refers to the inhalable particles that remain if fine ($PM_{2.5}$) particles are removed from a sample of PM_{10} particles.

D. Summary of Proposed Revisions to the PM Standards

For reasons discussed in the proposal, the Administrator proposed to revise the current primary standards for PM (as indicated by PM_{10}), by adding two new primary $PM_{2.5}$ standards set at 15 μg/m^3, annual mean, and 50 μg/m^3, 24-hour average. The proposed annual $PM_{2.5}$ standard would be based on the 3-year average of the annual arithmetic mean $PM_{2.5}$ concentrations, spatially averaged across an area. The proposed 24-hour $PM_{2.5}$ standard would be based on the 3-year average of the 98th percentile of 24-hour $PM_{2.5}$ concentrations at each population-oriented monitor within an area. The proposal solicited comment on two alternative approaches for selecting the levels of $PM_{2.5}$ standards. The Administrator also proposed to revise the current 24-hour primary PM_{10} standard of 150 μg/m^3 by replacing the 1-expected-exceedance form with a 98th percentile form, averaged over 3 years at each monitor within an area, solicited comment on an alternative proposal to revoke the 24-hour PM_{10} standard, and proposed to retain the current annual primary PM_{10} standard of 50 μg/m^3. The proposal also solicited comment on proposed revisions to 40 CFR part 50, Appendix K to establish new data handling conventions for calculating 98th percentile values and spatial averages, revisions to 40 CFR part 50, Appendix J to modify the reference method for monitoring PM as PM_{10}, and a proposed new reference method for monitoring PM as $PM_{2.5}$ (40 CFR part 50, Appendix L).

With regard to the secondary standards, the Administrator proposed to revise the current secondary standards by making them identical to the suite of proposed primary standards, in conjunction with the establishment of a regional haze program under section 169A of the Act.

II. Rationale for the Primary Standards

A. Introduction

1. *Overview.* This document presents the Administrator's final decisions regarding the need to revise the current primary ambient air quality standards for PM, and, more specifically, regarding the establishment of new annual and 24-hour $PM_{2.5}$ primary standards and revisions to the form of the current 24-hour PM_{10} primary NAAQS. These decisions are based on a thorough review, in the Criteria Document, of the latest scientific information on known and potential human health effects associated with exposure to PM at levels typically found in the ambient air. These decisions also take into account:

(1) Staff Paper assessments of the most policy-relevant information in the Criteria Document, upon which staff recommendations for new and revised primary standards are based.

(2) CASAC advice and recommendations, as reflected in discussions of drafts of the Criteria Document and Staff Paper at public meetings, in separate written comments, and in the CASAC's closure letters to the Administrator.

(3) Public comments received during the development of these documents, either in connection with CASAC meetings or separately.

(4) Extensive public comments received on the proposed decisions regarding the primary PM standards.

After taking this information and comments into account, and for the reasons discussed below in this unit, the Administrator concludes that revisions to the current primary standards to provide increased public health protection against a variety of health risks are appropriate. More specifically, the Administrator has determined that it is appropriate to establish new annual and 24-hour $PM_{2.5}$ standards, to revise the current 24-hour PM_{10} standard, and to retain the current annual PM_{10} standard. As discussed more fully below in this unit, the rationale for the final decisions regarding the PM primary NAAQS includes consideration of:

(1) Health effects information, and alternative views on the appropriate interpretation and use of the information, as the basis for judgments about the risks to public health presented by population exposures to ambient PM.

(2) Insights gained from a quantitative risk assessment conducted to provide a broader perspective for judgments about protecting public health from the risks associated with PM exposures.

(3) Specific conclusions regarding the need for revisions to the current standards and the elements of PM standards (i.e., indicator, averaging time, form, and level) that, taken together, would be appropriate to protect public health with an adequate margin of safety.

As with virtually any policy-relevant scientific research, there is uncertainty in the characterization of health effects attributable to exposure to ambient PM. As discussed in the proposal, however, there is now a greatly expanded body of health effects information as compared with that available during the last review of the PM standards. Moreover, the recent evidence on PM-related health effects has undergone an unusually high degree of scrutiny and reanalysis over the past several years, beginning with a series of workshops held early in the review process to discuss important new information. A number of opportunities were provided for public comment on successive drafts of the Criteria Document and Staff Paper, as well as for intensive peer review of these documents by CASAC at several public meetings attended by many knowledgeable individuals and representatives of interested organizations. In addition, there have been a number of important scientific conferences, symposia, and colloquia on PM issues, sponsored by the EPA and others, in the U.S. and abroad, during this period. While significant uncertainties exist, the review of the health effects information has been thorough and deliberate. In the judgment of the Administrator, this intensive evaluation of the scientific evidence has provided an adequate basis for regulatory decision making at this time, as well as for the comprehensive research needs document recently developed by EPA, and reviewed by CASAC and others, for improving our future understanding of the relationships between ambient PM exposures and health effects.

The health effects information and human risk assessment were summarized in the proposal and are only briefly outlined below in this unit. Subsequent units provide a more complete discussion of the Administrator's rationale, in light of key issues raised in public comments, for concluding that it is appropriate to revise the current primary standards (Unit II.B. of this preamble) and to revise the specific elements of the standards including indicator (Unit II.C. of this preamble); averaging time, form, and level of new $PM_{2.5}$ standards (Units II.D., II.E., and II.F. of this preamble); and averaging time, form, and level of revised PM_{10} standards (Unit II.G. of this preamble).

2. *Summary of the health effects evidence.* In brief, since the last review of the PM criteria and standards, the most significant new evidence on the health effects of PM is the greatly expanded body of community epidemiological studies. The Criteria Document stated that these recent studies provide ''evidence that serious health effects (mortality, exacerbation of chronic disease, increased hospital admissions, etc.) are associated with exposures to ambient levels of PM found in contemporary U.S. urban airsheds even at concentrations below current U.S. PM standard'' (U.S. EPA, 1996a; p. 13-1). Although a variety of

responses to constituents of ambient PM have been hypothesized to contribute to the reported health effects, the relevant toxicological and controlled human studies published to date have not identified any accepted mechanism(s) that would explain how such relatively low concentrations of ambient PM might cause the health effects reported in the epidemiological literature.

Unit II.A. of the proposal further outlines key information contained in the Criteria Document, Chapters 10-13, and the Staff Paper, Chapter V, on the known and potential health effects associated with airborne PM, alone and in combination with other pollutants that are routinely present in the ambient air. The information highlighted there summarizes:

(1) The nature of the effects that have been reported to be associated with ambient PM, which include premature mortality, aggravation of respiratory and cardiovascular disease (as indicated by increased hospital admissions and emergency room visits, school absences, work loss days, and restricted activity days), changes in lung function and increased respiratory symptoms, changes to lung tissues and structure, and altered respiratory defense mechanisms.

(2) Sensitive subpopulations that appear to be at greater risk to such effects, specifically individuals with respiratory disease and cardiovascular disease and the elderly (premature mortality and hospitalization), children (increased respiratory symptoms and decreased lung function), and asthmatic children and adults (aggravation of symptoms).

(3) An integrated evaluation of the health effects evidence, with an emphasis on the key issues raised in assessing community epidemiological studies, including alternative interpretations of the evidence, both for individual studies and for the evidence as a whole.

(4) The PM fractions of greatest concern to health.

The summary in the proposal will not be repeated here. EPA emphasizes that the final decisions on these standards take into account the more comprehensive and detailed discussions of the scientific information on these issues contained in the Criteria Document and Staff Paper, which were reviewed by the CASAC and the public.

3. *Key insights from the risk assessment.* The Staff Paper presents the results of a quantitative assessment of health risks for two example cities, including risk estimates for several categories of health effects associated with: existing PM air quality levels, projected PM air quality levels that would occur upon attainment of the current PM_{10} standards, and projected PM air quality levels that would occur upon attainment of alternative $PM_{2.5}$ standards. The risk assessment is intended as an aid to the Administrator in judging which alternative PM NAAQS would reduce risks sufficiently to protect public health with an adequate margin of safety, recognizing that such standards will not be risk-free. The risk assessment is described more fully in the Staff Paper and summarized in the proposal. Related technical reports and updates[7] have been placed in the docket (Abt Associates, 1996a,b; 1997a,b).

EPA emphasizes that it places greater weight on the overall conclusions derived from the studies—that PM air pollution is likely causing or contributing to significant adverse effects at levels below those permitted by the current standards—than on the specific concentration-response functions and quantitative risk estimates derived from them. These quantitative risk estimates include significant uncertainty and, therefore, should not be viewed as demonstrated health impacts. EPA believes, however, that they do represent reasonable estimates as to the possible extent of risk for these effects given the available information. Keeping in mind the important uncertainties inherent in any such analyses, the key insights from the risk assessment that are most pertinent to the current decision include:

(1) Fairly wide ranges of estimates of the incidence of PM-related mortality and morbidity effects and risk reductions associated with attainment of alternative standards were calculated for the two locations analyzed when the effects of key uncertainties and alternative assumptions were considered. Significantly, the combined analysis for these two cities alone found that the risk remaining after attaining the current PM_{10} standards was on the order of hundreds of premature deaths each year, hundreds to thousands of respiratory-related hospital admissions, and tens of thousands of additional respiratory related symptoms in children.

(2) Based on the results from the sensitivity analyses of key uncertainties and the integrated uncertainty analyses, the single most important factor influencing the uncertainty associated with the risk estimates is whether or not a threshold concentration exists below which PM-associated health risks are not likely to occur.

(3) Over the course of a year, the few peak 24-hour $PM_{2.5}$ concentrations appear to contribute a relatively small amount to the total health risk posed by the entire air quality distribution as compared to the aggregated risks associated with the low to mid-range concentrations.

(4) There is greater uncertainty about both the existence and the magnitude of estimated excess mortality and other effects associated with PM exposures as one considers increasingly lower concentrations approaching background levels.

B. Need for Revision of the Current Primary PM Standards

1. *Introduction.* The overarching issue in the present review of the primary NAAQS is whether, in view of the advances in scientific knowledge reflected in the Criteria Document and Staff Paper, the existing PM standards should be revised and, if so, what revised or new standards would be appropriate. The concluding section of the integrative synthesis of health effects information in the Criteria Document, which CASAC characterized as EPA's ''best ever example of a true integrative summary of the state of knowledge about the health effects of airborne PM,'' (Wolff, 1996b) provides the following summary of the science with respect to this issue:

> The evidence for PM-related effects from epidemiological studies is fairly strong, with most studies showing increases in mortality, hospital admissions, respiratory symptoms, and pulmonary function decrements associated with several PM indices. These epidemiological findings cannot be wholly attributed to inappropriate or incorrect statistical methods, misspecification of concentration-effect models, biases in study design or implementation, measurement errors in health endpoint, pollution exposure, weather, or other variables, nor confounding of PM effects with effects of other factors. While the results of the epidemiological studies should be interpreted cautiously, they nonetheless provide ample reason to be concerned that there are detectable health effects attributable

[7] The risk assessment results that appear in the Staff Paper and are summarized in the proposal have been updated to include analyses of the particular forms of standard alternatives contained in the proposal and to correct estimates for one effects category (mortality from long-term exposure) to reflect the actual statistics used in the study upon which they were based (Pope et al., 1995). The corrections, which cumulatively reduce estimates of mortality associated with long-term exposures by 20 to 35%, have no effect on risk estimates for mortality associated with short-term exposures or the estimates for any other effects. Because the key sensitivity analyses that provide additional insights regarding thresholds, copollutants, averaging time and related issues involved the short-term exposure studies, none of these results are affected by changes to the long-term exposure risk estimates.

to PM at levels below the current NAAQS. [U.S. EPA, 1996a, p. 13-92]

Given the nature of the health effects in question, this finding, which is based on a large number of studies that used PM_{10} measurements, as well as studies using other indicators of PM, clearly indicates that revision of the current PM NAAQS is appropriate. Quite apart from the issue of whether PM_{10} should be the sole indicator for the PM NAAQS, the extensive PM epidemiological data base provides evidence of serious health effects (e.g., mortality, exacerbation of chronic disease, increased hospital admissions) in sensitive populations (e.g., the elderly, individuals with cardiopulmonary disease), as well as significant adverse health effects (e.g., increased respiratory symptoms, school absences, and lung function decrements) in children. Moreover, these effects associations are observed in areas or at times when the levels of the current PM_{10} standards are met. Although the increase in relative risk is small for the most serious outcomes, EPA believes it is significant from an overall public health perspective, because of the large number of individuals in sensitive populations that are exposed to ambient PM, as well as the significance of the health effects involved (U.S. EPA, 1996a, p. 1-21). The results of the two-city PM risk assessment reinforce these conclusions regarding the significance of the public health risk—even under a scenario in which the current PM_{10} standards are attained.

While the lack of demonstrated mechanisms that explain the extensive body of epidemiological findings is an important caution, which presents difficulties in providing an integrated assessment of PM health effects research, a number of potential mechanisms have been hypothesized in the recent literature (U.S. EPA, 1996b; p. V-5 to V-8; appendix D). Moreover, qualitative information from laboratory studies of the effects of particle components at high concentrations and dosimetry considerations suggest that the kinds of effects observed in community studies (e.g., respiratory- and cardiovascular-related responses) are at least plausibly related to inhalation of PM.[8] Indeed, as discussed in the Criteria Document and section V.E of the Staff Paper, the consistency of the results of the epidemiological studies from a large number of different locations and the coherent nature of the observed effects[9] are suggestive of a likely causal role of ambient PM in contributing to the reported effects.

2. *Comments on scientific basis for revision.* A majority of the public comments received on the proposal agreed that, based on the available scientific information, the current PM_{10} standards are not of themselves sufficient to protect public health and it would be appropriate to revise them. Included in those calling for revisions to the current standards are many public health professionals, including numerous medical doctors and academic researchers. For example, a group of 27 members of the scientific and medical community recognized as having substantial expertise in conducting research on the health effects of air pollution stated:

> Health studies conducted in the U.S. and around the world have demonstrated that levels of particulate and ozone air pollution below the current U.S. National Air Quality Standards exacerbate serious respiratory disease and contribute to early death. A large body of scientific and medical evidence clearly indicates that the current NAAQS are not sufficiently protective of public health. [Thurston, 1997]

Similar conclusions were reached in a letter signed by more than 1,000 scientists, clinicians, researchers, and other health care professionals (Dickey, 1997). The cosigners to this letter argued that tens of thousands of hospital visits and premature deaths could be prevented with the proposed air quality standard revisions. In fact, these commenters argued that even stronger standards than those proposed by EPA are needed to protect the health of the most vulnerable residents of our communities.

A number of State and local government authorities also submitted comments in support of adopting new air quality standards for fine particulate matter. The commenters concurred with conclusions reached through the EPA's peer review process that the PM standards should be revised to protect public health. A number of these commenters suggested that the standards proposed by EPA should be even stronger, while several other State agencies recommended that EPA adopt $PM_{2.5}$ standards, but at less stringent levels. A number of the comments from states supporting even stronger standards acknowledged the lack of demonstrated mechanism(s) and other uncertainties but stressed the strength of the other evidence in urging EPA to set protective standards.

Many comments were also received from representatives of environmental or community health organizations that supported the adoption of air quality standards for $PM_{2.5}$. These commenters agreed with EPA's finding that a large body of compelling evidence demonstrates that exposure to particulate matter pollution, in general, is associated with premature death, aggravation of heart and lung diseases, increased respiratory illness and reduced lung function. They agreed with EPA that these studies present a consistent and coherent relationship between exposure to PM and both mortality and various measures of morbidity. However, the majority of these commenters argued that EPA's proposed standards for $PM_{2.5}$ were inadequate and recommended adoption of more stringent levels of the 24-hour and/or annual air quality standards for $PM_{2.5}$. Many of these commenters also urged EPA to revise the NAAQS for PM_{10} to be more protective of public health. These commenters based their recommendations on the findings of the studies that were reviewed in the preparation of the Criteria Document and Staff Paper. One commenter used results from five of these studies as the basis for recommending $PM_{2.5}$ standards of 10 $\mu g/m^3$ (annual) and 18 $\mu g/m^3$ (24-hour) (Dockery et al., 1993; Pope et al., 1995; Schwartz et al., 1996; Schwartz et al., 1994; Thurston et al., 1994). The commenters agreed with EPA on the significance of these studies' results and the need to revise the PM standards, while differing with EPA's interpretation of the findings for purposes of developing the proposed PM standards.

Several commenters made reference to the conclusions of a number of international scientific panels regarding the health effects of exposure to airborne particulate matter—the British Expert Panel on Air Quality Standards, the British Committee on the Medical Effects of Air Pollutants, the World Health Organization, the Canadian Ministry of Environment, Lands and Parks, and the Health Council of the Netherlands -- and argued that all these panels found that PM concentrations equivalent to the current U.S. standards for PM_{10} are not protective of human health and made recommendations for greater protection. One commenter noted that the findings of the British Health Panel have resulted in a British

[8] As discussed more fully below in this unit, epidemiological studies alone cannot be used to demonstrate mechanisms of action, but they can provide evidence useful in making inferences with regard to causal relationships (U.S. EPA, 1996b, p. V-9).

[9] As noted in the proposal, the kinds of effects observed in the epidemiological studies are logically related. For example, the association of PM with mortality is mainly linked to respiratory and cardiovascular causes, which is coherent with observed PM associations with respiratory and cardiovascular hospital admissions and respiratory symptoms. Further, similar categories of effects are seen in long- and short-term exposure studies.

proposal to adopt a 24-hour PM_{10} standard of 50 $\mu g/m^3$, which is one-third the level of the current U.S. NAAQS.

In these comments, some toxicological studies were cited as providing evidence for toxicity of particulate pollution. These commenters disagreed with arguments that PM standards cannot be adopted due to a lack of a sufficient understanding of the biological mechanism of injury. The commenters argued that there is sufficient evidence that particulate pollution is associated with adverse health effects to make it inappropriate to delay the establishment of standards while further studies are undertaken. This group of commenters was also critical of arguments against the establishment of additional PM standards based on the possibility of confounding by other pollutants, and urged that more attention be paid instead to the possible additive or synergistic effects of multiple pollutant exposures.

In general, the EPA agrees with these commenters' arguments regarding the need to revise the PM standards. The scientific studies cited by these commenters were the same studies used in the development of the Criteria Document and the Staff Paper, and the EPA agrees that there is a sufficient body of evidence that the current NAAQS for PM are not adequately protective of the public health. For reasons detailed in Unit II.F. of this preamble and in the Response to Comments, EPA disagrees with aspects of these commenters' views on the level of protection that is appropriate and supported by the available scientific information.

Another body of commenters, including almost all commenters representing businesses and industry associations, many local governmental groups and private citizens, and some States opposed revising the standards. Many of these commenters argued that the available scientific evidence does not provide an adequate basis for revising the current standards. The central arguments made by these commenters can be divided into two categories: (1) General comments on the appropriateness of relying on the epidemiological evidence for making regulatory decisions, and (2) more specific comments challenging EPA's appraisal of the consistency and coherence of the available information, EPA's conclusions regarding causality, and the use of these studies for risk assessment and decisions on whether to revise the standards. While EPA has included comprehensive responses to these comments in the Response to Comments, certain key points are summarized below in this unit.

a. *General comments on the use of epidemiological studies.* The first category of comments was largely derived from ad hoc panels of occupational and other epidemiological experts, consulting groups, and individual consultants. Most of these individuals and groups commented on the use of epidemiology in reaching scientific and policy conclusions primarily from an occupational or hazard assessment perspective, in contrast to the perspective of the review of ambient PM criteria and standards, where the use of community air pollution epidemiological studies are central. Citing accepted criteria used in evaluating epidemiological studies to assess the likelihood of causality (most notably those of Sir Austin Bradford Hill, 1965), these commenters argued that in the absence of a demonstrated biological mechanism, the relative risks of effects in the PM epidemiological studies are too low (less than values variously cited as 1.5 to 2.0) to reach any conclusions regarding causality or to form the basis for regulations. In general, the commenters applied these criteria to a subset of studies evaluated in the Criteria Document, including as few as two long-term exposure studies (EOP Group) (API, 1997), a group of 9 selected studies (Greenland panel) (API, 1997), those studies cited in the proposal (AIHC, 1997), or as many as 23 selected short-term exposure studies examined in a recently published review paper (Gamble and Lewis, 1996).

Based on a careful review of these comments, EPA notes a number of limitations in these commenters' evaluations of the epidemiological studies that they considered, as discussed in detail in the Response to Comments. In summary, EPA notes that these commenters provided scientific advice and conclusions that are in substantial disagreement with the conclusions of the review reflected in the Criteria Document and Staff Paper. EPA stands behind the scientific conclusions reached in these documents regarding the appropriate use of the available community epidemiological studies. These documents were the product of an extended public process that included conducting public workshops involving the leading researchers in the field, drafts of the Criteria Document and Staff Paper providing opportunities for public scrutiny and comment on, and, not least, receiving the advice of an independent panel of air pollution experts, including epidemiologists.

EPA clearly specified the key criteria by which it evaluated the available epidemiological studies in section 12.1.2 of the Criteria Document, with substantial reliance on those specified by Hill (1965). In rejecting results with relative risks less than 1.5 to 2 as meaningful absent demonstrated biological mechanisms, the commenters fail to note that Hill and other expert groups (U.S. DHEW, 1964) have emphasized that no one criterion is definitive by itself, nor is it necessary that all be met in order to support a determination of causality (U.S. EPA, 1996a, p. 12-3).

With respect to biological plausibility, Hill noted that ''this is a feature I am convinced we cannot demand. What is biologically plausible depends upon the biological knowledge of the day'' (Hill, 1965). This statement is clearly pertinent to the toxicological and mechanistic understanding of the effects of PM and associated air pollutants, especially at lower concentrations. It is also important to stress that while the mechanistic evidence published as of the time the Criteria Document closed does not provide quantitative support for the epidemiological results, neither can such limited evidence refute these findings. It is also important to stress that our understanding of biological mechanisms for PM pollution effects is not sufficient to explain the effects observed at much higher concentrations in air pollution episodes, for which causality is generally accepted. Moreover, the toxicological literature has only recently begun to examine animal models (or controlled human studies) that might reflect the sensitive populations in question (the elderly, individuals with chronic respiratory and cardiovascular disease) or that adequately reproduce all of the physico-chemical properties of particles in the ambient atmosphere. In short, the absence of evidence of a particular mechanism is hardly proof that there are no mechanisms that could explain the effects observed so consistently in the epidemiological studies. The absence of biological mechanisms did not deter CASAC from recommending revisions to the PM standards in 1982, 1986, and again in 1996.

While Hill appropriately emphasized the strength of the association as important (e.g., size of the relative risk), he also pointed out that ''We must not be too ready to dismiss a cause-and-effect hypothesis merely on the ground that the observed association appears to be slight. There are many occasions in medicine when this in truth is so'' (Hill, 1965). EPA believes that the effects of air pollution containing PM is such a

case. Unlike the ''textbook'' examples of unlikely significant associations provided by some commenters (e.g., ice cream consumption correlated with heat stroke), the abundant epidemiological literature on combustion particles documents numerous occasions in which single short-term episodes of high air pollution produced unequivocally elevated relative risks. For the week of the well documented 1952 London air pollution episode, for example, the relative risk of mortality for all causes was 2.6, while the relative risk for bronchitis mortality was as high as 9.3 (Ministry of Health, 1954). Hospital admissions also increased by more than a factor of two. British epidemiologists in the 1950s concluded that increased mortality was likely when PM (as mass calibrated British Smoke <4.5 μm in aerodynamic diameter) exceeded 500 $\mu g/m^3$ (Martin and Bradley, 1960). This is only about a factor of 3 higher than that allowed by the current PM standard. Unlike the ''textbook'' and other unlikely statistical associations noted by some commenters, where the only evidence is for low relative risk, clear and convincing links between high-level PM concentrations and mortality and morbidity buttress the findings of similar associations at much lower PM concentrations as suggested in the more recent epidemiological literature.

These commenters also appear to ignore several epidemiological studies conducted at low PM concentrations in U.S. and European cities, including both short- and long-term exposures to PM air pollution, that find statistically significant relative risks of respiratory symptom categories in children in the range of 1.5 to 5 (Schwartz et al., 1994; Pope and Dockery, 1992; Braun-Fahrlander et al., 1992; Dockery et al., 1989; Dockery et al., 1996). Concentrations in these studies extend from moderately above to well below those permitted by the current PM_{10} standards. While, as noted in the proposal, most of the recent epidemiological studies of mortality and hospital admissions report comparatively small relative risks, the findings of relative risks well in excess of the 1.5 to 2 criterion noted by commenters for earlier studies of high PM episodes, as well as the relative risks of 1.5 to 5 reported in more recent studies of less serious, but still important effects categories, lend credibility to EPA's interpretation of the results.

In addition to basing their conclusions primarily on their own assessment of a limited set of studies, this group of commenters reached different conclusions about the consistency of the observed associations because of their assumptions that all model building strategies by all authors are equally valid. Even the most thorough of these treatments (Gamble and Lewis, 1996) shared this flaw, particularly in the discussion of the series of Philadelphia mortality studies and in the discussion of modeling approaches. The authors' treatment of modeling and confounding issues was further limited because they did not include the most recent Philadelphia results (Samet et al., 1996a,b) sponsored by the Health Effects Institute (HEI, 1997). One of the important functions of the Criteria Document is to evaluate the strengths and limitations of various studies. As discussed more fully below in this unit, the Criteria Document found that some of the studies cited by commenters as suggesting a lack of consistency had important limitations. In general, these commenters' analyses suffered by ignoring the much more thorough critical review of these studies and issues contained in the Criteria Document, notably that in section 12.6 on alternative modeling approaches.

EPA also rejects the notion advanced by these commenters that epidemiological studies must use personal exposure monitoring to be considered for regulatory purposes. In particular, commenters ignore the significant strengths of the time-series studies and prospective cohort studies relied on by EPA as compared to cross-sectional epidemiological studies. Time-series studies, such as the daily mortality studies, look at changes in response rate in relation to changes in weather and air pollution over time intervals of a few days. This controls for other factors such as smoking and socioeconomic status, which are little changed during such short intervals. Prospective cohort studies (e.g., Pope et al., 1995; Raizenne et al., 1996), on the other hand, look at changes in health status in a selected cohort of individuals, which allows direct adjustment for smoking status, socioeconomic status, and other subject-specific factors. The commenters also ignore the Criteria Document conclusions on how properly conducted monitoring can provide an adequate index of population exposure to ambient air pollution in such studies that, as detailed below, is more relevant to establishing ambient air quality standards (U.S. EPA 1996a, chapter 7). Although personal monitoring may be practical for some occupational and epidemiological studies, and has been employed in some past studies of air pollution, it is not realistic to require personal monitors in air pollution studies of daily mortality, which require urban scale population data over a period of years. Furthermore, the use of community monitoring-based epidemiological studies as a basis for establishing standards and guidelines has a long history in air pollution, including the British authorities' response to the London episodes and the establishment of the original U.S. NAAQS in 1971. Rejecting the use of the vast array of such studies on this basis alone would also go against the advice of the independent scientific experts on every CASAC panel that has addressed the subject of PM pollution through the years, each of which has recommended general PM standards based primarily on the results of community epidemiological studies (Friedlander, 1982; Lippmann, 1986; Wolff, 1996b). As noted above in this unit, EPA has included a more detailed discussion of its responses to these comments in the Response to Comments.

b. *Specific comments on epidemiologic studies.* The second group of commenters noted above made more specific challenges to EPA's assessment of the epidemiological studies. These comments, although overlapping some of those made by the first group, were generally made by commenters who have taken a more active role in the review of the Criteria Document and Staff Paper. These commenters asserted that the epidemiological evidence on PM is not as consistent and coherent as EPA has claimed, and, in particular, charged that EPA ignored or downplayed a number of studies that the commenters argue contradict the evidence the Agency cited as supporting the consistency and coherence of PM effects. The studies, all of which commenters contend do a better job of addressing one or more key issues, such as confounding pollutants, weather, exposure misclassification, and model specification, than earlier studies, include several that were available during preparation of the Criteria Document, and a number that appeared after the Criteria Document and Staff Paper were completed. Because the status of the later studies differ from that of the earlier ones for purposes of decisions under section 109 of the Act, the two categories are discussed separately below in this unit. Additional responses to comments relating to both sets of studies have been included in the Response to Comments. In addition to the inclusion of specific studies, commenters also raised other issues regarding the limitations of the

epidemiological information and the use of these studies in EPA's two-city risk assessment. Both of these topics are also discussed below in this unit.

(i) *Studies available for inclusion in the criteria review.* With some exceptions, most of the above commenters cited somewhat similar lists of ''negative'' studies that they argue EPA ignored or downplayed in arriving at conclusions on consistency and coherence. Of the most commonly cited studies, the following were available for inclusion in the Criteria Document: daily mortality studies by Styer et al. (1995), Lyon et al. (1995), Li and Roth (1995), Moolgavkar (1995a,b), Wyzga and Lipfert (1995), Lipfert and Wyzga (1995), and Samet et al. (1995, 1996a,b); the long-term exposure mortality study by Abbey et al. (1991); and the re-examination of the Six-City mortality results (Dockery et al., 1993) by Lipfert (1995).

The written record of EPA's evaluations of these studies effectively refutes the claim that the Agency ignored any of these studies and supports the treatment the Agency accorded to each of them. All of the studies available to EPA at the time of CASAC closure on the PM Criteria Document (March 1996) were examined for inclusion in the Criteria Document and Staff Paper, which form the basis for the PM proposal. ''Negative''[10] studies were evaluated in detail along with ''positive'' studies when they were found to have no critical methodological deficiencies, or to point out strengths and limitations. Studies that had more serious problems were generally discussed in less detail, whether positive or negative, than studies with fewer or small deficiencies. The EPA assessments were evaluated by peer reviewers, by CASAC, and by the public.

Most of the short-term exposure studies cited above in this unit are reanalyses and extensions of PM/mortality studies that had been published by other investigators. In general, the Criteria Document concluded that the most comprehensive and thorough reanalyses were those in the series conducted for the HEI, which reanalyzed data sets used in studies from six urban areas in Phase I.A (Samet et al., 1995)[11], with extended analyses for Philadelphia in Phase I.B (Samet et al., 1996a,b). The most important finding in the HEI Phase I.A reanalyses of the six areas is ''the confirmation of the numerical results of the earlier analyses of all six data sets'' (HEI, 1995)[12]. After replicating the original investigators' analyses, Samet et al. (1995) also found similar results analyzing the data using an improved statistical model. The HEI Oversight Committee found

> [I]t is reasonable to conclude that, in these six data sets, daily mortality from all causes combined, and from cardiovascular and respiratory causes in particular, increases as levels of particulate air pollution indexes increase. [HEI, 1995]

It is important to note that these reanalyses by respected independent scientists confirm the reliability and reproducibility of the work of the original investigators, particularly in view of the concerns some commenters have expressed about EPA's reliance on a number of PM studies published by these authors.

The Phase I.A HEI results for Philadelphia also found that it was difficult to separate the effects of PM from those of co-occurring SO_2, in agreement with the Moolgavkar et al.(1995a) analysis. Subsequent HEI work, and several of the other so-called ''negative'' studies cited above in this unit, further examined this issue in terms of confounding or effects modification by one or more co-occurring gaseous pollutants or weather. Contrary to commenters' claims, this issue and these studies received considerable attention in the Criteria Document and Staff Paper, and the overall implications and conclusions from these assessments were summarized in the proposal. In particular, the so-called ''negative'' and other findings of Moolgalvkar et al. (1995a,b) in their Philadelphia and Steubenville studies were discussed in great detail in section 12.6 of the PM Critera Document and compared to those of the original investigators (Schwartz and Dockery, 1992a,b) and other investigators (Li and Roth, 1995; Wyzga and Lipfert, 1995). Further analytical studies of the Philadelphia data set were carried out by HEI (Samet et al., 1996a,b) and have largely resolved many of the uncertainties in the earlier analyses; in EPA's opinion, these studies supersede the results of the original investigators (Schwartz and Dockery, 1992a) and the several earlier reanalyses, including Moolgavkar (1995a), Moolgavkar and Luebeck (1996), Li and Roth (1995), Wyzga and Lipfert (1995), and Samet et al. (1995). Even though TSP is not the best PM indicator for health effects, since it includes a substantial fraction of non-thoracic particles, the extended Criteria Document assessment (U.S. EPA, 1996a, pp. 12-291 to -299; 12-327) of the Phase I.B HEI analyses in Philadelphia (Samet et al., 1996a,b) serves to support the following findings:

(1) The mortality effects estimates for TSP do not depend heavily on statistical methods when appropriate models are used.

(2) Estimated PM effects are not highly sensitive to appropriate methods for adjusting for time trends and for weather.

(3) Air pollution has significant health effects above and beyond those of weather.

(4) Copollutants such as ozone, CO, and NO_2 may be important predictors of mortality, but their effects can be substantially separated from those of TSP and SO_2.

(5) The health effects of TSP in Philadelphia cannot be completely separated from SO_2, which is itself a precursor of fine particles, based solely on the epidemiological analyses in this single city.

The most recent HEI Oversight Committee comments on these studies (HEI, 1997), which were submitted to the docket by HEI, state that:

> Although individual air pollutants (TSP, SO_2, and ozone) are associated with increased daily mortality in these data, the limitations of the Philadelphia data make it impossible to establish that particulate air pollution alone is responsible for the widely observed associations between increased mortality and air pollution in that city. All we can conclude is that it appears to play a role. [HEI, 1997; p.38.]

While recognizing the limitations in the conclusions that can be made based on studies in a single city, the Oversight Committee endorses the approach taken by EPA in evaluating a broader set of epidemiological studies:

> Consistent and repeated observations in locales with different air pollution profiles can provide the most convincing epidemiological evidence to support

[10] The term ''negative'' studies, as used in these comments, should not be construed to mean those in which there is a negative effects estimate (either significant or non-significant) for the nominal cause. As used by these commenters, the term also includes statistically non-significant positive effect estimates. In other words, the commenters define ''positive'' studies as including only those in which the effect estimate is both positive and statistically significant.

[11] Data sets were those used in the original studies by Dockery et al. (1992) for St. Louis and Eastern Tennessee; Pope et al. (1992) for Utah Valley; Schwartz and Dockery (1992a) for Philadelphia; Schwartz (1993) for Birmingham; and a portion of the Santa Clara data from Fairley (1990). The data set from the Moolgavkar et al. (1995a) Philadelphia reanalysis was also included (Samet et al., 1995).

[12] The HEI Board of Directors appointed an eight member Oversight Committee consisting of leading scientists in several disciplines relevant to air pollution epidemiology to oversee key aspects of the project and to prepare HEI's assessment of the results.

generalizing the findings from these models. This has been the approach reported by the EPA in its recent Criteria Document and Staff Paper. [HEI, 1997; p. 38.]

As noted in the proposal, based on this approach, EPA's assessment of numerous mortality studies concludes that when studies are evaluated on an individual basis, the PM-effects associations are valid and, in a number of studies, not seriously confounded by co-pollutants (U.S. EPA, 1996a; p. 13-57); and when a collection of studies from multiple areas with differing concentrations of PM and co-pollutants are examined together, the association with PM_{10} remains reasonably consistent across a wide range of concentrations of these potentially influential pollutants (U.S. EPA, 1996a; p. 12-33; U.S. EPA, 1996b; p. V-55).

In addition to relying on the most comprehensive and best analyses in evaluating the reanalysis in Philadelphia and other areas, the Criteria Document gave less weight to both so-called ''negative'' and ''positive'' studies with methodogical limitations. In particular, EPA agreed with the epidemiological experts on CASAC (Lippmann et al., 1996; Samet, 1995) that the Li and Roth (1995) study approach of using a ''panoply'' of different modeling strategies to produce seemingly conflicting findings provides little useful insight and is superseded by the HEI report. The attempt by Lipfert and Wyzga (1995) to address relative effects of different pollutants was considered inconclusive (Lippmann et al., 1996) and flawed by the use of a metric (elasticity) that ignores the absolute concentrations of the pollutants being compared (see Response to Comments).

Further, the Steubenville studies and reanalyses (Schwartz and Dockery, 1992b; Moolgavkar, 1995b) were discussed in detail to examine methodologies, and the differences in relative risks between the two were regarded as small (U.S. EPA, 1996a, p. 12-280 to 283). Both studies used TSP as the PM indicator variable, and they are augmented by the more recent findings of Schwartz et al. (1996) that examine PM_{10} and its components. The mixed results by Lyon et al. (1995) in Utah Valley are compromised by loss of information related to the methodology (U.S. EPA, 1996a, p. 12-58). As noted above, subsequent reanalyses of the Utah Valley study by HEI (Samet et al., 1995) as well as by Pope and Kalkstein (1996) confirmed the original findings of Pope et al. (1992) using different model specifications. The Salt Lake City study by Styer et al. (1995) was mentioned in the PM Criteria Document, but received little discussion because aspects of the methodological approach limited its statistical power to detect effects. The analysis of Chicago mortality data in the same paper shared these problems, particularly for seasonal analyses; in this larger city, they nonetheless found significant associations on an annual basis between PM_{10} and mortality that are consistent with other studies. In short, the record shows that EPA did not ignore these short-term exposure studies cited by commenters; moreover, EPA's assessment of these studies is consistent with the views of four researchers on the CASAC panel who have extensive involvement in conducting population studies of air pollution (Lippmann et al., 1996).[13]

Similarly, EPA believes that appropriate treatment and weight were given to studies of long-term exposure and mortality. EPA concluded that the lack of associations in the Abbey et al. (1991) prospective cohort study were not inconsistent with two other such studies because the use of days of peak TSP levels as the PM indicator (instead of PM_{10} or $PM_{2.5}$) is inappropriate for California cohorts exposed to both urban smog and fugitive dust episodes, and the overall sample size may have been too small to detect significant effects (U.S. EPA, 1996b; pp. V-17 to -18). The inadequacy of Lipfert's (1995) application of state-wide average sedentary lifestyle data to adjust mortality for the six cities studied by Dockery et al. (1993), in which superior subject-specific body mass index data had already been considered, was also noted and addressed in the Staff Paper (U.S. EPA, 1996b; p. V-16). Again, EPA did not ignore these studies; the rationale for giving them less weight was clearly articulated in the documents reviewed by CASAC and judged appropriate for use in standard setting.

While the proposal presents only a summary discussion of key Criteria Document and Staff Paper findings, EPA believes that discussion is fully consistent with the state of the science. Furthermore, the proposal highlights the nature of alternative viewpoints on the epidemiology in a quotation from the Criteria Document (61 FR 65644, December 13, 1996) and cites explicitly the views of most of the authors noted above in this unit (Moolgavkar et al., 1995b; Moolgavkar and Luebeck, 1996; Li and Roth, 1995; Samet et al., 1996; Wyzga and Lipfert, 1995). The proposal also summarizes EPA conclusions based on all of the literature as assessed in the Criteria Document and Staff Paper with respect to issues raised in these and other studies, including potential confounding by independent risk factors such as weather and other pollutants, choice of statistical models, use of outdoor monitors, and exposure misclassification.

More specifically, in the proposal EPA has not ignored the view advanced by some that the results of individual studies of multiple pollutants, such as the HEI Philadelphia studies, are more suggestive of an ''air pollution'' effect than an effect of PM alone. Indeed, the proposal notes that it is reasonable to expect that other pollutants may play a role in modifying the magnitude of the estimated effects of PM on mortality, either through pollutant interactions or independent effects (61 FR 65645, December 13, 1996). Based on the large body of evidence at hand, however, EPA cannot accept the suggestion that such multi-pollutant studies are in any way ''negative'' with respect to EPA's conclusions that PM, alone or in combination with other pollutants, is associated with adverse effects at levels below those allowed by the current standards. This conclusion is based not only on the consistency of PM effects across areas with widely varying concentrations of potentially confounding copollutants, but also on the extended analyses of the Philadelphia studies in the Criteria Document and Staff Paper.

Because commenters have tended to ignore the latter analyses, it is appropriate to summarize them here briefly. As noted above in this unit, the Criteria Document assessment of the Philadelphia studies finds that PM can reasonably be distinguished from potential effects of all pollutants except SO_2. The Staff Paper builds on this analysis through an integrated assessment that draws on information from atmospheric chemistry, human exposure studies, and respiratory tract penetration results to provide insight as to which of these two pollutants is more likely to be responsible for mortality in the elderly and individuals with cardiopulmonary disease (U.S. EPA 1996b; pp. V-46 to -50). That assessment notes that the inhalable (PM_{10}), including the fine ($PM_{2.5}$), components of TSP are more likely than SO_2 to penetrate and remain indoors where the sensitive population resides most of the time.[14] In addition, these PM

[13] Their March 20, 1996 letter to the Administrator concludes that the HEI analysis of Philadelphia supersedes earlier analyses, specifically Moolgavkar et al. (1995a), Lipfert and Wyzga (1995), and Li and Roth (1995), and points out the limitations of Styer et al. (1995).

[14] In response to comments on this rulemaking, some papers submitted by industry commenters

Continued

components, especially $PM_{2.5}$, penetrate far more effectively to the airways and gas exchange regions of the lung than does SO_2. Furthermore, in Philadelphia, it is possible that SO_2 is a surrogate for fine particulate acid sulfates. For these reasons, even though statistical analyses of the Philadelphia data set cannot fully distinguish between these two highly correlated pollutants, EPA believes that the weight of the available evidence from an integrated assessment more strongly supports the notion that PM is playing an important direct role in the observed mortality effects associations in Philadelphia. Moreover, as noted above in this unit, in some other locations with significant PM-mortality associations, ambient SO_2 levels are too low to confound PM.

(ii) *Recent studies available after completion of criteria review.* As noted above in this unit, other studies cited by some commenters as so-called ''negative'' evidence ignored by EPA were published or otherwise made available only after completion of the PM Criteria Document. EPA agrees that it did not rely on these studies, based on its long-standing practice of basing NAAQS decisions on studies and related information included in the pertinent air quality criteria and available for CASAC review.[15] Although EPA has not relied on such studies in this review and decision process, the Agency nevertheless has conducted a provisional examination of these and other recent studies to assess their general consistency with the much larger body of literature evaluated in the Criteria Document.[16] EPA has placed its examination of recent studies in the rulemaking docket.

Among the most frequently cited new studies relied on by commenters were Davis et al. (1996), Moolgavkar et al. (1997), and Roth and Li (1997). Davis et al. (1996) conducted a reanalysis of the Birmingham mortality data set originally investigated in Schwartz (1993). At the time of the close of the public comment period, the paper based on this manuscript had not been accepted for publication in a peer reviewed journal (Sacks, 1997). Commenters nevertheless highlight the authors' claim that ''when humidity is included among the meteorological variables (it is excluded in the analysis by Schwartz [1993]), we find that the PM_{10} effect is not statistically significant.'' EPA's review found important factual errors in this study. Contrary to Davis et al., Schwartz did include humidity in his 1993 study, and his finding of a hot-and-humid-day effect was reported there. In addition, the PM-related variables used by Davis et al. in their manuscript were not, as the authors claimed, the same as those in Schwartz (1993). Davis et al. also used a different humidity indicator, specific humidity. Reanalysis by one of the co-authors (R. Smith, personal communication, February 8, 1997) showed that when Schwartz's PM metric was used, the estimated PM_{10} effect was of about the same magnitude, and statistically significant at the 0.05 level, even using the characterization of humidity effect proposed by Davis et al. It therefore appears that the Davis et al. PM_{10} result was, in fact, consistent with that of Schwartz, and robust against a very different weather model specification.

Based on its examination of both the content and the publication status of this study, EPA believes the heavy reliance and attention given to it are misguided. In contrast to commenters' assertions, this study does not contradict EPA's conclusions with respect to consistency of the epidemiological evidence and confounding by weather variables; indeed, the consideration of the corrected results would actually support EPA's conclusions. EPA believes this example reinforces the importance of relying on peer reviewed studies and also conducting the kind of critical examination of such studies that takes place in the criteria and standards review process.

Several commenters note that Roth and Li (1997) also reexamined the Birmingham mortality data, as well as hospital admissions data from Schwartz (1994), and produced a number of negative and inconsistent results that depend on temperature effects and choice of statistical model. Preliminary findings from this study were presented by Roth at the May 1996 CASAC meeting. CASAC epidemiologists and statisticians at the meeting pointed out a number of shortcomings, both in the analytical strategy and in details of the models being evaluated.[17] As discussed in more detail in the Response to Comments, the materials from Roth and Li (1997) recently provided to EPA as attachments to public comments show that the deficiencies pointed out at the May 1996 CASAC meeting have not been adequately addressed. EPA concludes that this study does not support commenters' claims.

The paper recently accepted for publication by Moolgavkar et al. (1997) examines hospital admissions and air pollution in Minneapolis and Birmingham and comes to different conclusions than earlier investigators with respect to the role of PM_{10}. While the paper is a useful addition to the literature, the authors clearly do not attempt to replicate the original studies, making the kind of direct comparisons suggested by commenters difficult. The paper finds an air pollution effect in one city that implicates ozone but is unable to separate effects of PM from a group of other pollutants. EPA's provisional examination of this study raises some questions about the methodology, which might usefully be supplemented to further separate pollutants as was done by Samet et al. (1996a,b) in Philadelphia, and about the authors' interpretation of the results in both cities. In any event, EPA does not believe this study negates the PM associations with hospital admissions

---

make statements that are in substantial agreement with these staff conclusions with respect to the likelihood of SO_2 penetrating to indoor environments and the lesser likelihood of affecting sensitive populations indoors (Lipfert and Wyzga, 1997; Lipfert and Urch, 1997).

[15] Since the 1970 amendments, the EPA has taken the view that NAAQS decisions are to be based on scientific studies that have been assessed in air quality criteria [see e.g., 36 FR 8186 (April 30, 1971) (EPA based original NAAQS for six pollutants on scientific studies discussed in the air quality criteria and limited consideration of comments to those concerning validity of scientific basis); 38 FR 25678, 25679-25680 (September 14, 1973) (EPA revised air quality criteria for sulfur oxides to provide basis for reevaluation of secondary NAAQS)]. This longstanding interpretation was strengthened by new legislative requirements enacted in 1977 (section 109(d)(2) of the Act; section 8(c) of the Environmental Research, Development, and Demonstration Authorization Act of 1978) for CASAC review of air quality criteria and reaffirmed in EPA's decision not to revise the ozone standards in 1993. 58 FR 13008, 13013-13014 (March 9, 1993). Some of the commenters now criticizing EPA for not considering the most recent PM studies strongly supported the Agency's interpretation in the 1993 decision (UARG, 1992).

[16] As discussed in EPA's 1993 decision not to revise the NAAQS for ozone, new studies may sometimes be of such significance that it is appropriate to delay a decision on revision of NAAQS and to supplement the pertinent air quality criteria so the new studies can be taken into account. 58 FR at 13014, March 9, 1993. In the present case, EPA's provisional examination of recent studies suggests that reopening the air quality criteria review would not be warranted even if there were time to do so under the court order governing the schedule for this rulemaking. Accordingly, EPA believes that the appropriate course of action is to consider the newly published studies during the next periodic review cycle.

[17] For example, commenting on the Roth examination of alternative model specifications, Dr. Stolwijk noted ''If you select out of his [Roth's] matrix the things that other people have done, he comes to a different conclusion than when he takes his whole matrix * * *. [Y]ou are going to get a random effect that shows that there is no effect. He [Roth] did this, I think, on purpose in this case. Most epidemiologists, I think, have been trained to limit their observations to something that they can state or would have stated before they started and observe that and base their conclusions on it'' [U.S. EPA 1996(c); May 17, 1996 Transcript, pages 45-46].

reported in a number of other studies cited in the Criteria Document.

Another recent paper by Lipfert and Wyzga (1997) provides analyses suggesting that differential measurement error might account for some or all of the observation by Schwartz et al. (1996) that daily mortality is more strongly associated with fine ($PM_{2.5}$) than with coarse ($PM_{10-2.5}$) PM. EPA staff and CASAC accounted for this possibility, however, and it was factored into both the Staff Paper and CASAC recommendations.[18]

Some commenters have highlighted selected individual papers or summaries from the APHEA[19] project conducted in Europe, and from Roth (1996), calling attention particularly to negative results found in heavily polluted regions of Eastern Europe. EPA notes that a number of the recent APHEA and other studies in Western Europe have shown significant associations between mortality and air pollution including PM, and that a meta-analysis of 12 Western and Central-eastern European studies ''is supportive of a causal association between PM and SO_2 exposure and all-cause mortality'' (Katsouyanni et al., 1997). The Eastern and Western European studies used differing measurement methods for PM, including PM_{10}, gravimetric ''suspended particles,'' and the British Smoke method.[20] The differences in aerometry and the substantial differences in location and strength of primary PM emissions sources in central and eastern Europe as compared to western Europe or the U.S. might well explain the different results in these unique areas. Consequently, integration of these results would involve comprehensive examination of the various PM instruments used, monitor siting in relation to sources, mass calibration procedures and other aspects of these studies.[21] EPA notes that a number of European authorities, who are familiar with this recent literature, have proceeded with recommendations to strengthen their health guidelines, risk assessments, or regulations for PM.[22]

Aside from the recent literature cited by these commenters, there are a number of other recent epidemiological studies that, if considered in today's decision, would tend to support EPA's conclusions about the effects of PM at lower concentrations, assuming their results were accepted following a full review in the criteria and CASAC process. For example, in addition to the APHEA studies, several other recent epidemiologic studies have reported significant positive associations between PM and health effects (Lipsett et al., 1997; Peters et al., 1997; Borja-Aburto et al., 1997; Delfino et al., 1997; Scarlett et al., 1996; Woodruff et al., 1997; Wordley et al., 1977). In addition, a number of recent toxicologic papers have been accepted or appear in proceedings (Costa and Dreher, 1997; Killingsworth et al., 1997; Godleski et al., 1997) that involve exposure to concentrated ambient fine particles or PM constituents and appear to provide supportive evidence as to the plausibility of the effects that have been reported epidemiologically. If considered in this decision, these studies would also provide biological support for the epidemiological observation that certain susceptible groups (notably those with cardiopulmonary disease) are most likely to be affected by PM, again assuming the results were sustained in the full criteria and CASAC review process.

In summary, EPA has conducted a provisional assessment of the more recent scientific literature. Based on this provisional assessment, EPA disagrees with commenters' assertion that full consideration of selected new studies in this decision would materially change the Criteria Document and Staff Paper conclusions on the consistency and coherence of the PM data, or on the need to revise the current standards.

(iii) *Other specific comments on the epidemiological studies.* Aside from their assertion that EPA ignored or downplayed particular studies, this second group of commenters raise additional objections, based on the statistical modeling strategies used and the potential importance of personal exposure misclassification, to EPA's conclusions regarding the consistency of the epidemiological evidence. EPA conclusions on these topics were summarized in the proposal and supported by extensive treatments in the Criteria Document and Staff Paper. With respect to the first issue, commenters argued that sufficient flexibility exists in the analyses of large data sets that it may be possible to obtain almost any result desired through choice of statistical method. Analytical choices include the specific statistical model; methods used to adjust for seasonal variation and the trends in the data; treatment of other variables (e.g., other pollutants, weather, and day of week); ''lag'' structure; and study population.

A more detailed discussion of this issue, which expands on the assessment summarized in the Criteria Document, is included in the Response to Comments. In summary, EPA must reject commenters' contention that legitimate alternative analyses can obtain ''almost any result.'' As outlined above in this unit, EPA's detailed reviews of individual studies have shown that not all methods are equally valid or legitimate. Moreover, strong arguments can be made that the methods and analytical strategies in the studies EPA relied upon are more appropriate approaches than those cited by commenters (e.g., Li and Roth, 1995; Lipfert and Wyzga, 1995; Davis et al., 1996; Roth and Li, 1997). While not all studies have addressed each of the above issues in this unit equally well, the most comprehensive analyses of these issues (e.g., Samet et al., 1995, 1996a,b; Pope and Kalkstein, 1996), as well as the EPA analyses comparing study results for each issue (U.S. EPA, 1996a, pp. 12-261 to 12-305) found that the authors of studies on which EPA

[18] CASAC panelists recommended a discussion of this issue in the Staff Paper. The Staff Paper notes: ''While greater measurement error for the coarse fraction could depress a potential coarse particle effect, this would not explain the results in Topeka relative to other cities. Even considering relative measurement error, these results provide no clear evidence implicating coarse particles in the reported effects.'' (U.S. EPA, 1996b p. V-64). EPA's provisional examination of the Lipfert and Wyzga (1997) paper in the Response to Comments, finds that it is implausible that most of the effect attributed to $PM_{2.5}$ could in fact be due to $PM_{10-2.5}$, since differential measurement error cannot make a weaker effect appear stronger than a stronger one, except under extremely unusual circumstances.

[19] The APHEA (Air Pollution and Health: a European Approach) project was supported by the European Union Environment 1991-1994 Programme to investigate the possible short-term health effects of exposure to low or moderate levels of ambient air pollutants. Eleven European research groups carried out studies in 15 cities (Amsterdam, Athens, Barcelona, Bratislava, Cracow, Helsinki, Koln, Lodz, London, Lyon, Milan, Paris, Poznan, Rotterdam and Wroclaw) in which air pollutant concentration data had been collected for at least 5 years. Initial findings of studies on mortality and hospital admissions were published in a series of papers in Supplement 1 to the Journal of Epidemiology and Community Health in 1996 and a meta-analysis of the mortality data from 12 cities is currently in press (Katsouyanni et al., 1997).

[20] The Roth et al. (1997) study in Prague used a measurement termed ''suspended particles'' that appears to be close to TSP. The relation of this indicator to PM_{10} or $PM_{2.5}$ in this city is not reported. Moreover, this study uses a variant of the problematic methodology in the Roth analyses cited above.

[21] These concerns are consistent with EPA's treatment of a number of European and South American studies that are included in the Criteria Document and contributed to the evaluation of the epidemiology in Chapter 12. Because of differences in aerometry methods and characteristic source classes between North America and other regions of the world, however, the integrative assessment chapter reported results only from studies conducted in the U.S. and Canada (cf. Tables 13-3 to 13-5) in reaching quantitative conclusions for effects estimates.

[22] See, for example, the United Kingdom Air Quality Strategy, 1997; Swiss Federal Commission of Air Hygiene, 1996; World Health Organization Revised Air Quality Guidelines for Europe, In Press).

chiefly relied made appropriate modeling choices. The Criteria Document concludes that: ''[T]he largely consistent specific results, indicative of significant positive associations of ambient PM exposures and human mortality/morbidity effects, are not model specific, nor are they artifactualy derived due to misspecification of any specific model. The robustness of the results of different modeling strategies and approaches increases our confidence in their validity [U.S. EPA, 1996a, p. 13-54].'' While it is true, as evidenced in Li and Roth (1995), that PM-effects data can be randomly manipulated to produce apparently conflicting results, commenters have provided no evidence that different plausible model specifications could lead to markedly different conclusions.

Some commenters have expressed concerns about the reliability of the epidemiological results because some studies showed a lack of correlation in cross-sectional comparisons between outdoor PM measured at central locations and indoor or personal exposures to PM (which includes PM from the outdoor, indoor and personal environments).[23] EPA acknowledged and responded to this issue in chapter 7 of the Criteria Document and the proposal (61 FR 65645, December 13, 1996). The major premise underlying commenters' arguments on this issue is incorrect.[24] The question is not whether central monitoring site measurements contain a signal reflecting actual exposures to total PM from both outdoor and indoor sources at the individual level; the relevant question is whether central monitoring site measurements contain a signal reflecting actual exposures to ambient PM for the subject population, including both ambient PM, while individuals are outdoors, and ambient PM that has infiltrated indoors, while individuals are indoors. The PM standards are intended to protect the public from exposure to ambient PM, not PM generated by indoor or personal sources. There is ample evidence, as discussed in chapter 7 of the Criteria Document, that personal exposure to ambient PM, while outdoors and while in indoor micro-environments, does correlate on a day-to-day basis with concentrations measured at properly sited central monitors (U.S. EPA, 1996a, p. 1-10). EPA has, therefore, concluded that it is reasonable to presume that a reduction in ambient PM concentrations will reduce personal exposure to ambient PM, and that this will protect the public from adverse health outcomes associated with personal exposure to ambient PM.

Commenters have also restated theoretically based concerns on a related issue, namely errors in the measurement of the concentrations of air pollutants, that was summarized in the proposal. In multiple pollutant analyses, measurement error or, more generally, exposure misclassification, could theoretically bias effects estimates of PM or co-pollutants in either direction, introducing further uncertainties in the estimated concentration-response relationships for all pollutants (U.S. EPA, 1996b, pp. V-39 to V-43). Relevant insights on this issue in material appended to public comments (Ozkaynak and Spengler, 1996) have prompted an expanded statistical analysis of the conditions under which such errors could inflate the magnitude of the effects estimates or the significance of PM relative to gaseous pollutants, as has been suggested by Lipfert and Wyzga (1995). This analysis, which is summarized in the Response to Comments, finds that the conditions under which measurement error could inflate the effects estimates or significance of PM relative to other pollutants are restricted to a limited set of statistical relationships. Commenters have not provided evidence that suggest such conditions are likely to occur with respect to the measurement of ambient PM in relation to those for gaseous co-pollutants commonly used in epidemiological studies.[25] Therefore, it appears unlikely that measurement and exposure errors for PM and other pollutants have inflated the estimated effects of PM, even in multivariate analyses. More importantly, the available evidence on the consistency of the PM-effects relationships in multiple urban locations, with widely varying indoor/outdoor conditions and a variety of monitoring approaches, makes it less likely that the observed associations of PM with serious health effects at levels allowed under the current NAAQS are an artifact of errors in measurement of pollution or of exposure (U.S. EPA 1996b, pp. V-39 to V-43).

(iv) *Comments on the PM risk assessment.* As noted in the proposal, uncertainties about measurement errors, exposure misclassification, and the relative effects of copollutants are more important to the quantitative estimates of risk associated with PM than to the existence of valid PM-effects associations at levels found in recent studies. A number of commenters argued that EPA's risk assessment is flawed and incomplete. Chief among the reasons they advanced is that the assessment is based on the same epidemiological studies these commenters argued are inadequate for the reasons summarized and responded to above. Specific comments also addressed the extent to which the risk assessment might overstate risk estimates because it assumes a linear no-threshold relationship and the use of studies that might inflate PM risk due to inadequate consideration of co-pollutants and other potential confounders. The full risk assessment acknowledges these issues and uncertainties, however, and it illustrates the potential influence of such uncertainties in sensitivity analyses (U.S. EPA 1996b; chapter 6, appendix F; Abt Associates, 1996a,b; 1997a,b). For example, Figure 2c in the proposal (61 FR 65653, December 13, 1996)

[23] Paradoxically, some commenters have argued (e.g., Valdberg, 1997) that the PM results are confounded because the weather and other factors that cause daily variations in outdoor pollution will cause similar daily variations in indoor generated air pollution. For this to be true, outdoor ambient pollution concentrations would have to be correlated with personal exposure to indoor generated air pollution such as that from smoking, cleaning, and cooking. This argument is logically inconsistent with the other comments on the lack of any such correlation with personal exposure, and these commenters have offered no scientific evidence to support their claim. In response, EPA has performed and included in the Response to Comments a numerical analysis of the relevant information from the PTEAM exposure study that finds no evidence for such a correspondence in the actual data.

[24] As documented in Chapter 7 of the Criteria Document, time-series community studies observe the effects of varying levels of ambient air pollution; therefore the effects of indoor-generated air pollution would be independent of and in addition to the effects found in these epidemiological studies. Commenters apparently believe EPA is claiming such studies are detecting the effects of daily variations in total PM personal exposure from indoor and outdoor sources. This misunderstanding is evidenced, for example, by Wyzga and Lipfert's (1995) treatment of the difference between ambient monitors and actual personal exposures as ''exposure errors'' and Brown's comment for API that ''if (ambient) PM is causally related to mortality/morbidity, then it is personal PM exposure that must be reduced to have an effect.'' On the contrary, it is personal exposure to ambient PM that must be reduced to address the risk identified in community air pollution studies. Any lack of significant correlation between outdoor PM concentrations and personal exposure to total PM from all sources is irrelevant, except to the extent it may decrease the power of time-series studies to detect the effects of ambient pollution.

[25] The EPA analysis finds that in order for measurement errors in one pollutant variable to significantly bias the estimated effect of another pollutant, three conditions are necessary: (1) The measurement error in the poorly measured pollutant must be very large, roughly at least the same size as the population variability in that pollutant; (2) the poorly measured pollutant must be highly correlated with the other pollutant, either positively or negatively; and (3) the measurement errors for the two pollutants must be highly negatively correlated (Response to Comments, Appendix D). This important factor was not considered in Lipfert and Wyzga (1995) or by commenters.

illustrates the potential influence of what appears to be the most significant uncertainty in current information, whether a population threshold exists below which the effects of PM no longer occur (61 FR 65653, December 13, 1996). EPA notes that a full consideration of the uncertainties, including the analysis summarized above on measurement error, suggests that the epidemiological studies might well have understated the total effects of air pollution; thus, both the direction and the extent of any bias in the risk estimates are less clear than commenters suggest.

EPA believes that, even recognizing the large uncertainties, the key qualitative insights derived from the risk assessment and summarized in Unit II.A.3. of this preamble remain appropriate. While not placing great weight on the specific numerical estimates, EPA believes that the risk analysis confirms the general conclusions drawn primarily from the epidemiological results themselves, that there is ample reason to be concerned that exposure to ambient PM at levels allowed under the current air quality standards presents a serious public health problem.

3. *Key considerations informing the decision.* Having carefully considered the public comments on the above matters, EPA believes the fundamental scientific conclusions on the effects of PM reached in the Criteria Document and Staff Paper, and restated in the introduction to this unit, remain valid. That is, the epidemiological evidence for ambient PM, alone or in combination with other pollutants, shows associations with premature mortality, hospital admissions, respiratory symptoms, and lung function decrements. Despite extensive critical examination in the criteria and standards review, these findings cannot be otherwise explained by analytical, data, or other problems inherent in the conduct of such studies. Although the evidence from toxicological studies available during the criteria review has not revealed demonstrated mechanisms that explain the range of effects reported in epidemiological studies, it does not and cannot refute the observation of such effects in exposed populations. Moreover, the effects observed in the recent epidemiological studies at lower PM concentrations are both coherent with each other and plausible based on the categories of effects observed at much higher concentrations in historic air pollution episodes, laboratory studies of PM effects at high doses, and particle dosimetry studies. The consistency of the results from a large number of locations and the coherent nature of the observed results suggest a likely causal role of ambient PM in contributing to the reported effects (U.S. EPA, 1996a; p. 13-1). Many of the studies showing PM effects were conducted in areas where the current PM_{10} standards are largely met, and both the studies and EPA's risk assessment suggest that the collective magnitude of the effects reflects a significant public health problem.

For these reasons, and having considered public comments on this issue, the Administrator concludes that the review of the criteria and standards provides strong evidence that the current PM_{10} standards do not adequately protect public health, and that revision of the standards is not only appropriate, but necessary.

Aside from that conclusion, the appropriateness of continuing to rely on the use of PM_{10} as the sole indicator for revised PM standards is also relevant here. While the basis for decisions on specific indicators is discussed more fully in Unit II.C. of this preamble, this issue is related to the Administrator's decision on the need to revise the standards. Based on both the staff review (U.S. EPA, 1996b, p. VII-3) and the recommendations of some commenters (e.g., California EPA), there are two alternative approaches for providing additional health protection in revising the standards: Adopt tighter PM_{10} standards and/or recognize the fundamental differences between fine and coarse particles and develop separate standards for the major components of PM_{10}, including fine particles. Conceptually, the first approach would give weight to comments that standards should be based on pollutant indicators for which the most data have been collected, with less consideration of the evidence that suggests that the current standards provide adequate protection against the effects of coarse particles, and that tightening the current PM_{10} standards in an attempt to control fine particles would place unnecessary requirements on coarse particles. Because the PM_{10} network is in place, a more stringent PM_{10} standard would also respond to commenters who have expressed a desire for more immediate implementation of revised standards. The second approach is based on the view that, in the long run, more effective and efficient protection can be provided by separately targeting appropriate levels of controls to fine and coarse PM.

The Staff Paper examined this issue in detail (U.S. EPA 1996b, pp. VII-3 to VII-11), and concluded that the available information was sufficient to develop separate indicators for fine and coarse fractions of PM_{10}, based on the recent health evidence, the fundamental differences between fine- and coarse-fraction particles, and implementation experience with PM_{10}. Further, the staff concluded that:

> [C]onsideration of comparisons between fine and coarse fractions suggests that fine fraction particles are a better surrogate for those particle components linked to mortality and morbidity effects at levels below the current standards. In contrast, coarse fraction particles are more likely linked with certain effects at levels above those allowed by the current PM_{10} standards. In examining alternative approaches to increasing the protection afforded by PM_{10} standards, the staff concludes that reducing the levels of the current PM_{10} standards would not provide the most effective and efficient protection from these health effects. [U.S. EPA 1996b; p. 7-45]

As discussed in Unit II.C. of this preamble, the Administrator believes that it is more appropriate to provide additional protection against the risk posed by PM by adding new standards for the fine fraction of PM_{10}, as opposed to tightening the current PM_{10} standards. Although fewer epidemiological studies have used $PM_{2.5}$ and other fine particle indicators (e.g., sulfates, acids), there are nonetheless significant indications from the scientific evidence - drawn from the physicochemical studies of PM, air quality and exposure information, toxicological studies, and respiratory tract deposition data - that this approach will provide the most effective and efficient protection of public health.

Several commenters have argued that the decision on whether to revise the PM standards should be deferred, particularly with regard to fine particle standards, pending establishment and operation of a national monitoring network to characterize fine PM and a research program to reduce uncertainties in the effects information. These commenters expressed concerns that establishing fine PM standards now might result in needless regulation of PM components that may be unrelated to observed health effects. As discussed more fully in Unit II.F. of this preamble, such commenters recommended, at most, that if fine PM standards were established, they should be set at a level ''equivalent'' to the current PM standards.

EPA strongly disagrees that the decision on revising the standards should be delayed to await the results of new PM monitoring and research programs. Under section 109(d) of the Act, EPA's obligation after reviewing the

existing criteria and standards for PM is to make such revisions in the standards and to promulgate such new standards as are appropriate under section 109(b) of the Act. Based on her review of the criteria and standards for PM, the Administrator has concluded that the current standards are not adequate to protect public health and that revisions are appropriate. In the face of the available evidence, a delay in revising the standards would not only be inconsistent with the statute but -- even under the optimistic assumption that the same extensive monitoring and strategy assessment as now contemplated would occur in the absence of a revised standard -- would add approximately 2 years to the time when significant health benefits can be realized, resulting in potentially significant numbers of additional premature deaths and even larger numbers of children and individuals with air pollution-related illness and symptoms. On the other hand, establishing standards now will set into motion the development of implementation programs and monitoring that can be conducted in parallel with additional scientific research, without undue delays inherent in waiting for the research.

The question of which pollutant components to regulate has been an issue since the inception of the first PM standards. Other ambient pollutants (e.g., NO_2 or CO) are uniquely defined as individual chemicals, whether or not they serve as proxies for a larger class of substances (e.g., ozone as an index of photochemical oxidants). Regulating general PM, as opposed to multiple chemical components of PM, raises the spectre of a host of particulate materials of varying composition, size, and other physicochemical properties, not all of which are likely to produce identical effects.

Both EPA's past and present regulatory experience with PM control programs and its successive reviews of the standards have reaffirmed the wisdom of retaining standards that control particles as a group, rather than eliminating such standards and waiting for scientific research to develop information needed to identify more precise limits for the literally thousands of particle components. Each such decision recognized the possibility that potentially less harmful particles might be included in the mix that was regulated, but concluded that the need to provide protection against serious health effects nonetheless required action under section 109 of the Act. The success of this approach is evident in early U.S. control programs that dramatically reduced ''smoke'' and ''TSP'' in major cities in the 1960's and 1970's and in the continued improvement in air quality through the current PM standards. The major refinements that have been recommended through the course of reviews of PM standards have been to improve the focus of control efforts by defining scientifically based size classes (i.e., moving from TSP to PM_{10} and now, $PM_{2.5}$) that will permit more effective and efficient regulation of those fractions most likely to present significant risks to health and the environment.

As discussed in Unit II.C. of this preamble, the current review has examined the available evidence to determine whether it would tend to support inclusion or exclusion of any physical or chemical classes of PM, for example sulfates, nitrates, or ultra-fine particles. That examination concludes that, while both fine and coarse particles can produce health effects, the fine fraction appears to contain more of the reactive substances potentially linked to the kinds of effects observed in the recent epidemiological studies (U.S. EPA 1996b, section V.F.). However, the available scientific information does not rule out any one of these components as contributing to fine particle effects. Indeed, it is reasonable to anticipate that no single component will prove to be responsible for all of the effects of PM.

EPA recognizes that whether the standards are set for PM_{10} only or also for fine particles, there are uncertainties with respect to the relative risk presented by various components of PM. In this regard, the Administrator places greater weight on the concern that by failing to act now, the PM NAAQS would not control adequately those components of air pollution that are most responsible for serious effects, than on the possibility they might also control some component that is not. EPA believes that moving simultaneously to establish standards based on the best available scientific evidence and to conduct an aggressive monitoring and scientific research program designed to help resolve current uncertainties is a prudent and responsible approach for addressing both the risks and the uncertainties inherent in this important public health issue.

In summary, given the evidence that PM-related health effects appear likely to occur at levels below the current standards, the serious nature and potential magnitude of the public health risks involved, and the need to consider the fine and coarse fractions as distinct classes of particles, the Staff Paper and the CASAC (Wolff, 1996b) concluded that revision of the current standards is clearly appropriate. Moreover, at their May 1996 public meeting (U.S. EPA, 1996c), and in separate written comments (including Lippmann et al., 1996), a majority of CASAC panel members recommended revisions that would strengthen the health protection provided by the current PM standards. Based on the rationale and recommendations contained in the Staff Paper and the advice of CASAC, and taking into account public comments, the Administrator concludes that it is appropriate at this time to revise the current PM standards to increase the public health protection provided against the known and potential effects of PM identified in the air quality criteria.

C. Indicators of PM

In establishing adequately protective, effective, and efficient PM standards, it is necessary to specify the fraction of particles found in the ambient air that should be used as the indicator(s) for the standards. In this regard, EPA concludes that the most recent assessment of scientific information in the Criteria Document, summarized in chapters IV and V of the Staff Paper, continues to support past staff and CASAC recommendations regarding the selection of size-specific indicators for PM standards. More specifically, EPA continues to find that the following conclusions reached in the Staff Paper and in the 1987 review remain valid:

(1) Health risks posed by inhaled particles are influenced both by the penetration and deposition of particles in the various regions of the respiratory tract and by the biological responses to these deposited materials.

(2) The risks of adverse health effects associated with deposition of ambient fine and coarse fraction particles in the thoracic (tracheobronchial and alveolar) regions of the respiratory tract are markedly greater than for deposition in the extrathoracic (head) region. Maximum particle penetration to the thoracic region occurs during oronasal or mouth breathing.

(3) The risks of adverse health effects from extrathoracic deposition of general ambient PM are sufficiently low that particles which deposit only in that region can safely be excluded from the standard indicator.

(4) The size-specific indicator(s) should represent those particles capable of penetrating to the thoracic region, including both the tracheobronchial and alveolar regions.

These conclusions, together with information on the dosimetry of particles in humans, were the basis for the promulgation in 1987 of a new size-specific indicator for the PM NAAQS, PM_{10}, that includes particles with an aerodynamic diameter smaller than or equal to a nominal 10 μm. The recent information on human particle dosimetry contained in the Criteria Document provides no basis for changing 10 μm as the appropriate cut point for particles capable of penetrating to the thoracic regions.

As noted in Unit II.B. of this preamble, however, the Staff Paper concludes that continued use of PM_{10} as the sole indicator for the PM standards would not provide the most effective and efficient protection from the health effects of PM (U.S. EPA, 1996b, pp. VII-4 to VII-11). Based on the recent health effects evidence and the fundamental physical and chemical differences between fine and coarse fraction particles, the Criteria Document and Staff Paper conclude that fine and coarse fractions of PM_{10} should be considered separately (U.S. EPA, 1996a, p. 13-93; 1996b, p. VII-18). Taking into account such information, CASAC found sufficient scientific and technical bases to support establishment of separate standards relating to these two fractions of PM_{10}. Specifically, CASAC advised the Administrator that ''there is a consensus that retaining an annual PM_{10} NAAQS * * * is reasonable at this time'' and that there is ''also a consensus that a new $PM_{2.5}$ NAAQS be established'' (Wolff, 1996b).

Some commenters have noted that it is often difficult to distinguish the effects of either fine or coarse fraction particles from those of PM_{10}; this is to be expected because both fractions are themselves components of PM_{10}, and hence not fully independent. EPA believes that it is more meaningful to examine comparisons between the fine and coarse fraction components. Such comparisons presented in the Staff Paper suggest that fine particles are a better surrogate for those components of PM that are linked to mortality and morbidity effects at levels below the current standards (U.S. EPA, 1996b, p. VII-18). Moreover, a regulatory focus on fine particles would likely also result in controls on gaseous precursors of fine particles (e.g., SO_x, NO_x, VOC), which are all components of the complex mixture of air pollution that has most generally been associated with mortality and morbidity effects. The Staff Paper concludes that, in contrast to fine particles, coarse fraction particles are more clearly linked with certain morbidity effects at levels above those allowed by the current 24-hour standard.

Public comments received on the proposed indicators were overwhelmingly in favor of EPA's proposal to maintain PM_{10} as an indicator for PM, whether as an indicator of coarse particles in conjunction with a fine PM standard, or as the sole PM indicator. This near unanimity shows strong support for retaining general PM standards. While a substantial number of commenters supported EPA's proposal to add an indicator for fine PM, a number of other commenters objected to any standard revisions, including addition of a fine PM indicator. Beyond the general points about the basis for any revisions discussed in Unit II.B. of this preamble, these commenters argued either that the available epidemiological data did not provide a basis for separating fine and coarse fraction particles, or that there were not enough fine particle studies to support selecting standard levels. Most of these commenters also expressed concerns that there were insufficient ambient fine particle data by which to evaluate the relative protection afforded by new standards.

EPA notes that issues relating to the basis for separating PM_{10} fractions were addressed in the Criteria Document and/or Staff Paper assessments, and these perspectives were also available for CASAC consideration in developing its recommendations. The proposal states that the main basis for separating the fine and coarse fractions of PM_{10} is that, because they are fundamentally different PM components with significantly different physico-chemical properties and origins (U.S. EPA 1996b, section V.D), separate standards would permit more effective and efficient regulation of PM. While the difficulty in separating these classes in the epidemiological studies is noted above, the preponderance of the available evidence suggests that strategies to control fine particles will more effectively reduce population exposure to substances associated with health effects in the recent epidemiological studies. Although the number of studies using fine PM indicators is more limited than for PM_{10}, there are more than 20 community studies showing significant associations for a consistent set of mortality and morbidity effects. A substantial subset of these studies (Tables V-12 to V-13; U.S. EPA, 1996b) provides a sufficient quantitative basis for selecting standard levels, without the need to rely on estimates based on $PM_{2.5}/PM_{10}$ ratios.

Having considered the public comments on this issue, the Administrator concurs with staff and CASAC recommendations to control particles of health concern (i.e., PM_{10}) through separate standards for fine and coarse fraction particles. The following units outline the basis for the Administrator's decision on specific indicators for fine and coarse fraction particle standards.

1. *Indicators for the fine fraction of* PM_{10}. The Administrator continues to conclude that it is appropriate to control fine particles as a group, as opposed to singling out particular components or classes of fine particles. The more qualitative scientific literature, evaluated in Chapter 11 of the Criteria Document and summarized in section V.C of the Staff Paper, has reported various health effects associated with high concentrations of a number of fine particle components (e.g., sulfates, nitrates, organics, transition metals), alone or in some cases in combination with gases. Community epidemiolgical studies have found significant associations between fine particles or PM_{10} and health effects in various areas across the U.S. where such fine particle components correlate significantly with particle mass. As noted above in this unit, it is not possible to rule out any one of these components as contributing to fine particle effects.[26] Thus, the Administrator finds that the present data more readily support a standard based on the total mass of fine particles. EPA will conduct additional research, in cooperation with other Federal agencies and in partnership with State and local agencies and the private sector, to better identify which species are of concern for human health, and the sources and relative magnitude of such species.

In specifying a precise size range for a fine particle standard, both the staff and CASAC recommended $PM_{2.5}$ as the indicator of fine particles (Wolff, 1996b). The particle diameter reflecting the mass minimum between the fine and coarse modes typically lies between 1 and 3 μm, and the scientific data support a sampling ''cut point'' to delineate fine particles somewhere in this range. Because of the potential

[26] As discussed above, a number of commenters expressed concerns that various portions of fine particles might not be responsible for any observed effects. One group (PG&E, 1997) recommended that nitrates should be excluded from fine PM mass collected on the basis of their assessment of available effects literature on particulate and gas phase inorganic nitrates. Based on an examination of this information as well as the earlier staff assessment, EPA maintains its conclusion that the available evidence is not sufficient to exclude nitrates or any other class of fine particles that are collected by PM monitors comparable to those used in the recent epidemiological studies.

overlap of fine and coarse particle mass in this intermodal region, EPA recognizes that any specific sampling cut point would result in only an approximation of the actual fine-mode particle mass. Thus, the choice of a specific diameter within this size range is largely a policy judgment. The staff and CASAC recommendations for a 2.5 μm sampling cut point were based on considerations of consistency with the community health studies, the limited potential for intrusion of coarse fraction particles into the fine fraction, and availability of monitoring technology.[27] $PM_{2.5}$ encompasses all of the potential agents of concern in the fine fraction, including most sulfates, acids, fine particle transition metals, organics, and ultrafine particles, and includes most of the aggregate surface area and particle number in the entire distribution of atmospheric particles.

The Administrator concurs with the staff and CASAC recommendations and concludes that $PM_{2.5}$ is the appropriate indicator for fine particle standards. As discussed in Unit VI.B. of this preamble, technical details of how $PM_{2.5}$ is to be measured in the ambient air are specified in the Federal Reference Method (40 CFR part 50, Appendix L).

2. *Indicators for the coarse fraction of* PM_{10}. The Criteria Document and Staff Paper conclude that epidemiological information, together with dosimetry and toxicological information, support the need for a particle indicator that addresses the health effects associated with coarse fraction particles within PM_{10} (i.e., $PM_{10-2.5}$). As noted above, coarse fraction particles can deposit in those sensitive regions of the lung of most concern. Although the role of coarse fraction particles in much of the recent epidemiological results is unclear, limited evidence from studies where coarse fraction particles are the dominant fraction of PM_{10} suggest that significant short-term effects related to coarse fraction particles include aggravation of asthma and increased upper respiratory illness. In addition, qualitative evidence suggests that potential chronic effects may be associated with long-term exposure to high concentrations of coarse fraction particles.

In selecting an indicator for coarse fraction particles, the Administrator took into account the views of several CASAC panel members who suggested using the coarse fraction directly (i.e., $PM_{10-2.5}$) as the indicator. However, the Administrator notes that the existing ambient data base for coarse fraction particles is smaller than that for fine particles, and that the only studies of clear quantitative relevance to effects most likely associated with coarse fraction particles have used undifferentiated PM_{10}. In fact, it was the consensus of CASAC that it is reasonable to consider PM_{10} itself as a surrogate for coarse fraction particles, when used together with $PM_{2.5}$ standards. The monitoring network already in place for PM_{10} is large. Therefore, in conjunction with the decision to have separate standards for $PM_{2.5}$, the Administrator concludes, consistent with CASAC recommendations and public comments, that it is appropriate to retain PM_{10} as the indicator for PM standards intended to protect against the effects most likely associated with coarse fraction particles.

D. Averaging Time of $PM_{2.5}$ Standards

As discussed above in this unit, the Administrator has concluded that $PM_{2.5}$ is an appropriate indicator for standards intended to provide protection from effects associated primarily with fine particles. The recent health effects information includes reported associations with both short-term (from less than 1 day to up to 5 days) and long-term (from a year to several years) measures of PM.

On the basis of this information, summarized in chapter V of the Staff Paper and in the rationale presented in the proposal, the Administrator has considered both short- and long-term $PM_{2.5}$ standards.

1. *Short-term $PM_{2.5}$ standard.* The current 24-hour averaging time is consistent with the majority of community epidemiological studies, which have reported associations of health effects with 24-hour concentrations of various PM indicators such as PM_{10}, fine particles, and TSP. Such health effects, including premature mortality and increased hospital admissions, have generally been reported with same-day, previous day, or longer lagged single-day concentrations, although some studies have reported stronger associations with multiple-day average concentrations. In any case, the Administrator recognizes that a 24-hour $PM_{2.5}$ standard can effectively protect against episodes lasting several days, since attainment of such a standard would provide protection on each day of a multi-day episode, while also protecting sensitive individuals who may experience effects after even a single day of exposure.

Although most reported effects have been associated with daily or longer measures of PM, evidence also suggests that some effects may be associated with PM exposures of shorter durations. For example, controlled human and animal exposures to specific components of fine particles, such as acid aerosols, suggest that bronchoconstriction can occur after exposures of minutes to hours. Some epidemiological studies of exposures to acid aerosols have also found changes in respiratory symptoms in children using averaging times less than 24 hours. However, such reported results do not provide a satisfactory quantitative basis for setting a fine particle standard with an averaging time of less than 24 hours, nor do current gravimetric mass monitoring devices make such shorter durations generally practical at present. Further, the Administrator recognizes that a 24-hour average $PM_{2.5}$ standard which leads to reductions in 24-hour average concentrations is likely to lead as well to reductions in shorter-term average concentrations in most urban atmospheres, thus providing some degree of protection from potential effects associated with shorter duration exposures.

2. *Long-term $PM_{2.5}$ standard.* Community epidemiological studies have reported associations of annual and multi-year average concentrations of PM_{10}, $PM_{2.5}$, sulfates, and TSP with an array of health effects, notably premature mortality, increased respiratory symptoms and illness (e.g., bronchitis and cough in children), and reduced lung function. The relative risks associated with such measures of long-term exposures, although highly uncertain, appear to be larger than those associated with short-term exposures. Based on the available epidemiology, and consistent with the limited relevant toxicological and dosimetric information, the Administrator concludes that significant, and potentially independent, health consequences are likely associated with long-term PM exposures.

[27] The National Mining Association (NMA) and related companies submitted comments favoring ultimate selection of a smaller cutpoint of 1 μm (PM_1) to further reduce coarse particle intrusion. EPA considered this approach in developing the Staff Paper and proposal. PM_1 has not been used in health studies, although in most cases collected mass should be similar to those for cutpoints of 2.1 or 2.5 μm. While a PM_1 indicator could reduce intrusion of coarse particles, it might also omit portions of hygroscopic PM components such as acid sulfates, nitrates, and some organic compounds in higher humidity environments picked up by $PM_{2.5}$ measurements. PM_1 sampling technologies have been developed, but have not been widely used in the field to date; there are some concerns about loss of certain organic materials in available models relative to an instrument with a larger size cut. NMA has also recommended consideration of a methodology that could subtract coarse mass from $PM_{2.5}$ measurements where undue coarse particle intrusion resulted in fine standard violations. EPA will evaluate this recommendation in the context of implementation policies.

The Administrator has considered this evidence, which suggests that some health endpoints reflect the cumulative effects of PM exposures over a number of years. In such cases, an annual standard would provide effective protection against persistent long-term (several years) exposures to PM. Requiring a much longer averaging time would also complicate and unnecessarily delay control strategies and attainment decisions.

The Administrator has also considered the seasonality of emissions of fine particles and their precursors in some areas (e.g., wintertime smoke from residential wood combustion, summertime regional acid sulfate and ozone formation), which suggests that some effects associated with annual average concentrations might be the result of repeated seasonally high exposures. However, different seasons are likely of concern in different parts of the country, and the current evidence does not provide a satisfactory quantitative basis for setting a national fine particle standard in terms of a seasonal averaging time.

In addition, the Administrator recognizes that an annual standard would have the effect of improving air quality broadly across the entire annual distribution of 24-hour $PM_{2.5}$ concentrations, although such a standard would not as effectively limit peak 24-hour concentrations as would a 24-hour standard. The risk assessment summarized above found that because such 24-hour peaks contribute much less to the total health risk over a year than the more numerous low- to mid-range $PM_{2.5}$ levels, an annual standard could also provide effective protection from health effects associated with short-term exposures to $PM_{2.5}$ as well as those associated with long-term exposures (see figure 2; 61 FR 65652-65653, December 13, 1996).

3. *Combined effect of annual and 24-hour standards.* For the reasons outlined in Units II.C.1. and 2. of this preamble, the Administrator concluded in the proposal that a short-term $PM_{2.5}$ standard with a 24-hour averaging time can serve to control short-term ambient $PM_{2.5}$ concentrations, thus providing protection from health effects associated with short-term (from less than 1-day to up to 5-day) exposures to $PM_{2.5}$. Further, a long-term $PM_{2.5}$ standard with an annual averaging time can serve to control both long- and short-term ambient $PM_{2.5}$ concentrations, thus providing protection from health effects associated with long-term (seasonal to several years) and, to some degree, short-term exposures to $PM_{2.5}$.

EPA received comparatively few public comments on these proposed averaging times. Those supporting $PM_{2.5}$ standards also strongly supported adopting both annual and 24-hour averaging times. Many of those opposing $PM_{2.5}$ standards, for the reasons discussed in Unit II.B. of this preamble, provided contingent comments that variously supported both averaging times for $PM_{2.5}$ standards in the event the Administrator disagreed with their overall recommendations. Other opponents of $PM_{2.5}$ standards disagreed with having two standards on administrative grounds, or because some CASAC members did not support both averaging times.

The relationship between standards for the two averaging times is discussed below in this unit. In essence, based on its examination of the effects data and air quality relationships, EPA believes that a single $PM_{2.5}$ standard (24-hour or annual) either would not provide adequate protection against effects of concern for all averaging times, or would be inefficient in the sense that it was more stringent than necessary for at least one averaging time. Contrary to commenters who focused on minority CASAC opinions, EPA notes that a clear majority of CASAC supported both 24-hour and annual standards[28]. After considering public comments on averaging time and the rationale outlined above, the Administrator has concluded that both 24-hour and annual $PM_{2.5}$ standards are appropriate.

The Administrator next considered the potential combined effects of such standards on PM concentration levels and distributions. The existing health effects evidence could, of course, be used to assess the form and level of each standard independently, with short-term exposure health effects evidence being used as the basis for a 24-hour standard and the long-term exposure health effects evidence as the entire basis for an annual standard. Some CASAC panel members apparently used this approach as a basis for their views on appropriate averaging times and standard levels. In particular, a few members focused only on a 24-hour $PM_{2.5}$ standard in light of the relative strength of the short-term exposure studies. On the other hand, two members focused only on an annual standard, recognizing that strategies to meet an annual standard would provide protection against effects of both short- and long-term exposures.

[28] Of the 19 panel members who joined in the consensus for $PM_{2.5}$ standards, 17 (90 percent) recommended a 24-hour standard and 13 (70 percent) recommended an annual standard (Wolff, 1996b).

As noted above in this unit, attempting to provide protection for all of the effects identified in long- and short-term PM exposure studies with a single averaging time would result in either inadequate protection for some effects, or unnecessarily stringent control for others. The Administrator has, instead, emphasized a policy approach that considers the consistency and coherence, as well as the limitations, of the body of evidence as a whole, and recognizes that there are various ways to combine two standards to achieve an appropriate degree of public health protection. Such an approach to standard setting, which integrates the body of health effects evidence and air quality analyses, and considers the combined effect of the standards, has the potential to result in a more effective and efficient suite of standards than an approach that only considers short- and long-term exposure evidence, analyses, and standards independently.

In considering the combined effect of such standards, the Administrator notes that while an annual standard would focus control programs on annual average $PM_{2.5}$ concentrations, it would also result in fewer and lower 24-hour peak concentrations. Alternatively, a 24-hour standard that focuses controls on peak concentrations could also result in lower annual average concentrations. Thus, either standard could be viewed as providing both short- and long-term protection, with the other standard serving to address situations where the daily peaks and annual averages are not consistently correlated.

The Administrator proposed that the suite of $PM_{2.5}$ standards could most effectively and efficiently be defined by treating the annual standard as the generally controlling standard for lowering both short- and long-term $PM_{2.5}$ concentrations. In conjunction with the annual standard, the 24-hour standard would serve to provide protection against days with high peak $PM_{2.5}$ concentrations, localized ''hot spots,'' and risks arising from seasonal emissions that would not be well controlled by a national annual standard.

Relatively few public comments were addressed specifically to the proposal that the annual standard be directed toward controlling both 24-hour and annual levels (thereby basing the annual standard on an evaluation of both the short- and long-term health effects information), with the 24-hour standard being used to address more localized short-term peaks. A number of commenters, notably some among the groups opposing any revised PM

standards, appeared to have ignored this fundamental aspect of the proposal, judging by their assertions that the sole basis for EPA's proposed annual standards was two long-term exposure studies (Dockery et al., 1993; Pope et al. 1995). This is incorrect; as the proposal states, EPA based the proposed annual standard level on a wider range of short- and long-term exposure studies. Other commenters, including some environmental groups, reserved comment on this specific issue, but expressed concerns that the specific levels for both standards were not stringent enough, regardless of which standard is intended to be controlling. Issues regarding specific levels are discussed below in Unit II.F. of this preamble.

Some commenters, however, disagreed with the proposition that EPA's proposed approach would necessarily provide the most effective and efficient standards. In the view of some who opposed $PM_{2.5}$ standards, the likelihood that there are thresholds below which no effects occur means that a 24-hour standard would be more efficient than an annual standard. In this view, the reductions made on days that were below the threshold would provide no protection.[29] Some commenters also noted that while a majority of CASAC members favored both annual and 24-hour standards, more recommended 24-hour standards.

While the available epidemiological studies provide strong evidence suggesting that PM causes or contributes to health effects at levels below the current standards, EPA agrees, as stated previously, that uncertainties increase markedly at lower concentrations. Nevertheless, the level or even existence of population thresholds below which no effects occur cannot be reliably determined by an examination of the results from the available studies. Analyses have placed some limits, however, and EPA has considered hypothetical thresholds in its risk assessment. As noted in Unit II.A. of this preamble, even assuming an example threshold of 18 $\mu g/m^3$, the risk assessment (see Figure 2c; 61 FR 65653, December 13, 1996) finds that most of the annual aggregate risk associated with short-term exposures still results from the large number of days at lower to mid-range values above the mean. Given that neither the Criteria Document nor commenters have provided quantitative evidence regarding the likelihood of a threshold at levels much higher than the above example, EPA believes that the evidence provided in the risk assessment does not support the commenters' position. As noted above, EPA believes that most CASAC opinions on averaging time reflect panelists' judgments on the relative strength of the short-term exposure epidemiological studies, a judgment that EPA shares. Although most CASAC panel members did not offer an opinion on the use of short-term exposure studies in specifying annual standards, two panelists did support this notion. EPA therefore believes this approach is neither inconsistent with the underlying science nor discordant with the advice of CASAC.

Another concern was raised by some air pollution control officials who otherwise supported revised PM standards. These commenters state that, from an implementation perspective, it is often easier to design control strategies for single short-term events than for annual averages. Aside from whether this is a proper consideration in establishing NAAQS, the point in fact highlights one of the important strengths of an annual standard in addressing short-term risks associated with $PM_{2.5}$. As noted by the commenters, risk management for a short-term standard focuses on a characteristic ''design value'' episode responsible for peak concentrations. For PM, such peak values can be associated with single source contributions. Meteorology, relative source contributions, and resulting particle composition for that day may or may not be typical for the area or for the year. Yet the short-term exposure epidemiological results are largely drawn from studies that associated variations in area-wide effects with monitor(s) that gauged the variation in daily levels over the course of up to 8 years. The strength of the associations in these data is demonstrably in the numerous ''typical'' days in the upper to middle portion of the annual distribution, not on the peak days.[30] For these reasons, strategies that focus only on reducing peak days are less likely to achieve reduction of the mix and sources of urban and regional-scale PM pollution most strongly associated with health effects. Although designing control strategies to reduce annual levels may be more difficult than for 24-hour standards, the available short- and long-term epidemiological data suggest it is also likely to result in a greater reduction in area-wide population exposure and risk.

The Administrator concludes that the most effective and efficient approach to establishing $PM_{2.5}$ standards is to treat the annual standard as the generally controlling standard for lowering both short- and long-term $PM_{2.5}$ concentrations, while the 24-hour standard would serve to provide protection against days with high peak $PM_{2.5}$ concentrations, localized ''hot spots,'' and risks arising from seasonal emissions that would not be well controlled by a national annual standard. In reaching this view, the Administrator took into account the public comments and the factors discussed below in this unit.

(1) Based on one of the key observations from the quantitative risk assessment summarized above (see Figures 2a,b,c; 61 FR 65652-65653, December 13, 1996), the Administrator notes that much if not most of the aggregate annual risk associated with short-term exposures results from the large number of days during which the 24-hour average concentrations are in the low- to mid-range, below the peak 24-hour concentrations. As a result, lowering a wide range of ambient 24-hour $PM_{2.5}$ concentrations, as opposed to focusing on control of peak 24-hour concentrations, is the most effective and efficient way to reduce total population risk. Further, there is no evidence suggesting that risks associated with long-term exposures are likely to be disproportionately driven by peak 24-hour concentrations. Thus, an annual standard that controls an area's attainment status is likely to reduce aggregate risks associated with both short- and long-term exposures with more certainty than a 24-hour standard.

(2) The consistency and coherence of the health effects data base are, therefore, more directly related to the more frequently occurring PM exposures reflected in study period mean measures of air quality (e.g., the annual distributions of 24-hour PM concentrations), than to the potentially site-specific and/or otherwise infrequent PM exposures reflected in a limited number of peak 24-hour concentrations. More specifically, judgments about the quantitative consistency of the large number of short-term exposure studies

[29] A related comment criticized the risk assessment conclusion that peak 24-hour concentrations contribute much less to the total risk over a year as inconsistent with the experience in historic air pollution episodes. EPA disagrees. While the historic London episodes were quantitatively different from those assumed in the risk assessment, the record over 14 London winters indicates a continuum of effects down to the lowest levels. It is therefore likely that the cumulative increase in mortality calculated for all the days in the whole 14-year period would not be dominated by the more limited number of episode days.

[30] This point is buttressed by studies that have taken out a limited number of higher PM concentration days with little effect on the effects estimates or significance of the association (e.g., Schwartz et al., 1996; Pope and Dockery, 1992).

reporting associations with 24-hour concentrations arise from comparing the relative risk results per PM increment as derived from analyzing the associations across the entire duration of the studies. These studies typically spanned at least an annual time frame and the reported associations are most strongly influenced by the large number of days toward the middle of the distribution.

(3) An annual average measure of air quality is more stable over time than are 24-hour measures. Thus, a controlling annual standard is likely to result in the development of more consistent risk reduction strategies over time, since an area's attainment status will be less likely to change due solely to year-to-year variations in meteorological conditions that affect the formation of fine particles, than under a controlling 24-hour standard.

Under this policy approach, the annual $PM_{2.5}$ standard would serve in most areas as the target for control programs designed to be effective in lowering the broad distribution of $PM_{2.5}$ concentrations, thus protecting not only against long-term effects but also short-term effects as well. In combination with such an annual standard, the 24-hour $PM_{2.5}$ standard would be set so as to protect against the occurrence of peak 24-hour concentrations, particularly peak concentrations that present localized or seasonal exposures of concern in areas where the highest 24-hour-to-annual mean $PM_{2.5}$ ratios are appreciably above the national average.

E. Form of $PM_{2.5}$ Standards

1. *Annual standard.* As discussed in some detail during the last review of the PM NAAQS (see 49 FR 10408, March 20, 1984; 52 FR 24634, July 1, 1987) and in the December 13, 1996 proposal, the annual arithmetic mean form of the current annual PM_{10} standard (i.e., the annual arithmetic mean averaged over 3 years) is a relatively stable measure of air quality that reflects the total cumulative dose of PM to which an individual or population is exposed. Short-term peaks have an influence on the arithmetic mean that is proportional to their frequency, magnitude, and duration, and, thus, their contribution to cumulative exposure and risk. As a result, the annual arithmetic mean form of an annual standard provides protection across a wide range of the air quality distribution contributing to exposure and risk, in contrast to other forms, such as the geometric mean, that de-emphasize the effects of short-term peak concentrations.

While almost no commenters took specific issue with use of an annual arithmetic mean, a number of commenters disagreed with averaging over 3 years for both the annual and 24-hour standards because of their desire for quick action in the initial implementation of $PM_{2.5}$ controls. The Administrator recognizes the importance of promptly implementing appropriate control programs, but she does not believe that implementation start-up concerns are an adequate basis for adopting a form (e.g., a single year annual average) that would provide less stable risk reduction in the long-run. Therefore, the Administrator continues to concur with the Staff Paper recommendation, supported by CASAC, to use the annual arithmetic mean, averaged over 3 years, as the form for an annual $PM_{2.5}$ standard consistent with the current form of the annual PM_{10} standard. Nevertheless, EPA intends to address the concerns of those who commented that the 3-year form might prevent the public from being informed about the air quality status of their communities. As outlined in Unit II.H. of this preamble, EPA plans to issue revised Pollutant Standard Index criteria for $PM_{2.5}$, to ensure the public is informed promptly about air quality status.

The Staff Paper and some CASAC panel members also recommended that consideration be given to calculating the $PM_{2.5}$ annual arithmetic mean for an area by averaging the annual arithmetic means derived from multiple monitoring sites within a monitoring planning area. In proposing a calculation method for annual arithmetic averages that involves spatial averaging of monitoring data, the Administrator reasoned as follows:

(1) Many of the community-based epidemiological studies examined in this review used spatial averages, when multiple monitoring sites were available, to characterize area-wide PM exposure levels and the associated population health risk. In those studies that used only one monitoring location, the selected site was chosen to represent community-wide exposures, not the highest value likely to be experienced within the community. Thus, spatial averages are most directly related to the epidemiological studies used as the basis for the proposed revisions to the PM NAAQS.

(2) As a part of the overall policy approach discussed in Unit II.D. of this preamble, the annual $PM_{2.5}$ standard would be intended to reduce aggregate population risk from both long- and short-term exposures by lowering the broad distribution of $PM_{2.5}$ concentrations across the community. An annual standard based on spatially averaged concentrations would better reflect area-wide PM exposure levels than would a standard based on concentrations from a single monitor with the highest measured values.

(3) Under this policy approach, the 24-hour $PM_{2.5}$ standard would be intended to work in conjunction with a spatially averaged annual $PM_{2.5}$ standard by providing protection against peak 24-hour concentrations, localized ''hot spots,'' and higher $PM_{2.5}$ concentrations arising from seasonal emissions and meteorology that would not be as well controlled by an annual standard. Accordingly, the 24-hour $PM_{2.5}$ standard should be based on the single population-oriented monitoring site within the monitoring planning area with the highest measured values.

Based on these considerations, the Administrator proposed that the form of an annual $PM_{2.5}$ standard be expressed as the annual arithmetic mean, temporally averaged over 3 years and spatially averaged over all designated monitoring sites,[31] which, in conjunction with a 24-hour $PM_{2.5}$ standard, was intended to provide the most appropriate target for reducing area-wide population exposure to fine particle pollution. Recognizing the complexities that spatial averaging might introduce into risk management programs, in the proposal the Administrator also requested comment on the alternative of basing the annual standard for $PM_{2.5}$ solely on the single population-oriented monitor site within the monitoring planning area with the highest 3-year average annual mean.

The proposed approach to designating sites that are appropriate for spatial averaging was based on criteria and constraints contained in the proposed revision to the monitoring siting and network planning requirements in 40 CFR part 58. In proposing this approach, the Administrator noted concerns regarding the development and implementation of appropriate and effective criteria for the selection of sites and designations of areas for spatial averaging.

A number of commenters who otherwise favored setting $PM_{2.5}$ standards objected to the concept of population-oriented monitors and expressed the view that any monitor regardless of where it was sited should be eligible for comparison to the annual $PM_{2.5}$ standard. They further maintained that the proposed provisions for spatial averaging would fail to provide adequate health protection because

[31] The notice of proposed revisions to 40 CFR part 58 recognized that a single appropriately sited monitor could suffice for an area in place of an average of multiple monitors.

''clean areas'' and ''dirty areas'' would be averaged together. Some commenters expressed concern that the proposed constraints on spatial average would not be sufficient to prevent use of such averaging to avoid pollution abatement. Others may not have fully understood the implications of the specific constraints and siting requirements discussed in the proposed revisions to 40 CFR part 58, which were intended to ensure that the population-oriented monitors used for the annual standard were actually reflective of community-wide exposures and that the spatial averages did not include non-representative monitored values from either ''clean areas'' or ''dirty areas.''[32] In order to clarify the intent that the spatially averaged annual standard protect those in smaller communities, as well as those in larger population centers, the final revisions to 40 CFR part 58 adopt the term ''community-oriented'' monitors.

Other commenters, who supported $PM_{2.5}$ annual standards, endorsed the concept of spatial averaging as being more reflective of the air quality data used in the underlying health studies and because there is general uniformity of fine particle concentrations across an area. Opponents of the $PM_{2.5}$ standards expressed contingent support for spatial averaging in concept, again citing the linkage to the underlying health studies. Indeed, they advocated the extension of spatial averaging to the daily form of the standard, and/or recommended less constrained spatial averaging to allow for averaging across entire metropolitan areas.

The Administrator, of course, shares commenters' concerns that the form of the standards, in conjunction with other components of the standards, must protect public health adequately against risks associated with PM. It was for this reason that EPA proposed a policy approach providing for greatest overall risk reduction for all citizens in the community from exposures to the mix of urban and regional scale PM pollution most strongly associated with health effects. In specifically considering whether to allow for the use of spatial averaging, the Administrator placed great weight on consistency with the underlying body of health effects evidence. The Administrator is mindful that some community studies relied inherently on exposure and effects estimates that reflect comparatively broad spatial scales, as highlighted by those commenters desiring to extend permissible averaging; however, this type of exposure characterization may not be appropriate for all circumstances and might leave some areas without adequate protection.[33]

For these reasons, the 40 CFR part 58 proposal package contained criteria and constraints on spatial averaging. These criteria and constraints were intended to ensure that spatial averaging would not result in inequities in the level of protection provided by the PM standards. The Administrator again recognizes that either a single properly sited community-oriented monitor, or an average of more than one such monitors, are both appropriate indices of area-wide population exposures. Both are consistent with monitoring approaches used in community epidemiological studies upon which the standards are based. On the other hand, comparing the annual $PM_{2.5}$ standard to the maximum concentrations at a site that is not representative of community exposures, as some have suggested, would be inconsistent with the Administrator's goal of using the annual standard to reduce urban and regional scale exposures and risks. Further, the Administrator believes that the criteria and, siting requirements contained in 40 CFR part 58, provide adequate safeguards against inappropriate application of spatial averaging. Therefore, the Administrator continues to believe that an annual $PM_{2.5}$ standard reflective of area-wide exposures, in conjunction with a 24-hour standard designed to provide adequate protection against localized peak or seasonal $PM_{2.5}$ levels, reflects the most appropriate approach for public health against the effects of PM reported in the scientific literature.[34]

The majority of comments from States stressed the need for flexibility in specifying network designs and spatial averaging, given that the nature and sources of particle pollution vary from one area to another. One State agency specifically requested the flexibility to choose whether to use a single community-oriented monitor or a spatial average of several of such monitors, arguing that it is appropriate to provide this flexibility as $PM_{2.5}$ monitoring networks evolve and to address the diversity of local conditions.

As a result of EPA's evaluation of these comments, the requirements of 40 CFR part 50, Appendix K, and 40 CFR part 58 have been revised to clarify that the implementing agencies have the flexibility to compare the annual $PM_{2.5}$ standard either to the measured value at a single representative community-oriented monitoring site, or to the value resulting from an average of community-oriented monitoring sites that meet the revised criteria and constraints enumerated in the 40 CFR part 58 final rule.

In the Administrator's view, the final criteria and siting requirements contained in 40 CFR part 58 and in the new 40 CFR part 50, Appendix N, address the concerns raised by these commenters about the protection afforded by the form of the annual standard. Therefore, the Administrator continues to believe that the form of a $PM_{2.5}$ annual standard should be expressed as an annual arithmetic mean, averaged over 3 years, from single or multiple community-oriented monitors, in accordance with 40 CFR part 50, Appendix N and 40 CFR part 58. In her judgment, an annual standard expressed in this manner and set at an appropriate level, in conjunction with a 24-hour $PM_{2.5}$ standard, will adequately protect public health.

2. *24-hour standard.* The current 24-hour PM_{10} standard is expressed in a ''1-expected-exceedance'' form. That is, the standard is formulated on the basis of the expected number of days per year (averaged over 3 years) on which the level of the standard will be exceeded. The test for determining attainment of the current 24-hour standard is presented in Appendix K to 40 CFR part 50.

As discussed in the proposal, since promulgation of the current 24-hour PM_{10} standard in 1987, a number of concerns have been raised about the 1-

[32] The 40 CFR part 58 proposed rule identified the proposed criteria for monitors to be averaged; namely, monitors must be properly sited to reflect population-orientation, primarily influenced by similar sources, and within +/-20 percent of the average levels and a specific degree of correlation (or meet a ''homogeneity'' constraint). Additional criteria include demonstrations that the monitors to be averaged are influenced primarily by similar sources (e.g., to prevent the placement of monitors upwind in unrepresentative locations), EPA oversight of the monitoring program which includes regular review and approval of the State PM monitoring network design, and other criteria to ensure proper monitor siting. The final rule includes the addition of provisions that the State PM monitoring network design be available for public inspection.

[33] Daily mortality studies generally use urban or metro-areawide effects statistics in conjunction with single or multiple monitors that index day-to-day pollution changes across the area. Ito et al. (1995) found that spatial averages from multiple PM monitors in Chicago were better correlated with daily mortality than were most single monitors, but that single monitors were also associated. A number of morbidity studies (e.g., Schwartz et al., 1994; Neas et al., 1995; Raizenne et al.; 1996) used community scale monitors and effects information from a defined group of subjects from the community, who were more closely represented by the monitor.

[34] Because the 24-hour standard is designed to address localized peaks, it would be inappropriate to extend spatial averaging forms to this standard.

expected-exceedance form. These include, in particular, the year-to-year stability of the number of exceedances, the stability of the attainment status of an area, and the complex data handling conventions specified in 40 CFR part 50, Appendix K, including the procedures for making adjustments for missing data and less-than-every-day monitoring.

In light of these concerns, the Staff Paper and several CASAC panel members (Wolff, 1996b) recommended that consideration be given to adoption of a more stable and robust form for 24-hour standards. In considering this recommendation for the proposal, the Administrator noted that the use of a concentration-based percentile form would have several advantages over the current 1-expected-exceedance form:

(1) Such a concentration-based form would be more directly related to the ambient PM concentrations that are associated with health effects. Given that there is a continuum of effects associated with exposures to varying levels of PM, the extent to which public health is affected by exposure to ambient PM is related to the actual magnitude of the concentration, not just whether the concentration is above a specified level. With an exceedance-based form, days on which the ambient concentration is well above the level of the standard are given equal weight to those days on which the concentration is just above the standard (i.e., each day is counted as one exceedance), even though the public health impact on the 2 days is significantly different. With a concentration-based form, days on which higher concentrations occur would weigh proportionally more than days with lower concentrations for the design value, since the actual concentrations would be used directly in determining whether the standard is attained.

(2) A concentration-based percentile form would also compensate for missing data and less-than-every-day monitoring, thereby reducing or eliminating the need for complex data handling procedures in the 40 CFR part 50, Appendix K test for attainment. As a result, an area's attainment status would be based directly on monitoring data rather than on a calculated value adjusted for missing data or less-than-every-day monitoring.

(3) Further, a concentration-based form, averaged over 3 years, would also have greater stability than the expected exceedance form and, thus, would facilitate the development of more stable implementation programs by the States.

The proposal discussed various specific percentile values for such a form (e.g., 90th to 99th percentiles), taking into account two factors. First, the 24-hour $PM_{2.5}$ standard is intended to supplement the annual $PM_{2.5}$ standard by providing additional protection against extremely high peak days, localized ''hot spots,'' and risks arising from seasonal emissions. Second, given an appropriate level of health protection, the form of the 24-hour $PM_{2.5}$ standard should provide an appropriate degree of increased stability relative to the current form. The Administrator noted in the proposal that a more stable statistic would reduce the impact of a single high exposure event that may be due to unusual meteorological conditions alone, and thus would provide a more stable basis upon which to design effective control programs.

With these purposes in mind, the Administrator observed in the proposal that while a percentile value such as the 90th or 95th would provide substantially increased stability when compared to a more extreme air quality statistic (e.g., the current 1-expected-exceedance form), it would likely not serve as an effective supplement to the annual standard, because it would allow a large number of days with peak $PM_{2.5}$ concentrations above the standard level. For example, in a 365-day data base, the 90th and 95th percentiles would equal the 37th and 19th highest 24-hour concentrations, respectively. On the other hand, a percentile value selected much closer to the tail of the air quality distribution (e.g. a 99th or greater percentile) would not likely provide significantly more health protection or significantly increased stability as compared to a 1-exceedance form. In balancing these issues in the proposal, the Administrator ultimately proposed a 98th percentile value form of the standard.

Some commenters maintained that EPA should retain the current 1-expected-exceedance form for the 24-hour $PM_{2.5}$ standard to limit the number of days per year that the standard is exceeded. These commenters apparently gave little weight to EPA's rationale that a concentration-based form is more directly related to ambient PM concentrations that are associated with health effects because it takes into account the magnitude of PM concentrations, not just whether the concentrations are above a specific level. These commenters also discounted the other advantages of a concentration-based percentile form outlined above in this unit. A number of other commenters supported the concentration-based percentile form for the reasons outlined in the proposal but, as discussed below in this unit, argued for alternative percentile values that were higher or lower than the proposed 98th percentile value.

EPA continues to believe that a concentration-based percentile form is more reflective of the health risk posed by elevated PM concentrations, because it gives proportionally greater weight to days when concentrations are well above the level of the standard than to days when the concentrations are just above the standard. This factor, coupled with the other advantages outlined above in this unit, leads EPA to conclude that a concentration-based percentile form will provide for more effective health protection than a 1-expected-exceedance form.

Some commenters supporting a single exceedance form or a more restrictive concentration-based percentile form (e.g. a 99th percentile) expressed concern that the proposed 98th percentile form could allow too many high concentration excursions, and thus fail to provide adequate protection against seasonal emissions problems or localized peaks. In particular, some commenters expressed concerns that in areas with strongly seasonal emissions, such as western areas with winter inversions, over a three year period an area could experience several excursions in which levels could reach as high as 250 $\mu g/m^3$ and still comply with both the annual and daily standards if the remainder of the days had low levels (e.g., 10 $\mu g/m^3$). Although this combination of events is theoretically possible, EPA believes it is unlikely. Moreover, if such episodic events did occur, the Act provides for emergency State or Federal action to address them.[35] In view of the limits on truely episodic peak concentrations, EPA believes that an appropriately selected 24-hour standard with a concentration-based 98th percentile form can provide a stable and adequately protective supplement to the annual standard in areas with periodic peak concentrations.

Other commenters who were also concerned with monitoring requirements associated with spatial averaging in the annual standard, argued that a 98th percentile form, coupled with the proposed monitoring requirements that would limit

[35] See sections 303, 110(a)(2)(y); 40 CFR part 51. EPA intends to establish a significant harm level for $PM_{2.5}$ and associated guidance so States can develop appropriate emergency episode plans. The significant harm and episode criteria will be included in forthcoming proposed revisions to 40 CFR part 51 and 40 CFR part 58 implementation guidance. In the interim, existing PM_{10} emergency episode plans should be triggered by events of this magnitude.

compliance monitors for the 24-hour standard to population-oriented sites, would not protect people residing in or near localized ''hot spots'' in some areas.[36] The Administrator believes that the siting requirements as proposed and finalized in 40 CFR part 58 for population-oriented sites will provide adequate safeguards for such residential areas.

Other commenters, who otherwise opposed setting $PM_{2.5}$ standards, recommended that alternative lower percentiles (e.g., 95th percentiles) be used, if EPA proceeds to set such standards. As discussed above in this unit, however, EPA continues to hold the view that a 90th to 95th percentile form would not provide an adequate limit against periodic peak values in areas with low annual values and periodic high seasonal or source-oriented peaks.

After carefully assessing the comments received, the Administrator is persuaded that the adoption of a 98th percentile form for the 24-hour $PM_{2.5}$ standard measured at each population-oriented monitoring site in an area would provide an effective supplement to the annual $PM_{2.5}$ standard. This form will provide adequate protection against 24-hour peak $PM_{2.5}$ levels in locations dominated by single point sources, as well as in areas dominated by seasonal emissions. The Administrator also believes that a 98th percentile form, with more frequent sampling and averaged over 3 years, will provide increased stability and robustness as recommended by several members of the CASAC panel. For these reasons, the Administrator has decided to adopt the 98th percentile form for the final $PM_{2.5}$ 24-hour standard. The 24-hour $PM_{2.5}$ standard would be attained when the 3-year average of the 98th percentile of 24-hour concentrations at each populated oriented monitor within an area is less than or equal to the level of the standard. Further details regarding the interpretation of the form, as well as associated calculations and other data handling conventions are specified in the new 40 CFR part 50, Appendix N.

F. Levels for the Annual and 24-Hour $PM_{2.5}$ Standards

As discussed in Unit II.D. of this preamble, the Administrator believes that an annual $PM_{2.5}$ standard can provide the requisite reduction in risk associated with both annual and 24-hour averaging times in most areas of the United States. Under this approach, the 24-hour standard would be intended to provide supplemental protection against extreme peak fine particle levels that may occur in some localized situations or in areas with distinct variations in seasonal fine particle levels. In reaching judgments as to appropriate levels to propose for both the annual and 24-hour $PM_{2.5}$ standards, the Administrator has considered the combined protection afforded by both the annual and 24-hour standards, taking into account the forms discussed in Unit II.E. of this preamble.

With this approach in mind, the Administrator has considered the available health effects evidence and related air quality information presented in the Criteria Document and summarized in chapters IV--VII of the Staff Paper, which provides the basis for decisions on standard levels that would reduce risk sufficiently to protect public health with an adequate margin of safety, recognizing that such standards will not be risk-free. In so doing, the Administrator has considered both the strengths and the limitations of the available evidence and information, as well as alternative interpretations of the scientific evidence advanced by various CASAC panel members (Wolff, 1996b; Lippmann et al., 1996) and public commenters, arising primarily from the inherent uncertainties and limitations in the health effects studies.

Beyond those factors, but clearly related to them, a range of views have been expressed by CASAC panel members and the public as to the appropriate policy response to the available health effects evidence and related air quality information. Toward one end of the spectrum, the view has been expressed that only a very limited policy response is appropriate in light of the many key uncertainties and unanswered questions that, taken together, call into question the fundamental issue of causality in the reported associations between ambient levels of $PM_{2.5}$ and mortality and other serious health effects. Toward the other end, the view has been expressed that the consistency and coherence of the epidemiological evidence should be interpreted as demonstrating causality in the relationships between $PM_{2.5}$ and health endpoints that are clearly adverse, and that uncertainties in the underlying health effects information should be treated, regardless of their nature, as warranting a maximally precautionary policy response. A third view would suggest an alternative policy response, taking into account not only the consistency and coherence of the health effects evidence, but also the recognition of key uncertainties and unanswered questions that increasingly call into question the likelihood of PM-related effects as $PM_{2.5}$ concentrations decrease below the mean values in areas where effects have been observed and/or as such concentrations approach background levels.

Reflecting these divergent views, both of the science itself and of how the science should be used in making policy decisions on proposed standards, the Administrator considered three alternative approaches to selecting appropriate standard levels, as described in the proposal, ultimately deciding to propose standards based on a balanced view of the strengths and uncertainties of the scientific information that reflects the intermediate approach.

Judging by the public comments received, EPA accurately reflected the bases for divergent views. A substantial body of public comments supported revising the PM standards by adding $PM_{2.5}$ standards with levels at least as stringent as those proposed by the Administrator. In general, however, comments on levels for $PM_{2.5}$ standards revealed a strong dichotomy between those who recommended even stronger standards than proposed, and those who counseled against revising the standards at all. As noted above in this unit, many in this latter group made contingent recommendations with respect to the levels and other aspects of $PM_{2.5}$ standards, if the Administrator concluded that any revisions were appropriate.

This latter group of ''contingent'' commenters recommended levels well above those proposed by the Administrator. These commenters placed great weight on factors outlined in Units II.B. and II.C. of this preamble that led them to oppose any revisions to the PM standards, including the uncertainties and limitations in the available health effects studies considered individually, such as the possible existence of effects thresholds and unanswered questions regarding the causal agent(s) responsible for the reported health effects. Further, they emphasized the limited amount of research currently available that has measured $PM_{2.5}$ directly. A substantial group recommended that $PM_{2.5}$ standards be selected so as to be equivalent or close in stringency to the current PM_{10} standards, and cited the opinions of some CASAC PM panel members as support. Some of these commenters provided supplemental analyses of air quality data, arguing that they demonstrate that ''equivalent'' standards would be at $PM_{2.5}$ levels as

[36] The 40 CFR part 58 monitoring rule proposed to limit sites that would be eligible for comparisons to the 24-hour standard to population-oriented monitoring sites.

high as approximately 95 μg/m^3 24-hour average and 27 μg/m^3 annual average.

Having evaluated these comments, the Administrator rejects both their underlying rationale and the specific recommendations for $PM_{2.5}$ standard levels that result in similar or only marginally more protection than that afforded by the current PM_{10} standards. Aside from technical problems in the commenters' supporting analyses on the issue of defining ''equivalent'' standards,[37] the Administrator finds this approach inconsistent with her conclusions regarding the adequacy of the current standards and the need to provide additional protection as articulated in Unit II.B. of this preamble. The Administrator believes that, despite well recognized uncertainties, the consistency and coherence of the epidemiological evidence and the seriousness of the health effects require a more protective response than provided by ''equivalence'' or a marginal strengthening of the standards. Moreover, EPA believes that the standard levels should be based on the most recent assessment of the scientific criteria for PM, not on applying uncertain ratios to standard decisions based on much more limited evidence in 1987. The Administrator also rejects the premise of some[38] who suggest that adopting a standard that prompts little or no additional control would cause no delay in risk reduction as compared to conducting monitoring and research now and setting a more stringent standard after the next review. These comments do not consider the realities of implementing air quality standards, which ensure that such an approach would add several years to the risk reduction process. Thus, aside from her obligations under the statute,[39] the Administrator believes that the most prudent and appropriate course is to establish appropriately protective standards now that put into motion monitoring and strategy development programs, while at the same time pursuing an expanded research program to improve implementation and to inform the next periodic review of the criteria and standards.

In sharp contrast to the commenters discussed immediately above, a number of other commenters strongly supported standard levels more stringent than those proposed by EPA. These commenters supported EPA's conclusions regarding the epidemiological studies, but would place much less weight on uncertainties related to the concentration-response relationships for $PM_{2.5}$ as a surrogate for PM and the relative importance of various PM components. Based on their evaluation of the information, and citing the support of some CASAC panel members, these commenters variously recommended 24-hour $PM_{2.5}$ standards as low as 18 to 20 μg/m^3 and annual standards of 10 to 12 μg/m^3.[40]

EPA notes that setting such standards would result in commensurate reductions in health risks only if, in fact, there is a continuum of health risks down to the lower end of the ranges of air quality observed in the key epidemiological studies, and only if the reported associations are, in fact, causally related to $PM_{2.5}$ at the lowest concentrations measured. Setting standards at low levels where the possibility of effects thresholds is greater, and where there is greater potential that other elements in the air pollution mix (or some subset of particles within the fine fraction) become more responsible for (or modify) the effects being causally attributed to $PM_{2.5}$, might result in regulatory programs that go beyond those that are needed to effectively reduce risks to public health. While placing substantial weight on the results of the key health studies in the higher range of concentrations observed, EPA is persuaded that the inherent scientific uncertainties are too great to support standards based on the lowest concentrations measured in such studies, which approach the maximum range of $PM_{2.5}$ values estimated for short-term background conditions.

Having considered the comments reflecting the two contrasting views summarized above in this unit, the Administrator concludes that the approach she set forth in the proposal is the most appropriate for selecting levels for annual and 24-hour $PM_{2.5}$ standards. This approach focuses primarily on standard levels designed to limit annual $PM_{2.5}$ concentrations to somewhat below those where the body of epidemiological evidence is most consistent and coherent, in recognition of both the strengths and the limitations of the full range of scientific and technical information on the health effects of PM, as well as associated uncertainties, as interpreted by the Criteria Document, Staff Paper, and CASAC. The Administrator believes that this approach appropriately reflects the weight of the evidence as a whole.

In identifying $PM_{2.5}$ standard levels consistent with this overall approach, the Administrator has placed greatest weight on those epidemiological studies reporting associations between health effects and direct measures of fine particles, most notably those recent studies conducted in North America (summarized in Tables V-12 and V-13 of the Staff Paper).[41] Key considerations and study results upon which this approach is based are presented as follows.

As previously discussed, the Administrator has concluded that it is appropriate to select the level of the annual standard so as to protect against the range of effects associated with both short- and long-term exposures to PM,

[37] Nationwide $PM_{2.5}$ estimates have been derived from the current PM air quality data base, but reflect a significant degree of uncertainty due to the highly variable relationship between $PM_{2.5}$ and PM_{10} air quality values across locations and seasons (Fitz-Simons et al., 1996). The American Iron and Steel Institute (AISI) submitted a useful data base (Cooper Associates, 1997) on $PM_{2.5}/PM_{10}$ relationships that examines both these predictions and the issue of equivalence. An EPA examination of this material, which found some problems with the analysis and with commenters' conclusions that appear inconsistent with the Cooper report, is included in the Response to Comments.

[38] Some commenters suggest that CASAC and EPA support for $PM_{2.5}$ standards is based on the need to stimulate additional monitoring and research. While the Administrator agrees that the additional monitoring and research that would accompany establishment of equivalent or marginally tighter $PM_{2.5}$ standards are very important goals, they do not form an adequate rationale for establishing air quality standards.

[39] As stated previously, section 109(d) of the Act requires that, after reviewing the existing criteria and standards for PM, the Administrator make such revisions in the standards and promulgate such new standards as are appropriate under section 109(b) of the Act.

[40] This range of levels for a 24-hour $PM_{2.5}$ standard is close to the lower bound levels recommended by four CASAC panel members (20 μg/m^3); no member supported an annual $PM_{2.5}$ standard as low as 10 to 12 μg/m^3.

[41] Some confusion is apparent in comments regarding the basis on which the Administrator selected levels for the proposed $PM_{2.5}$ standards, with some commenters suggesting two or at most three studies were used, and others suggesting that EPA relied extensively on uncertain conversion factors to estimate levels for the standards. These comments are in error. To clarify, as stated in the proposal, the Administrator is basing her decision to revise the standards on the full range of PM health effects studies summarized in the Criteria Document and Staff Paper, but in selecting specific levels for $PM_{2.5}$ standards, is relying chiefly on U.S. and Canadian studies, listed in Tables V-12 and V-13 of the Staff Paper, that measured fine PM levels. To ease identification and use of these key studies, the short-term exposure studies and key PM air quality statistics are cited in Koman (1996) and all long-term exposure studies are cited in this preamble. The referenced memorandum (Koman, 1996) has been updated (Koman, 1997) to clarify key aspects of the studies cited and relevant air quality statistics. In accordance with EPA and CASAC views on the relative strength of these studies, greater weight is placed on short-term exposure studies than on long-term exposure studies. Where studies found statistically significant associations with $PM_{2.5}$ components (e.g., sulfates and/or acids, in Thurston et al., 1994; Dockery et al., 1996), the corresponding $PM_{2.5}$ or $PM_{2.1}$ values from the study are cited. No conversions were made from the original measurements used in these studies.

with the 24-hour standard level selected to provide supplemental protection against peak concentrations that might occur over limited areas and/or for limited time periods. In selecting the level for the annual standard, therefore, the Administrator has considered both short- and long-term exposure studies.

In accordance with EPA staff and CASAC views on the relative strengths of the epidemiological studies, the Administrator has placed greater emphasis on the short-term exposure studies in selecting the level of the annual standard. The approach she took to this issue consisted of determining a provisional level based on the short-term exposure studies, and then determining whether the long-term exposure studies are consistent with that level or, instead, suggest the need for a lower level. The effects estimates from the short-term exposure studies (in Table V-12 of the Staff Paper) are based on analyses of daily $PM_{2.5}$ concentrations that occurred over the course of the study period. While effects may occur over the full range of concentrations observed in the studies, consistent with the discussion of this issue in Unit II.D. of this preamble, the strongest evidence for short-term $PM_{2.5}$ effects occurs at concentrations near the long-term (e.g., annual) average. More specifically, the strength of the evidence of effects increases for concentrations that are at or above the long-term (e.g., annual) mean levels reported for these studies.[42] Given the serious nature of the potential effects, the Administrator believes it is both prudent and appropriate to select a level for an annual standard at or below such concentrations. An examination of the long-term means from the combined six city analyses of daily mortality (Schwartz et al., 1996a) and morbidity (Schwartz et al., 1994), together with those from studies in individual cities for which statistically significant PM-effects associations are reported (from Table V-12 in the Staff Paper), finds mean concentrations ranging from about 16 to about 21 $\mu g/m^3$ (Koman, 1996; 1997). In addition, the mean concentrations in cities where short-term exposure associations are characterized in the Criteria Document as nearly statistically significant (U.S. EPA, 1996a, p. 13-40) range from about 11 $\mu g/m^3$ to 30 $\mu g/m^3$. Taken together, and placing greatest weight on those studies that were clearly statistically significant, this evidence suggests that an annual standard level of 15 $\mu g/m^3$ is appropriate to reduce the risk of effects from short-term exposure to fine particles.

Before reaching a final conclusion, the Administrator also examined this level in light of the effects reported in epidemiological studies of long-term exposures to fine particles (Table V-13 in the Staff Paper), which may reflect the accumulation of daily effects over time as well as potential effects uniquely associated with long-term exposures. Even though subject to additional uncertainties, the long-term exposure studies provide important insights with respect to the overall protection afforded by an annual standard. These studies were examined for general consistency and support for the levels derived from the short-term exposure studies, and to determine whether they provide evidence that a more stringent level is needed.

The most direct comparison with the daily fine particle mortality studies is provided by two long-term prospective cohort studies (Dockery et al., 1993; Pope et al., 1995). The annual mean $PM_{2.5}$ concentration for the multiple cities included in these studies (6 and 50 cities, respectively) was 18 $\mu g/m^3$ (Dockery et al., 1993), and about 21-22 $\mu g/m^3$ for the larger Pope et al. (1995) study.[43] The Staff Paper assessment of the concentration-response results from Dockery et al. (1993) concluded that the evidence for increased risk was more apparent at annual concentrations at or above 15 $\mu g/m^3$ (Table E-3; U.S. EPA; 1996b).[44] EPA notes that the estimated mean values for most of the cities in Pope et al. (1995) are above 15 $\mu g/m^3$. As noted in the Staff Paper and the Criteria Document, the estimated magnitude of effects in both long-term exposure mortality studies may be related to higher historical concentrations than the affected communities experienced during the time period of the studies; this consideration suggests that a level of 15 $\mu g/m^3$ would incorporate a margin of safety. An examination of morbidity effects and long-term exposures is provided by the recent ''24 city'' studies, which found that reduced lung function and increased respiratory symptoms in children followed the gradient in annual mean concentrations of fine particles and/or acid-sulfate components of fine particles (Raizenne et al., 1996; Dockery et al., 1996). The results indicate a greater likelihood of effects at annual mean $PM_{2.1}$ levels above about 15 $\mu g/m^3$ (U.S. EPA, 1996b; Figure V-7). In the judgment of the Administrator, these studies are consistent with a standard level of 15 $\mu g/m^3$. While they provide some suggestion of risks extending to lower concentrations, they do not provide a sufficient basis for establishing a lower annual standard level.

Taking the epidemiological studies of both short- and long-term exposures together, the Administrator believes the concordance of evidence for PM effects and associated levels provides clear support for an annual $PM_{2.5}$ standard level of 15 $\mu g/m^3$. This level is below the range of annual data most strongly associated with both short- and long-term exposure effects, and because even small changes in annual means in this concentration range can make significant differences in overall risk reduction and total population exposures, the Administrator believes it will provide an adequate margin of safety against the effects observed in these epidemiological studies. Moreover, the means in areas where $PM_{2.5}$ concentrations were statistically significantly associated with daily mortality (about 16 to 21 $\mu g/m^3$) reflect a 7 to 9-year average; thus, the use of a 3-year mean will provide additional protection. Although the possibility of effects at lower annual concentrations cannot be excluded, the evidence for that possibility is highly uncertain and, as previously discussed, the likelihood of significant health risk, if any, becomes smaller as concentrations approach the lower end of the range of air quality observed in the key epidemiological studies and/or background levels.

The final annual standard will provide substantial protection against short-term as well as long-term exposures to particles. Nevertheless, for the reasons specified above, a spatially averaged annual standard cannot be expected to offer an adequate margin of safety against the effects of all potential short-term exposures in areas with strong local or seasonal sources. The

[42] As discussed in the proposal and Appendix E of the Staff Paper (U.S. EPA, 1996b, p. E-4), there is generally greatest statistical confidence in observed associations for levels at and above the mean concentration.

[43] Based on a public comment, EPA found that the mean of 18 $\mu g/m^3$ in Pope et al. (1995) reported in the Criteria Document and elsewhere was actually the mean of median values. Based on typical air quality relationships, the conventional arithmetic mean would be approximately 21 to 22 $\mu g/m^3$ (Freas, 1997). The lowest median concentration measured in this study (9 $\mu g/m^3$), which was relied upon by some commenters as a basis for annual standards of 10 $\mu g/m^3$, is about 11 to 12 $\mu g/m^3$ as an arithmetic mean.

[44] Based on public comments and a further evaluation of the underlying study, EPA concludes that the comparable assessment of the concentration-response function summarized in Table E-3 for Pope et al. (1995) is not appropriate, because it was based on a supplemental ''ecologic'' comparison for these cities and not on the far more reliable prospective-cohort analysis that was the main focus of the paper.

broad-based community studies considered in this review generally could not evaluate such peak exposure conditions directly. Given the public health purposes of the 24-hour standard, the Administrator believes it should be set at a level that generally supplements the control afforded by an annual standard and proposed an approach based on providing a reasonable degree of protection against the peak levels observed or expected in communities where health effects have been associated with daily levels of fine particles.

For the reasons specified in the previous unit, the Administrator has decided to use a 98th percentile concentration-based form of the standard. As noted in the proposal, the 98th percentile 24-hour $PM_{2.5}$ concentrations in cities with statistically significant or nearly significant short-term fine particle exposure-effects associations ranged from 34 μg/m³ to as high as 90 μg/m³ (Koman, 1996, 1997). Based on an examination of these results, EPA originally proposed a level for the 24-hour standard of 50 μg/m³, and solicited comments on higher and lower alternative levels.

In considering comments on alternative levels for the purpose of making a final decision on the 24-hour standard, the Administrator recognizes the significant uncertainties in identifying the extent of the incremental risk associated with single peak exposures to $PM_{2.5}$ in areas where the annual standard is met. Clearly, the risks associated with the 98th percentile air quality data used in the selecting the proposed level are from the same study cities that experienced long-term levels at varying amounts above that selected for the annual standard. It is unclear what risks might have been associated with such peak levels had the long-term averages in these areas been below that selected for the annual standard. Regardless of this uncertainty, it is clear that reducing the annual concentrations in such areas to that of the annual standard would reduce the risk associated with peak days, whatever the magnitude, as well as that associated with the far more numerous days with concentrations near the annual average. Given these uncertainties and the significant degree of protection afforded by the annual standard, the Administrator is persuaded that it is appropriate to adopt a different approach for selecting the levels of the 24-hour standard than the one proposed.

In making a final decision on an appropriate level for the 24-hour standard, the Administrator considered several key factors: the significant protection afforded against short-term exposures by the annual $PM_{2.5}$ standard; the role of the 24-hour standard in providing supplemental protection against peak exposures not addressed by the annual standard; the air quality and effects information in the studies cited above; the uncertainties in the risks associated with infrequent and isolated peak exposures in areas that meet the annual standard; the range of levels recommended by EPA staff and CASAC panel members; and the extensive public comment on the alternative levels proposed, which ranged between 20 and 65 μg/m³. Because of the approach of establishing the annual standard as the controlling standard, and, in particular, the decision to set the level at the lower end of the annual range, there is no need to consider levels in the lower portion of the 24-hour range below the level proposed. Therefore, the Administrator focused on evaluating the margin of safety associated with levels between 50 and 65 μg/m³.

As has been discussed in previous units, the extent of total risk over the course of a year associated solely with a limited number of peak exposures is uncertain, but it is considerably smaller than that associated with the entire air quality distribution. Further, the risk associated with infrequent peak 24-hour exposures in otherwise clean areas is not well enough understood at this time to provide a basis for selecting the more restrictive levels in the range of 50 to 65 μg/m³. On the other hand, it is clear that any standard level within this range would provide some margin of safety. Taking into account the factors outlined above, the Administrator has concluded that a 24-hour standard at the level of 65 μg/m³ would provide an effective limit in the role as a supplement to the annual standard. This level is at the upper end of the range recommended by staff and most CASAC panel members, and below the levels suggested by some CASAC panel members and by a number of public commenters. Although this level is not risk free, the Administrator believes that it would provide an appropriate degree of additional protection over that provided by the annual $PM_{2.5}$ standard. Accordingly, after weighing these factors in light of the scientific uncertainties, the Administrator believes that a 98th percentile 24-hour $PM_{2.5}$ standard of 65 μg/m³ would provide an adequate margin of safety against infrequent or isolated peak concentrations that could occur in areas that attain the annual standard of 15 μg/m³.

In the Administrator's judgment, the factors discussed above provide ample reason to believe that both annual and 24-hour $PM_{2.5}$ standards are appropriate to protect public health from adverse health effects associated with short- and long-term exposures to ambient fine particles. Further, she believes these factors provide a clear basis for judging that an annual $PM_{2.5}$ standard set at 15 μg/m³, in combination with a 24-hour standard set at 65 μg/m³, will protect public health with an adequate margin of safety.

G. Conclusions Regarding the Current PM_{10} Standards

1. *Averaging time and form.* In conjunction with $PM_{2.5}$ standards, the new function of PM_{10} standard(s) is to protect against potential effects associated with coarse fraction particles in the size range of 2.5 to 10 μm. Coarse fraction particles are plausibly associated with certain effects from both long- and short-term exposures (EPA 1996a,b). Based on qualitative considerations, deposition of coarse fraction particles in the respiratory system could be expected to aggravate effects in individuals with asthma. The Criteria Document and Staff Paper found support for this expectation in limited epidemiological evidence on the effects of coarse fraction particles, suggesting that aggravation of asthma and respiratory infections and symptoms may be associated with daily or episodic increases in PM_{10} that are dominated by coarse fraction particles. The potential build-up of insoluble coarse fraction particles in the lung after long-term exposures to high levels should also be considered.

Based on assessments of the available information in the Criteria Document and Staff Paper, both the staff and CASAC recommended retention of an annual PM_{10} standard. The staff, with CASAC concurrence, recommended retention of the current annual arithmetic mean form of the standard, which is the same form being adopted for the annual $PM_{2.5}$ standard. As noted in the staff assessment, the current annual PM_{10} standard offers substantial protection against the effects of both long- and short-term exposure to coarse fraction particles. Public comment was nearly unanimous in recommending retention of this standard. The Administrator therefore has decided to continue a long-term PM_{10} standard as an annual arithmetic mean, averaged over 3 years.

The staff and CASAC also recommended that consideration be

given to retention of a 24-hour standard to provide additional protection against potential effects of short-term exposures to coarse fraction particles. The staff, with CASAC concurrence, also recommended that if a 24-hour standard is retained, the form of the standard should be revised to provide a more robust target for coarse fraction particle controls. The Administrator originally proposed a 98th percentile form for the 24-hour PM_{10} standard based primarily on the reasons outlined above in this unit regarding the proposed form of the 24-hour $PM_{2.5}$ standard.

The EPA received few comments supporting elimination of the 24-hour PM_{10} standard. The main exceptions were some industries, most notably the mining industry, which as noted above in this unit, argued that the available data provide little evidence for coarse particle effects at current ambient levels. These groups, who generally opposed $PM_{2.5}$ standards, also argued that the daily PM_{10} standard could be eliminated if $PM_{2.5}$ standards were set. Based on the potential aggravation of respiratory symptoms from short-term exposure to coarse fraction particles discussed in the Criteria Document and by numerous commenters, as well as the recommendations of a majority of CASAC panelists who also supported $PM_{2.5}$ standards, the Administrator concludes it is appropriate to retain a 24-hour PM_{10} standard.

In general, comments received on the form of the 24-hour PM_{10} standard paralleled those on the form of the $PM_{2.5}$ standard. Substantial concerns were expressed by environmental groups, some States, and others that the 98th percentile would not provide an adequate limit on the number and magnitude of 24-hour peak PM_{10} excursions. While a number of these commenters suggested keeping the current 1-expected-exceedance form, EPA believes that a concentration- based percentile form offers significant advantages, as outlined above in this unit, for both PM indicators. Some air pollution control officials, who were concerned about the extent to which the 24-hour PM_{10} standard would be relaxed under the proposed form, suggested consideration of a 99th percentile form with increased monitoring as an appropriately protective form. Other commenters, particularly some industry groups and some States, strongly supported concentration-based percentile forms, with some recommending consideration of the 95th percentile form.

The proposal noted that a percentile value selected closer to the ''tail'' of the air quality distribution (e.g., a 99th or greater percentile) would not significantly increase stability as compared to the current form. However, an association of 8 State air pollution agencies commented that a 99th percentile form could provide increased stability if combined with a daily or 1-in-3-day sampling frequency and with greater data capture. In addition, EPA notes that this concentration-based form is inherently more stable than the current exceedance-based form.

Many of these and other commenters were concerned that the uncertainties in the available scientific information on the effects of coarse particles were a reason to be concerned that, assuming the current standard level was kept, a 98th percentile form would represent a significant relaxation in protection relative to the current standards. Unlike the situation for the new $PM_{2.5}$ standards, in the case of the PM_{10} standards, the 24-hour standard has generally been the ''controlling'' standard, making changes to the form of the 24-hour standard potentially more significant to the overall national level of protection afforded. Given the uncertainties in the available scientific evidence with respect to the potential health effects of short-term exposures to coarse fraction particles, the Administrator is persuaded that the somewhat more cautious approach with respect to revising the 24-hour PM_{10} standard recommended by many commenters is appropriate. The only approaches available for increasing the extent of protection for this standard as compared to that of the proposed standard involve modifying the form or reducing the level. For reasons discussed in the following section, the Administrator believes it is not appropriate to revise the level of the standard. In order to provide adequate protection against the potential risk associated with multiple short-term peak exposures to coarse fraction particles, the Administator accepts commenters' recommendations to decrease the frequency of peak values, while still providing for a more stable control target than afforded by the current 1-expected-exceedance form. Therefore, the Administrator concludes that the 99th percentile concentration-based form, averaged over 3 years, and combined with more frequent sampling, would be an appropriate form for a 24-hour PM_{10} standard.

2. *Levels for the annual and 24-hour PM_{10} standards*—a. *Annual PM_{10} standard.* As a result of the more limited information for coarse fraction particles, the Administrator's approach for selecting a level of the standard is directly related to the approach taken in the last review of the PM NAAQS. In that review, evidence from limited quantitative studies was used in conjunction with support from the qualitative literature in selecting the level of the current annual PM_{10} standard. In the current review, the staff assessment of the major quantitative basis for the level of that standard (Ware et al., 1986), together with a more recent related study (Dockery et al., 1989), recommended the same range of levels of concern (40 to 50 $\mu g/m^3$) as in the 1986 staff paper. The staff concludes that it is possible, but not certain, that coarse fraction particles, in combination with fine particles, may have influenced the observed effects at these levels. Based on particle deposition considerations, it is possible that cumulative deposition of coarse fraction particles could be of concern in children, who are more prone to be active outdoors than sensitive adult populations.

Qualitative evidence of other long-term coarse particle effects, most notably from long-term build-up of silica-containing materials, supports the need for a long-term standard, but does not provide evidence of effects below the range of 40 to 50 $\mu g/m^3$ (U.S. EPA, 1996a, p. 13-79). The staff concludes that the qualitative evidence with respect to biological aerosols also supports the need to limit coarse materials, but should not form the major basis for a national standard (U.S. EPA, 1996a, p. 13-79). In addition, staff notes that the nature and distribution of such materials, which vary from endemic fungi (e.g., valley fever) to pollens larger than 10 μm, are not appropriately addressed by traditional air pollution control programs.

Based on its review of the available information, CASAC found ''a consensus that retaining an annual PM_{10} NAAQS at the current level is reasonable at this time'' (Wolff, 1996b). With few exceptions, public comments supported levels at least as stringent as the current annual PM_{10} standard.[45] Taking into account these comments and the above considerations, as more fully detailed in the Staff Paper and the

[45] Some commenters, including some environmental groups and the State of California (Cal EPA, 1997), suggested that the large number of recent studies showing effects at PM_{10} levels below the current standards provides a basis for establishing stricter annual and 24-hour PM_{10} standards, in conjunction with $PM_{2.5}$ standards. As discussed in Units II.B. and C. of this preamble, while these studies could be used either to tighten the PM_{10} standards or to add standards that tighten control of the fine fraction of PM_{10}, the weight of evidence from all of the relevant information more readily supports the development of additional protection for the $PM_{2.5}$ fraction.

CASAC recommendations, the Administrator has decided to retain the current annual PM_{10} standard of 50 μg/m^3 to protect against the known and potential effects of long-term exposure to coarse fraction particles.

b. *24-hour PM_{10} standard.* As discussed above in this unit, EPA staff and CASAC also recommended that consideration be given to a 24-hour standard for coarse fraction particles as measured by PM_{10}. Unlike the case for the annual standard, however, the staff found that the original quantitative basis for the level of the current 24-hour PM_{10} standard (150 μg/m^3) is no longer appropriate. Instead, the staff found that the main quantitative basis for a short-term standard is provided by the two recent community studies of exposure to fugitive dust (Gordian et al., 1996; Hefflin et al., 1994). Because these studies reported multiple large exceedances of the current 24-hour standard, and because of limitations in the studies themselves, the staff concluded that they provide no basis to lower the level of the standard below 150 μg/m^3. Moreover, staff concluded that none of the qualitative literature regarding the potential effects of short-term exposure to coarse particles provides a basis for a lower standard level. Both EPA staff and CASAC recommended that if a 24-hour PM_{10} standard is retained, the level of the standard should be maintained at 150 μg/m^3, although with a revised form. Beyond the comments summarized above recommending elimination of the 24-hour standard, no commenters recommended a less stringent level, while some others, as summarized above in this unit, recommended more stringent levels. Most comments favored the current level.

Having considered these factors and the public comments, the Administrator judges that, retention of a 24-hour PM_{10} standard at the level of 150 μ/m^3 with a 99th percentile form is appropriate and will provide adequate protection against the known and potential effects of short-term coarse fraction particle exposures that have been identified to date in the scientific literature.

H. Final Decisions on Primary PM Standards

For the reasons discussed above in this unit, and taking into account the information and assessments presented in the Criteria Document and the Staff Paper, the advice and recommendations of CASAC, and public comments received on the proposal, the Administrator is revising the current PM NAAQS by adding new $PM_{2.5}$ standards and by revising the form of the current 24-hour PM_{10} standard. Specifically, the Administrator is making the following revisions:

(1) The suite of PM standards is revised to include an annual primary $PM_{2.5}$ standard and a 24-hour $PM_{2.5}$ standard.

(2) The annual $PM_{2.5}$ standard is met when the 3-year average of the annual arithmetic mean $PM_{2.5}$ concentrations, from single or multiple community-oriented monitors (in accordance with EPA's final rule on monitoring siting guidance, 40 CFR part 58, published in a separate document elsewhere in this issue of the **Federal Register**) is less than or equal to 15 μg/m^3, with fractional parts of 0.05 or greater rounding up.

(3) The 24-hour $PM_{2.5}$ standard is met when the 3-year average of the 98th percentile of 24-hour $PM_{2.5}$ concentrations at each population-oriented monitor within an area is less than or equal to 65 μg/m^3, with fractional parts of 0.5 or greater rounding up.

(4) The form of the current 24-hour PM_{10} standard is revised to be based on the 3-year average of the 99th percentile of 24-hour PM_{10} concentrations at each monitor within an area.

In addition, the Administrator is retaining the current annual PM_{10} standard at the level of 50 μg/m^3, which is met when the 3-year average of the annual arithmetic mean PM_{10} concentrations at each monitor within an area is less than or equal to 50 μg/m^3, with fractional parts of 0.5 or greater rounding up.

As discussed below in Units V. and VI. of this preamble, data handling conventions and completeness criteria for the revised standards are being established (40 CFR part 50, Appendix N). The reference method for monitoring PM as PM_{10} for the revised standards has been established (40 CFR part 50, Appendix M). A new reference method is being established for monitoring PM as $PM_{2.5}$ (40 CFR part 50, Appendix L). In a separate document published elsewhere in this issue of the **Federal Register**, EPA is providing opportunity for public comment on supplemental information relating to the new reference method for monitoring PM as $PM_{2.5}$ (40 CFR part 50, Appendix L).

As indicated previously, EPA plans to propose related revisions to the Pollutant Standards Index for PM (40 CFR 58.50) and the significant harm level program (40 CFR 51.66) at a later date.

III. Rationale for the Secondary Standards

The Criteria Document and Staff Paper examined the effects of PM on such aspects of public welfare as visibility, materials damage, and soiling. The following discussion of the rationale for revising the secondary standards for PM focuses on those considerations most influential in the Administrator's decision.

A. Need for Revision of the Current Secondary Standards

1. *Visibility impairment.* This unit of the document presents the Administrator's decision to address the welfare effects of PM on visibility by setting secondary standards identical to the suite of $PM_{2.5}$ primary standards, in conjunction with the establishment of a regional haze program under section 169A of the Act.[46] In the Administrator's judgment, this approach is the most effective way to address visibility impairment given the regional variations in concentrations of non-anthropogenic PM as well as other regional factors that affect visibility, such as humidity. By augmenting the protection provided by secondary standards set identical to the suite of $PM_{2.5}$ primary standards with a regional haze program, the Administrator believes that an appropriate degree of visibility protection can be achieved in the various regions of the country.

In coming to this decision, the Administrator took into account several factors, including: The pertinent scientific and technical information in the Criteria Document and Staff Paper, difficulties inherent in attempting to establish national secondary standards to address visibility impairment, the degree of visibility improvement expected through attainment of secondary standards equivalent to the suite of $PM_{2.5}$ primary standards, the effectiveness of addressing the welfare effects of PM on visibility through the combination of a regional haze program and secondary standards for $PM_{2.5}$ equivalent to the suite of primary standards, and comments received during the public comment period. The Administrator's consideration of each of these factors is discussed below in this unit.

The Administrator first concluded, based on information presented and referenced in the Criteria Document and

[46] Congress adopted section 169A of the Act because of concern that the NAAQS and Prevention of Significant Deterioration programs might not provide adequate visibility protection nationally, particularly for ''areas of great scenic importance.'' See H.R. Rep. No. 95–294,at 203–205 (1977).

Staff Paper, that particulate matter can and does produce adverse effects on visibility in various locations, depending on the PM concentrations involved and other factors discussed below. It has been demonstrated that impairment of visibility is an important effect of PM on public welfare, and that it is experienced throughout the United States, in multi-state regions, urban areas, and remote mandatory Class I Federal areas[47] alike. Visibility is an important welfare effect because it has direct significance to people's enjoyment of daily activities in all parts of the country. Individuals value good visibility for the well-being it provides them directly, both where they live and work, and in places where they enjoy recreational opportunities. Visibility is highly valued in significant natural areas, such as national parks and wilderness areas, because of the special emphasis given to protecting these lands now and for future generations. The Criteria Document cites many studies designed to quantify the benefits associated with improvements in visibility.

The Administrator considered information from the Staff Paper and Criteria Document regarding the effect of the composition of particulate matter on visibility. Visibility conditions are determined by the scattering and absorption of light by particles and gases, from both natural and anthropogenic sources. Visibility can be described in terms of visual range, light extinction, or deciview[48]. The classes of fine particles principally responsible for visibility impairment are sulfates, nitrates, organic matter, elemental carbon (soot), and soil dust. Fine particles are more efficient per unit mass at scattering light than coarse particles. The scattering efficiency of certain classes of fine particles, such as sulfates, nitrates, and some organics, increases as relative humidity rises because these particles can absorb water and grow to sizes comparable to the wavelength of visible light. In addition to limiting the distance that one can see, the scattering and absorption of light caused by air pollution can also degrade the color, clarity, and contrast of scenes.

The Administrator next considered what would be an appropriate level for a secondary standard to address adverse effects of particulate matter on visibility. The determination of a single national level is complicated by regional differences in visibility impairment due to several factors, including background and current levels of PM, composition of particulate matter, and average relative humidity.

The Criteria Document and Staff Paper describe estimated background levels of PM and natural light extinction. In the United States, estimated annual mean background levels of $PM_{2.5}$ are significantly lower in the West than in the East. Based on estimated background fine particle and light extinction levels summarized in Table VIII-2 of the Staff Paper, naturally occurring visual range in the East is approximately 105 to 195 kilometers, whereas in the West it is approximately 190 to 270 kilometers. This significant regional difference in estimated background conditions results from two main factors. First, in the western United States, visibility is more sensitive to an additional 1–2 $\mu g/m^3$ of $PM_{2.5}$ in the atmosphere than in the eastern United States. Secondly, light scattering is increased for certain particles (e.g., sulfates, nitrates, and some organics) due to higher average relative humidity in the East.

The combination of naturally occurring and manmade emissions also leads to significant differences in current visibility conditions between the eastern United States, 23–39 kilometers average visual range, and western United States, 55–150 kilometers average visual range. Table VIII-4 of the Staff Paper indicates that the current level of annual average light extinction in several western locations, such as the Colorado Plateau, is about equal to the level of background light extinction, i.e., the level generally regarded as representing the absence of anthropogenic emissions in North America, in the East. This regional difference is due to higher background particle concentrations in the East, a composition of fine particles in the East that, in association with higher eastern humidity levels, is more efficient at light scattering, and significantly lower concentrations of anthropogenic PM in remote western locations as compared with remote eastern sites.

Because of these regional differences, it is the Administrator's judgment that a national secondary standard intended to maintain or improve visibility conditions on the Colorado Plateau or other parts of the West would have to be set at or even below natural background levels in the East, which would effectively require elimination of all eastern anthropogenic emissions. Conversely, a national secondary standard that would achieve an appropriate degree of visibility improvement in the East would permit further degradation in the West. Due to this regional variability in visibility conditions created by differing background fine particle levels, fine particle composition, and humidity effects, the Administrator finds that addressing visibility solely through setting more stringent national secondary standards would not be an appropriate means to protect the public welfare from adverse impacts of PM on visibility in all parts of the country.[49] Aside from the problem of regional variability, the Administrator has also determined that the Agency currently lacks sufficient information to establish a level for a national secondary standard that would represent a threshold above which visibility conditions would always be adverse and below which visibility conditions would always be acceptable. Because visibility varies not only with PM concentration, but also with PM composition and humidity levels, attaining even a low concentration of fine particles might or might not provide adequate protection, depending on these factors.

The Administrator next assessed potential visibility improvements[50] that would result from attainment of the new primary standards for $PM_{2.5}$. The spatially averaged form of the annual standard is well suited to the protection of visibility, which involves effects of PM throughout an extended viewing distance across an urban area. Indeed, as

[47] There are 156 mandatory Class I Federal areas protected by the visibility provisions in sections 169A and 169B of the Act. These areas are defined in section 162 of the Act as those national parks exceeding 6,000 acres, wilderness areas and memorial parks exceeding 5,000 acres, and all international parks which were in existence on August 7, 1977.

[48] Visual range can be defined as the maximum distance at which one can identify a black object against the horizon sky. It is typically described in miles or kilometers. Light extinction is the sum of light scattering and absorption by particles and gases in the atmosphere. It is typically expressed in terms of inverse megameters (Mm^{-1}), with larger values representing poorer visibility. The deciview metric describes perceived visual changes in a linear fashion over its entire range, analogous to the decibel scale for sound. A deciview of 0 represents pristine conditions. Under many scenic conditions, a change of 1 deciview is considered perceptible by the average person.

[49] Congress adopted a visibility protection program in section 169A of the Act because it recognized the impracticability of revising the NAAQS to protect visibility in all areas of the country: ''It would be impracticable to require a major city such as New York or Los Angeles to meet the same visibility standards as the Grand Canyon and Yellowstone Park.'' See H.R. Rep. No. 95–294 at 205. (1977)

[50] Estimates of annual average visibility improvements assume that, on a percentage basis, the reduction for each fine particle component is equal to the % reduction in the mass of fine particles, and that the overall light extinction efficiency of the fine particle pollutant mix does not change. Further, for the estimates presented here, the reductions in fine mass at monitored locations are assumed to reflect the spatial average concentrations through the viewing distance. (Damberg and Polkowsky, 1996.)

the generally controlling standard focused on reducing urban and regional scale fine particle levels, most of the visibility protection provided by the $PM_{2.5}$ primary standards would be derived from the annual standard. In many cities having annual mean $PM_{2.5}$ concentrations exceeding 17 μg/m³, improvements in annual average visibility resulting from attainment of the new annual $PM_{2.5}$ primary standard are expected to be perceptible (i.e., to exceed 1 deciview). Based on annual mean $PM_{2.5}$ data reported in Table 12-2 of the Criteria Document and Table V-12 in the Staff Paper, many cities in the Northeast, Midwest, and Southeast, as well as Los Angeles, would be expected to see perceptible improvement in visibility if the annual $PM_{2.5}$ primary standard is attained.

In Washington, DC, for example, where the IMPROVE network[51] shows annual mean $PM_{2.5}$ concentrations at about 19 μg/m³ during 1992–1995, approximate annual average visibility would be expected to improve from 21 km visual range (29 deciview) to 27 km (27 deciview). Annual average visibility in Philadelphia, where annual $PM_{2.5}$ levels have been recently measured at 17 μg/m³, would be expected to change from about 24 to 27 km, an improvement of about 1 deciview. In Los Angeles, where recent data shows annual mean $PM_{2.5}$ concentrations at approximately 30 μg/m³, visibility would be expected to improve from about 19 to 34 km (30 to 24 deciview) if the new annual primary $PM_{2.5}$ standard is attained.

It is important to note that some urban areas, many in the eastern United States, would be expected to have annual mean $PM_{2.5}$ concentrations reduced below the primary standard level of 15 μg/m³ when implementation of regional control strategies for PM and other air quality programs, such as those addressing acid rain and mobile sources, are taken into account together. On the other hand, some urban areas with annual $PM_{2.5}$ levels at or below the 15 μg/m³ level would be expected to see little, if any, improvement in annual average visibility. This may be particularly true of certain western urban areas that are dominated by coarse rather than fine particles.

The Administrator also considered the potential effect on urban visibility if the 24-hour 98th percentile $PM_{2.5}$ standard of 65 m³ is attained. In areas with violations caused by localized hot spots, the 24-hour standard might have little effect other than on visible source emissions. In other areas, for example, with seasonally high woodsmoke, a more areawide improvement is possible. In such urban areas, attainment of the 24-hour standard would be expected to reduce, to some degree, the number and intensity of ''bad visibility'' days, i.e., the 20% of days having the greatest impairment over the course of a year. For example, maximum 24-hour $PM_{2.5}$ concentrations have been recorded in recent years at over 140 μg/m³ at several California locations. If the level and frequency of peak PM concentrations are reduced, improvements would be expected in those days where visibility is worst, even in urban areas having annual averages below the annual $PM_{2.5}$ primary standard.

Having concluded that attainment of the annual and 24-hour $PM_{2.5}$ primary standards would lead to visibility improvements in many eastern and some western urban areas, the Administrator also considered potential improvements to visibility on a regional scale. In the rural East, attainment of the $PM_{2.5}$ primary standards could result in regional visibility improvement, e.g., in certain mandatory Class I Federal areas such as Shenandoah and Great Smoky Mountains National Park, if regional control strategies are adopted and carried out in order to reduce the impact of long-range transport of fine particles such as sulfates. Fine particle emission reductions achieved by other air quality programs, such as those to reduce acid rain or mobile source emissions, are also expected to improve Eastern regional visibility conditions (U.S. EPA, 1993). In the West, strategies to attain the primary $PM_{2.5}$ standards are less likely to significantly improve visibility on a regional basis. However, areas downwind from large urban areas, such as Southern California, would likely see some improvement in annual average visibility.

Based on the foregoing, the Administrator concludes that attainment of $PM_{2.5}$ secondary standards set at the level of the primary standards for $PM_{2.5}$ would be expected to result in visibility improvements in the eastern United States at both urban and regional scales, but little or no change in the western United States except in and near certain urban areas. Additionally, the Administrator determined that attainment of secondary standards equivalent to the suite of $PM_{2.5}$ primary standards for particulate matter would address some but not all of the effects of particulate matter on visibility. The extent to which these effects would be addressed is expected to vary regionally.

The Administrator then considered the potential effectiveness of a regional haze program to address the remaining effects of particulate matter on visibility (i.e., those that would not be addressed through attainment of secondary standards identical to the suite of $PM_{2.5}$ primary standards). A program to address the widespread, regionally uniform type of haze caused by a multitude of sources is required by sections 169A and 169B of the Act. In 1977, Congress established as a national goal ''the prevention of any future, and the remedying of any existing, impairment of visibility in mandatory Class I Federal areas which impairment results from manmade air pollution'', section 169A(a)(1) of the Act. The EPA is required by section 169A(a)(4) of the Act to promulgate regulations to ensure that ''reasonable progress'' is achieved toward meeting the national goal. EPA originally deferred establishment of a program to address regional haze in 1980 due to the need for greater scientific and technical knowledge, but the current Criteria Document and Staff Paper cite information supporting the Administrator's conclusion that the scientific state of understanding and analytical tools are now adequate to develop such a program. Because regional emission reductions are needed to make visibility improvements in mandatory Class I Federal areas, the structure and requirements of sections 169A and 169B of the Act, provide for visibility protection programs that can be more responsive to the factors contributing to regional differences in visibility than can programs addressing a nationally applicable secondary NAAQS. The visibility goal is more protective than a secondary NAAQS since the goal addresses any man-made impairment rather than just impairment at levels determined to be adverse.

Thus, an important factor considered in this review is whether a regional haze program, in conjunction with secondary standards set identical to the suite of $PM_{2.5}$ primary standards, would provide appropriate protection for visibility in non-Class I areas. The Administrator continues to believe that the two programs and associated control strategies should provide such protection due to the regional approaches needed to manage emissions of pollutants that impair visibility in many of these areas. Regional strategies implemented to attain the NAAQS, meet other air program goals, and make reasonable progress toward the national visibility goal in mandatory Class I Federal areas are expected to improve

[51] IMPROVE (Interagency Monitoring of PROtected Visual Environments) is a visibility monitoring network managed cooperatively by EPA, Federal land management agencies, and State representatives. An analysis of IMPROVE data for 1992–1995 is found in Sisler et al. (1996).

visibility in many urban and non-Class I areas as well. The following recommendation from the 1993 report of the National Research Council, *Protecting Visibility in National Parks and Wilderness Areas,* addresses this point:

> Efforts to improve visibility in Class I areas also would benefit visibility outside these areas. Because most visibility impairment is regional in scale, the same haze that degrades visibility within or looking out from a national park also degrades visibility outside it. Class I areas cannot be regarded as potential islands of clean air in a polluted sea.

Before making a final decisions on the secondary standards, the Administrator also considered a number of public comments that addressed this aspect of the proposal. Some commenters suggested setting secondary standards for $PM_{2.5}$ more stringent than the proposed primary standards for the purpose of addressing visibility impairment and other environmental effects. For the reasons discussed above in this unit, however, the Administrator has concluded that this may not be an effective and would not be an appropriate means of protecting against visibility impairment in all parts of the country. Other commenters raised the possibility of establishing a nationally applicable secondary standard defined as a ''floor,'' or increment, above regionally specific background levels of $PM_{2.5}$ or associated visibility. Although this idea is of interest and may warrant further study, the Administrator determined that it was not appropriate to pursue such an approach at this time for two principal reasons. First, the Agency does not currently have adequate scientific information to establish a specific floor or increment level that would protect against adverse effects nationally, nor is it clear as a conceptual matter whether further information would support selection of a single, uniform increment as providing an appropriate degree of protection in all areas of the country. Second, there are serious, unresolved questions about whether such an approach is consistent with the statutory language and purposes of section 109 of the Act.

Other commenters argued that national secondary standards equivalent to the proposed $PM_{2.5}$ primary standards are not necessary or not supported by the Administrator's findings. As noted earlier, however, it is clear that coarse and fine particles can cause adverse effects on visibility and significant quantitative data exist to demonstrate that visibility impairment occurs at small concentrations of $PM_{2.5}$. Substantial efforts have been put forth to assess the effects of PM on visibility. For example, the Grand Canyon Visibility Transport Commission[52] spent several years and significant effort studying the effects of pollution on 16 mandatory Class I Federal areas on the Colorado plateau and has made recommendations to the Administrator for actions to improve visibility in these areas (GCVTC, 1996). All of the mandatory Class I Federal areas studied by the GCVTC with monitoring data have annual mean $PM_{2.5}$ concentrations below 5 $\mu g/m^3$ (Sisler, 1996) while also documenting anthropogenic visibility impairment. The Southern Appalachian Mountain Initiative[53] is currently assessing air pollution impacts on visibility, terrestrial resources, and aquatic resources in the southeastern U.S. in order to recommend measures to remedy existing and prevent future adverse effects on these air quality related values. The IMPROVE network shows that all of the mandatory Class I Federal areas in the SAMI region have annual mean $PM_{2.5}$ concentrations for 1992–95 between 11.0–13.5 $\mu g/m^3$ (Sisler, 1996). The inclusion in section 169A of the Act of a national visibility goal of no manmade impairment also places significant value on reducing PM concentrations and resulting visibility impairment to low levels.[54] The differences between the fine particle levels associated with visibility impairment in eastern and western mandatory Class I Federal areas provide further impetus to act under the provisions of sections 169A and 169B enabling the Administrator to establish a regionally-tailored visibility program to address impairment of visibility in mandatory Class I Federal areas. For these reasons, the Administrator has concluded that a national regional haze program allowing for regional approaches to addressing fine particle pollution, combined with a nationally applicable level of protection achieved through secondary $PM_{2.5}$ standards set equal to the suite of primary standards, would be more effective in addressing regional variations in the adverse effects of $PM_{2.5}$ on visibility than establishing national secondary standards for particulate matter that are lower than the suite of $PM_{2.5}$ primary standards. The Administrator emphasizes that in order to appropriately address the regional differences in adverse effects of particulate matter on visibility, it is essential to establish secondary standards for $PM_{2.5}$ equivalent to the primary standards and an effective new regional haze program. A regional haze program will be particularly important in those areas of the country that do not exceed any of the primary standards for $PM_{2.5}$, yet still experience significant visibility impairment due to particulate matter. The EPA will propose a regional haze regulation in the near future.

In addition to providing a more regionally tailored approach than establishing a more stringent national secondary standard, an effective regional haze program will also fulfill the Administrator's regulatory responsibility under sections 169A and 169B of the Act to address both reasonably attributable impairment and regional haze impairment in mandatory Class I Federal areas. Indeed, regional haze has been shown to be the principal cause of visibility impairment in mandatory Class I Federal areas today. Thus, the promulgation of a regional haze program in conjunction with secondary standards for $PM_{2.5}$ equivalent to the suite of primary standards will serve as an appropriate approach for addressing adverse effects of visibility that vary regionally, and it will also establish a comprehensive program for making reasonable progress toward the national visibility goal in mandatory Class I Federal areas by addressing visibility impairment in the form of both source-specific impacts and regional haze. Further, the regional haze rulemaking will fulfill the Administrator's responsibilities to address the visibility protection recommendations of the Grand Canyon Visibility Transport Commission, pursuant to section 169B(e) of the Act.

The Administrator recognizes that people living in certain urban areas may place a high value on unique scenic resources in or near these areas, and as a result might experience visibility problems attributable to sources that would not necessarily be addressed by the combined effects of a regional haze program and secondary standards identical to the suite of primary standards for $PM_{2.5}$. Commenters from

---

[52] EPA established the Grand Canyon Visibility Transport Commission (GCVTC) in 1991 under section 169B of the Act. Section 169B(d) requires visibility transport commissions to assess the ''adverse impacts on visibility from potential or projected growth in emissions'' and to recommend to EPA measures to remedy such adverse impacts. The Commission issued its final report in June 1996.

[53] The Southern Appalachian Mountain Initiative is a voluntary effort begun in 1993. Participants include eight southeastern States, Federal land managers, EPA, and representatives from industry and environmental groups. A final report has not been issued to date.

[54] Indeed, Congress recognized when it adopted section 169A that the ''visibility problem is caused primarily by emission into the atmosphere of sulfur dioxide, oxides of nitrogen and particulate matter, especially fine particulate matter, from inadequately controlled sources.'' H.R. Rep. No. 95–294 at 204 (1977).

certain western cities and States raised this issue. In the Administrator's judgment, State or local regulatory approaches, such as past action in Colorado to establish a local visibility standard for the City of Denver, would be more appropriate and effective in addressing these special situations because of the localized and unique characteristics of the problems involved. Visibility in an urban area located near a mandatory Class I Federal area can also be improved through State implementation of the current visibility regulations, by which emission limitations can be imposed on a source or group of sources found to be contributing to ''reasonably attributable'' impairment in the mandatory Class I Federal area. EPA also intends to pursue opportunities to obtain information on urban and non-Class I area visibility through examination of available fine particle monitoring data. Current or planned monitoring networks and initiatives, such as monitoring and chemical analysis of $PM_{2.5}$ in urban and background sites, efforts to better characterize real-time environmental conditions in major populations centers, and new automated airport visibility monitoring networks should provide data needed to evaluate trends in these areas. This information should help to better characterize the nature and spatial extent of urban and non-Class I visibility problems and thus serve to inform future decisions on NAAQS revisions or other appropriate measures.

Based on all of the considerations discussed, the Administrator has decided to establish secondary standards identical to the suite of $PM_{2.5}$ primary standards, in conjunction with a regional haze program under sections 169A and 169B of the Act, as the most appropriate and effective means of addressing the welfare effects associated with visibility impairment. Together, the two programs and associated control strategies should provide appropriate protection against the effects of PM on visibility and enable all regions of the country to make reasonable progress toward the national visibility goal.

2. *Materials damage and soiling effects.* Annual and 24-hour secondary standards for materials damage and soiling effects of PM were established in 1987 at levels equal in all respects to the primary standards. As discussed in the Criteria Document and Staff Paper, particles affect materials by promoting and accelerating the corrosion of metals, by degrading paints, and by deteriorating building materials such as concrete and limestone. Soiling is found to reduce the aesthetic quality of buildings and objects of historical or social interest. Past studies have found that residential properties in highly polluted areas typically have lower values than those in less polluted areas. Thus, at high enough concentrations, particles become a nuisance and result in increased cost and decreased enjoyment of the environment.

In the proposal, EPA proposed to establish secondary standards for PM_{10} and $PM_{2.5}$ identical to the suite of proposed primary standards. Several comments recommended setting secondary standards at levels more stringent than the proposed primary standards in order to address various welfare effects of PM, including soiling and materials damage, acid deposition, and visibility. Some commenters specifically suggested changing the form or level of the proposed 24-hour, 98th percentile PM standards to better protect against elevated PM episodes and associated soiling, materials damage, and visibility effects.

After reviewing the extent of relevant studies and other information provided since the 1987 review of the PM standards, the Administrator concurs with staff and CASAC conclusions that the available data do not provide a sufficient basis for establishing a separate secondary standard based on soiling or materials damage alone. In the Administrator's judgment, however, setting secondary standards identical to the suite of $PM_{2.5}$ and PM_{10} primary standards would provide increased protection against the effects of fine particles and retain an appropriate degree of control on coarse particles. Accordingly, the Administrator establishes the secondary standards for $PM_{2.5}$ identical to the suite of primary standards to protect against materials damage and soiling effects of PM.

B. Decision on the Secondary Standards

The Administrator establishes secondary standards identical to the suite of primary standards. In the Administrator's judgment, the establishment of these standards, in conjunction with implementation of a regional haze program, will provide appropriate protection against the welfare effects associated with particle pollution.

IV. Other Issues

Commenters have raised a number of legal and procedural issues that are discussed in this unit. These include:

(1) Whether EPA must give consideration to costs and similar factors in setting NAAQS.

(2) Whether EPA erred in its selection of a methodology for determining the level of a NAAQS that protects public health with an adequate margin of safety.

(3) Whether EPA committed a procedural error by not entering into the rulemaking docket underlying data from certain epidemiological studies.

(4) Whether the 1990 amendments to the Act preclude EPA from revising the PM NAAQS to establish a new $PM_{2.5}$ indicator.

Responses to other legal and procedural issues are included in the Response-to-Comments Document.

A. Consideration of Costs

For more than a quarter of a century, EPA has interpreted section 109 of the Act as precluding consideration of the economic costs or technical feasibility of implementing NAAQS in setting them. As indicated in the proposal, a number of judicial decisions have confirmed this interpretation. *Natural Resources Defense Council* v. *Administrator*, 902 F.2d 962, 972–973 (D.C. Cir. 1990)(PM NAAQS)(''PM_{10}''), vacated, in part, dismissed, 921 F.2d 326 (D.C. Cir.), certs. dismissed, 498 U.S. 1075, and cert. denied, 498 U.S. 1082 (1991); *Natural Resources Defense Council* v. *EPA*, 824 F.2d 1146, 1157–1159 (D.C. Cir. 1987)(en banc)(CAA section 112 standards for vinyl chloride)(''Vinyl Chloride''); *American Petroleum Institute* v. *Costle*, 665 F.2d 1176, 1185–1186 (D.C. Cir. 1981)(ozone NAAQS)(''Ozone''), cert. denied, 455 U.S. 1034 (1982); *Lead Industries Ass'n* v. *EPA*, 647 F.2d 1130, 1148–1151 (D.C. Cir.)(lead NAAQS)(Lead Industries), cert. denied, 449 U.S. 1042 (1980).

Some commenters have argued that costs and similar factors should, nonetheless, be considered, both in this rulemaking and in the rulemaking on proposed revisions to the NAAQS for ozone. Although most of the commenters' arguments are inconsistent with the judicial decisions cited in this unit, several commenters have argued that those decisions are not dispositive. For reasons discussed in this unit and in the Response-to-Comments Document, EPA disagrees with these comments and maintains its longstanding interpretation of the Act as precluding consideration of costs and similar factors in setting NAAQS.

1. *Background.* Given the nature of the points raised, a brief review of the issue seems useful before addressing the comments. The requirement that EPA establish national ambient air quality standards for certain pollutants, to be implemented by the States, was enacted in 1970 as part of a set of comprehensive amendments that established the basic framework for

Federal, State, and local air pollution control. When EPA promulgated the original NAAQS in 1971, its first Administrator, William D. Ruckelshaus, concluded that costs and similar factors could not be considered in that decision.[55] This conclusion was not challenged in litigation on the original NAAQS. It has been confirmed since then, however, by every judicial decision that has considered the issue.

As discussed in this unit, EPA's interpretation rests primarily on the language, structure, and legislative history of the statutory scheme adopted in 1970. It is also supported by the judicial decisions cited in this unit, as well as by legislative developments since 1970 that reaffirm Congress' original approach to the issue.

Without cataloguing all relevant aspects of the 1970 amendments and their legislative history, several basic points should be noted. Under section 109(b) of the Act, NAAQS are to be ''based on'' the air quality criteria issued under section 108 of the Act. Under section 108(a)(2) of the Act, the kind of information EPA is required to include in criteria documents is limited to information about health and welfare effects ''which may be expected from the presence of [a] pollutant in the ambient air * * * .'' There is no mention of the costs or difficulty of implementing the NAAQS, nor of ''effects'' that might result from implementing the NAAQS (as opposed to effects of pollution in the air).[56] By contrast, Congress explicitly provided for consideration of costs and similar factors in decisions under other sections of the Act.[57] Moreover, States were permitted to consider economic and technological feasibility in developing plans to implement the NAAQS to the extent such consideration did not interfere with meeting statutory deadlines for attainment of the standards.[58] Finally, the legislative history indicated that Congress had considered the issue and had deliberately chosen to mandate NAAQS that would protect health regardless of concerns about feasibility.[59]

The first judicial decision on the issue came in the Lead Industries case. An industry petitioner argued that EPA should have considered economic and technological feasibility in allowing a ''margin of safety'' in setting primary standards for lead. Based on a detailed review of the language, structure, and legislative history of the statutory scheme, the U.S. Court of Appeals for the District of Columbia Circuit concluded that:

> This argument is totally without merit. [The petitioner] is unable to point to anything in either the language of the Act or its legislative history that offers any support for its claim * * * . To the contrary, the statute and its legislative history make clear that economic considerations play no part in the promulgation of ambient air quality standards under section 109.

647 F.2d at 1148.

The Court cited a number of reasons for this conclusion. *Id.* at 1148–1150. Among other things, it noted the contrast between section 109(b) of the Act and other provisions in which Congress had explicitly provided for consideration of economic and technological feasibility, as well as the requirement that NAAQS be based on air quality criteria defined without reference to such factors. *Id.* at 1148–1149 and n.37. The Court also noted that, in developing plans to implement NAAQS, States may consider economic and technological feasibility only to the extent that this does not interfere with meeting the statutory deadlines for attainment of the standards; and that EPA may not consider such factors at all in deciding whether to approve State implementation plans. *Id.* at 1149 n.37 (citing *Union Electric Co.* v. *EPA*, 427 U.S. 246, 257–258, 266 (1976)).[60]

As to the legislative history of the 1970 amendments, the Court observed that:

> [T]he absence of any provision requiring consideration of these factors was no accident; it was the result of a deliberate decision by Congress to subordinate such concerns to the achievement of health goals.

Id. at 1149. Citing several leading Supreme Court decisions, as well as the Senate report quoted in this unit, the Court noted that Congress had intended a drastic change in approach toward the control of air pollution in the 1970 amendments and was well aware that sections 108–110 of the Act imposed requirements of a ''technology-forcing'' character. *Id.*[61]

The Court also noted that Congress had already acted, in further amendments adopted in 1977, to relieve some of the burdens imposed by the 1970 amendments. *Id.* at 1150 n.38. Observing that Congress had, however, declined to amend section 109(b) of the Act to provide for consideration of costs and similar factors as requested by industrial interests, *Id.* n.39, the Court concluded:

> A policy choice such as this is one which only Congress, not the courts and not EPA, can make. Indeed, the debates on the [1970 amendments] indicate that Congress was quite conscious of this fact * * * .
>
> * * * [I]f there is a problem with the economic or technological feasibility of the lead standards, [the petitioner], or any other party affected by the standards, must take its case to Congress, the only institution with the authority to remedy the problem.

Id. at 1150.

After the decision in Lead Industries, Supreme Court review was sought on the question whether costs and similar factors could be considered in setting NAAQS, among other issues. The Supreme Court declined to review the decision. *Lead Industries Ass'n* v. *EPA*, 449 U.S. 1042 (1980). The subsequent decisions in Ozone, Vinyl Chloride, and PM_{10}, cited in this unit, strongly reaffirmed the interpretation adopted in Lead Industries.[62] Supreme Court

---

[55] 36 FR 8186, April 30, 1971. EPA has maintained this interpretation consistently since then.

[56] That consideration of such factors was not intended in NAAQS decisions is also supported by section 109(a)(1) of the Act. For pollutants for which air quality criteria had been issued prior to the 1970 amendments, that provision required EPA to propose NAAQS within 30 days after enactment and to take final action 90 days later. The criteria issued previously did not include information on costs and similar factors, and it would have been difficult if not impossible for EPA to supplement them in time to include meaningful consideration of such factors in NAAQS proposed 30 days after enactment.

[57] See, e.g., sections 110(e)(1), 111(a)(1), 231(b) of the 1970 Act; see also, e.g., sections 113(d)(4)(C)(ii), 125(a)(3), 202(a)(3)(C), 317 of the 1977 Act.

[58] *Union Electric Co.* v. *EPA*, 427 U.S. 246, 257–58 (1976).

[59] The Senate report on the 1970 amendments stated: ''In the Committee discussions, considerable concern was expressed regarding the use of the concept of technical feasibility as the basis of ambient air standards. The Committee determined that (1) the health of people is more important than the question of whether the early achievement of ambient air quality standards protective of health is technically feasible; and, (2) the growth of pollution load in many areas, even with application of available technology, would still be deleterious to public health.''

''Therefore, the Committee determined that existing sources of pollutants either should meet the standard of the law or be closed down * * * .''

S. Rep. No. 91–1196, at 2–3 (1970).

[60] These limitations would, of course, make little sense if such factors could be considered in setting the NAAQS themselves.

[61] Such requirements ''are expressly designed to force regulated sources to develop pollution control devices that might at the time appear to be economically or technologically infeasible.''' *Id.* (quoting *Union Electric Co.* v. *EPA*, 427 U.S. at 257).

[62] In the PM_{10} case, for example, the Court considered an argument that EPA should have considered potential health consequences of unemployment that might result from revision of the primary NAAQS for PM:

> ''This claim is entirely without merit. In three previous cases, this court has emphatically stated that § 109 does not permit EPA to consider such costs in promulgating national ambient air quality standards * * * . It is only *health effects relating to pollutants in the air* that EPA may consider * * * . Consideration of costs associated with alleged health risks from unemployment would be flatly inconsistent with the statute, legislative history and case law on this point.''

902 F.2d at 973 (emphasis in original; citations omitted).

review of the Ozone and PM_{10} decisions was sought but denied. *American Petroleum Institute* v. *Gorsuch,* 455 U.S. 1034 (1984); *American Iron and Steel Institute* v. *EPA*, 498 U.S. 1082 (1991).

The Lead Industries opinion focused largely, though not exclusively, on the 1970 amendments and their legislative history. Perhaps as a result, it did not canvass all the factors that, in fact, supported its conclusions at the time. For example, when Congress enacted major amendments to the Act in 1977, it was clearly aware that some areas of the country had experienced difficulty in attempting to attain some of the NAAQS.[63] It was also aware that there might be no health-effects thresholds for the pollutants involved, and that significant uncertainties are inherent in setting health-based standards under the Act.[64] In response, Congress made significant changes in the provisions for implementation of the NAAQS, including changes intended to ease the burdens of attainment. It also amended sections 108 and 109 of the Act in several ways; for example, by requiring periodic review and, if appropriate, revision of air quality criteria and NAAQS and by establishing a special scientific advisory committee (CASAC) to advise EPA on such reviews. Notably, Congress recognized that implementation of NAAQS could cause ''adverse public health, welfare, social, economic, or energy effects'' and charged CASAC with advising EPA on such matters.[65] Yet it made no changes in section 109(b) or section 108(a)(2) of the Act; that is, in the substantive criteria for setting or revising NAAQS. In other words, Congress chose to address economic and other difficulties associated with attainment of the NAAQS by adjusting the scheme for their implementation, rather than by changing the instructions for setting them.[66]

Congress enacted major amendments to the Act again in 1990, well after the Lead Industries and Ozone decisions that interpreted section 109 of the Act as precluding consideration of costs in NAAQS decisions.[67] In doing so, Congress was clearly aware of intervening developments such as EPA's decision to revise the PM NAAQS in 1987—the result of an elaborate review in which the Administrator strongly underscored the scientific uncertainties involved[68]—and the Vinyl Chloride case drawing a sharp distinction between sections 109 and 112 of the Act with regard to consideration of costs and similar factors.[69] Indeed, the legislative history of the 1990 amendments reflects Congress' understanding that primary NAAQS were to be based on protection of health ''without regard to the economic or technical feasibility of attainment.''[70] Again, however, Congress chose to respond to severe, widespread, and persistent problems with attaining the NAAQS by adjusting the scheme for their implementation rather than by changing the basis for setting them. See, e.g., sections 181–192 of the Act.

2. *Public comments.* As noted previously, a number of commenters have argued that costs and similar factors should be considered in EPA's final decisions on revision of both the particulate and ozone NAAQS. Aside from arguments that are simply inconsistent with the judicial decisions cited in this unit, some of the commenters argue that those decisions are not dispositive for a variety of reasons. One commenter submitted a particularly comprehensive version of this argument; the following discussion focuses primarily on points raised by that commenter, among others.[71]

As a general matter, the commenter acknowledges that Congress intended to preclude consideration of economic costs and similar factors in setting NAAQS. The commenter argues, however, that this is so only when the scientific basis for NAAQS is ''clear and compelling'' or ''unambiguous.'' From that premise, the commenter advances three key assertions:

a. Where non-threshold pollutants are involved and the health evidence is ambiguous, section 109 of the Act must be interpreted to allow consideration of all relevant factors, including the practical consequences of EPA's decisions.

b. To the extent the judicial decisions cited in this unit are read as precluding this, they rest on a faulty analysis that pre-dates and cannot survive scrutiny under *Chevron, U.S.A.* v. *Natural Resources Defense Council,* 467 U.S. 837 (1984).[72]

c. Because EPA has discretion to consider costs and similar factors where the health evidence is ambiguous, it must do so in light of Executive Order 12866 (58 FR 51735, October 4, 1993), and two recent statutes, the Unfunded

---

[63] See, e.g., H.R. Rep. No. 95-294, at 207–217 (l977).

[64] See, e.g., *Id.* at 110–112; *Id.* at 43-51.

[65] Section 109(d)(2)(C)(iv) of the Act. Some commenters have argued that this provision requires EPA to consider such effects in setting NAAQS. From the language and structure of section 109(d) of the Act, however, it is clear that CASAC's responsibility to advise on these factors is separate from its responsibility to review and recommend revision of air quality criteria and NAAQS, and that the advice pertains to the implementation of NAAQS rather than to setting them. The legislative history confirms this view, indicating that the advice was intended for the benefit of the States and Congress. See H.R. Rep. No. 95-294, at 183 (1977).

[66] The 1977 amendments also required EPA to prepare economic impact assessments for specified actions but limited the requirement to non-health-based standards, excluding decisions under sections 109 and 112 of the Act. Section 317; H.R. Rep. No. 95-294, at 51–52 (1977). In this and other respects, Congress continued the approach it took in the l970 amendments, making careful choices as to when consideration of costs and similar factors would be required and giving paramount priority to protection of health. See 123 Cong. Rec. H8993 (daily ed. Aug. 4, 1977) (Clean Air Conference Report (1977); Statement of Intent; Clarification of Select Provisions), reprinted in 3 Senate Committee on Environment and Public Works, 95th Cong., A Legislative History of the Clean Air Act Amendments of 1977, at 319 (1978).

[67] In the interim, the National Commission on Air Quality had also submitted its report to Congress as required by a provision of the 1977 amendments. Among other things, the Commission recommended that the statutory approach of requiring NAAQS to be set at levels necessary to protect public health, without consideration of economic factors, be continued without change. National Commission on Air Quality, To Breathe Clean Air 55 (1981).

[68] As the Administrator indicated in EPA's proposal to revise the PM standards:

''[T]hat review has revealed a highly limited data base—particularly where quantitative studies are concerned—and a wide range of views among qualified professionals about the exact pollution levels at which health effects are likely to occur. The setting of an 'adequate margin of safety' below these levels calls for a further judgment—in an area for which the scientific data base is even more sparse and uncertain * * * .''

''* * * [L]ong and expert review of public health issues has to date revealed no scientific method of assessing exactly what level of standards public health requires. The scientific review indicates substantial uncertainties concerning the health risks associated with lower levels of particulate matter.'' (49 FR 10408, 10409, March 20, l984)

[69] Congress was clearly aware of the 1987 decision to revise the PM NAAQS, which among other things involved changing the indicator for particulate matter from ''total suspended particulate'' to PM_{10}, because it enacted special nonattainment provisions, as well as provisions for PSD increments, applicable to PM_{10}. Sections 188–190 of the Act; section 166(f) of the Act. It was clearly aware of the Vinyl Chloride decision because it amended section 112 of the Act in response to that decision, essentially creating a new scheme for setting emission standards for hazardous pollutants.

[70] H.R. Rep. No. 101–490, pt. 1, at 145 (1990). See also S. Rep. No. 101–228, at 5 (1989).

[71] Additional responses to points raised by this commenter and others are included, as appropriate, in the Response-to-Comments Document.

[72] Several other commenters argue that the cited decisions are not dispositive because they held only that EPA is not required to consider costs and similar factors in setting NAAQS. As discussed in this unit in connection with Chevron, however, the decisions clearly concluded that Congress intended to preclude consideration of such factors, and that EPA is not free to alter that congressional choice. Although these conclusions are technically dicta, nothing in the Court's opinions suggests that it would have interpreted section 109 of the Act differently had EPA claimed authority to consider costs and similar factors in NAAQS decisions. Indeed, the tone of the opinions argues to the contrary. See, e.g., PM_{10}, 902 F.2d at 973. Cf. *Ethyl Corp.* v. *EPA,* 51 F.3d 1053 (D.C. Cir. 1995).

Mandate Reform Act of 1995, 2 U.S.C. 1501–1571 (UMRA), and the Small Business Regulatory Enforcement Fairness Act of 1996, Pub. L. 104–121, 110 Stat. 857 (SBREFA), which in part amended the Regulatory Flexibility Act, 5 U.S.C. 601–808.

EPA believes all three assertions are clearly incorrect. Regarding the first point, it should be evident, both from previous NAAQS decisions and from the court opinions upholding them, that the scientific basis for NAAQS decisions has never pointed clearly and unambiguously to a single ''right answer.''[73] This is inherent in the statutory scheme for the establishment and revision of NAAQS, which in effect requires them to be based on the ''latest scientific knowledge'' on potential health and welfare effects of the pollutant in question. See sections 109(b) and 108(a)(2) of the Act. Although advances in science increase our understanding of such effects, they also raise new questions. For this reason, the key studies for any given decision on revision of a NAAQS are, almost by definition, ''at the very 'frontiers of scientific knowledge.'''[73] That is, studies that call into question the adequacy of a standard are always those that go beyond previous studies—by reporting new kinds of effects, for example, or effects at lower concentrations than those at which effects have been reported previously.

As with pioneering work in other fields, such studies may have a variety of strengths and limitations.[8][75] As a result, the validity and implications of such studies may be both uncertain and highly controversial. Given the precautionary nature of section 109 of the Act,[76] however, it is precisely these kinds of studies that the Administrator must grapple with when advances in science suggest that revision of a NAAQS is appropriate.

As a result, the EPA staff typically recommends for consideration, and the Administrator may propose for comment, a range of alternatives based on what the commenter would call ''ambiguous'' science. In this respect, the current reviews of the NAAQS for ozone and particulate matter are not unusual and do not differ, for example, from the review that led to adoption of the PM_{10} NAAQS in 1987.[77] Indeed, the NAAQS that were upheld in the Lead Industries, Ozone, and PM_{10} decisions were all based on highly controversial health evidence; the Lead Industries decision took note of congressional statements recognizing that there may be no thresholds for criteria pollutants; and the Ozone and PM_{10} decisions noted the Administrator's findings that clear thresholds could not be identified for ozone and particulate matter, respectively.[78] Thus, the present decisions on revision of the NAAQS for ozone and particulate matter cannot be distinguished from those past decisions in terms of the nature of the health evidence or pollutants involved.[78]

Regarding the second of the commenter's key assertions, EPA determines it is clear that the judicial decisions cited in this unit were correctly decided and continue to be good law under Chevron. In Chevron, the Supreme Court essentially reaffirmed the principle that courts must defer to reasonable agency interpretations of the statutes they administer where Congress has delegated authority to them to elucidate particular statutory provisions. Where the intent of Congress on an issue is clear, however, it must be given effect by the agency and the courts. See 467 U.S. at 842–45. Thus, the first question on review of an agency's interpretation under Chevron is ''whether Congress has directly spoken to the precise question at issue.'' If the court determines that it has not, the remaining question for the court is ''whether the agency's answer is based on a permissible construction of the statute.'' 467 U.S. at 842–843 (footnote omitted). In determining whether Congress ''had an intention on the precise question at issue,'' a court employs ''traditional tools of statutory construction.'' *Id.* at 843 n.9.[80]

In essence, the commenter's argument here is that the Lead Industries decision did not address whether Congress had ''spoken directly'' to the precise issue posed by the commenter; that is, whether section 109 of the Act must be interpreted differently for NAAQS decisions involving non-threshold pollutants and ''ambiguous'' health evidence. The Lead Industries opinion, which pre-dated Chevron, did not pose the question in those terms. Its focus, however, was clearly on what Congress intended to be the basis for NAAQS decisions, in a context the Court understood to involve considerable uncertainty and debate about the health evidence, as well as the possibility that there was no threshold for health effects of the pollutant.[81] In short, the health evidence was hardly ''unambiguous,'' yet the Court interpreted section 109 of this Act as precluding consideration of costs and similar factors even in allowing a margin of safety. Nothing in the Lead Industries decision or in the subsequent cases suggests in any way that section 109 of the Act should be interpreted differently based on the nature of the pollutants or health evidence involved, and the Court's findings on congressional intent admit of no exceptions:

> * * * [T]he statute and its legislative history make clear that economic considerations play no part in the promulgation of ambient air quality standards under Section 109.

647 F.2d at 1148.

Alternatively, the commenter argues that the Lead Industries case decided the issue incorrectly in light of the principles announced subsequently in Chevron. In this context, the commenter essentially argues that the Lead Industries decision rested on two factors that are no longer probative:

(1) That there was no indication that Congress meant to allow consideration of costs in NAAQS decisions, and

(2) That Congress specifically provided for such consideration in other sections of the Act but not in section 109.

---

[73] See, e.g., Lead Industries, 647 F.2d at 1146–1147, 1153–1156, 1160–1161, 1167 n.106. In enacting the 1970 amendments, Congress was aware that there were gaps in the scientific information available then as a basis for establishing the original NAAQS. See, e.g., S. Rep. No. 91-1196, at 9–11 (1970). If anything, Congress had an even greater understanding of the point when it enacted the 1977 amendments without changing the substantive criteria for setting NAAQS. See H.R. Rep. No. 95-294, at 43–51, 181–182 (1977).

[74] Lead Industries, 647 F.2d at 1147 (quoting *Ethyl Corp.* v. *EPA*, 541 F.2d 1, 24–27 (D.C. Cir.) (en banc), cert. denied, 426 U.S. 941 (1976)).

[75] They may have methodological flaws, for example, but nonetheless report effects that are of serious medical significance; or they may be of impeccable quality but involve effects of uncertain significance. Others may involve results that are striking but hard to explain in terms of previous knowledge, or results that seem plausible and important but are not yet replicated by other studies.

[76] See, e.g., Lead Industries, 647 F.2d at 1155–1156; H.R. Rep. No. 94-295, at 43–51 (1977).

[77] As previously discussed, the Administrator strongly emphasized the uncertainties involved in that review. As a result of the uncertainties, he proposed ''relatively broad'' ranges for comment, though he focused on lower levels within the ranges as providing greater margins of safety against the health risks involved. See 49 FR 10408, 10409, March 20, l984.

[78] See, e.g., Lead Industries, 647 F.2d at 1152–53 and n. 43, 1159–60; Ozone, 665 F.2d at 1185, 1187; PM_{10}, 902 F.2d at 969–71, 972.

[79] Indeed, the present decisions on the NAAQS for PM and ozone are based on some of the best scientific information the Agency has ever been able to rely on in NAAQS decision-making. In particular, the science underlying these decisions is much more extensive and of much better quality than the science underlying the existing NAAQS for PM and ozone.

[80] In practice, analysis of this question is sometimes referred to as a ''Chevron step one'' analysis.

[81] See, e.g., 647 F.2d at 1148–51, 1152–53 and n.43, 1160–61.

On the first point, the commenter argues that EPA is free under Chevron to consider costs and similar factors (by reinterpreting section 109 of the Act) unless there is evidence that Congress intended to restrict its discretion. As to the second point, the commenter argues that similar reasoning was rejected in Vinyl Chloride.

In Vinyl Chloride, however, an en banc decision that post-dated Chevron, the Court essentially underscored the point that such issues cannot be decided mechanically but must turn, instead, on more analytical attention to relevant indicia of congressional intent. See, e.g., 824 F.2d at 1157 n.4; *Id.* at 1157–1163. With reference to NAAQS decisions in particular, the Court concluded that there were concrete indications of congressional intent to preclude consideration of costs and similar factors; for example, the fact that section 108 of the Act ''enumerate[s] specific factors to consider and pointedly exclude[s] feasibility.'' 824 F.2d at 1159. In a later case, moreover, the same Court held that EPA could not consider certain factors, in decisions under section 211(f)(4) of the Act, for reasons exactly parallel to those that the commenter criticizes in Lead Industries. See *Ethyl Corp.* v. *EPA*, 51 F.3d 1053, 1057–1063 (D.C. Cir. 1995).

Beyond this, the commenter's characterization of the Lead Industries decision ignores or discounts much of the key evidence cited by the Court, including the language, structure, and legislative history of the statutory scheme established in 1970, for its conclusion that Congress intended to preclude consideration of costs and similar factors in NAAQS decisions.[82] As indicated in this unit, the Vinyl Chloride and PM_{10} cases, both of which post-dated Chevron, reached the same conclusion.

Moreover, this series of decisions went far beyond mere deference to an agency interpretation. As indicated in the Vinyl Chloride case, the Lead Industries court found ''clear evidence'' of Congressional intent, which was to limit the factors EPA may consider under section 109 of the Act. 824 F.2d 1159. Consistent with Chevron, these findings were based on traditional tools of statutory construction. See *Id.* at 1157–1159; Lead Industries, 647 F.2d at 1148–1151. In terms of the analytical framework later established by Chevron, these were Chevron step one findings, meaning that the statute spoke directly to the issue and that the courts, as well as the agency, must give effect to Congress' intent as so ascertained. See 467 U.S. at 842–843.[83] Thus, absent a more recent legislative enactment overriding that intent, EPA has no discretion to alter its longstanding interpretation that consideration of costs and similar factors is precluded in NAAQS decisions under section 109 of the Act.[84]

As to the commenter's third key assertion, Executive Order 12866, UMRA sections 202 and 205, and the Regulatory Flexibility Act (RFA), as amended by SBREFA, do not conflict with this interpretation or require a different result. Basically, the commenter argues that the Executive Order, UMRA, and the RFA (as amended by SBREFA) require agencies to use cost (or similar factors) as a decisional criterion in making regulatory decisions, and that this modifies the Clean Air Act's directive that EPA is precluded from considering costs when setting a NAAQS. The commenter's argument is flawed on a number of grounds. First, UMRA and the RFA (as amended by SBREFA) do not conflict with section 109 of the Act because they do not apply to this decision, as discussed in Unit VIII. of this preamble. Second, the Executive Order and both statutes are quite clear that they do not override the substantive provisions in an authorizing statute. Third, the commenter's premise that UMRA and the RFA (as amended by SBREFA) establish substantive decisional criteria that agencies are required to follow is wrong.

As a matter of law, the Executive Order cannot (and does not purport to) override the Clean Air Act. The Executive Order does not conflict with section 109 of the Act because the requirement that agencies ''select approaches that maximize net benefits'' does not apply if a ''statute requires another regulatory approach.'' Executive Order 12866, section (1)(a), (58 FR 51735, October 4, 1993). More generally, the Executive Order provides that agencies are to adhere to its regulatory principles only ''to the extent permitted by law.'' *Id.*, section (1)(b).

UMRA sections 202 and 205 do not apply to this decision, as discussed in Unit VIII. of this preamble. Even when they do apply to a regulatory action, they do not establish decisional criteria that an agency must follow, much less override decisional criteria established in the statute authorizing the regulatory action. UMRA does not require an agency to select any particular alternative. Rather, an agency can select an alternative that is not the least costly, most cost-effective or least burdensome if the agency explains why. Section 205(b)(1) of UMRA. Such an explanation is not required if the least costly, most cost-effective or least burdensome alternative would have been ''inconsistent with law,'' section 205(b)(2) of UMRA, and the only alternatives that an agency should consider are ones that ''achieve[] the objectives of the rule,'' section 205(a) of UMRA. The UMRA Conference Report confirms that UMRA does not override the authorizing statute. ''This section [202] does not require the preparation of any estimate or analysis if the agency is prohibited by law from considering the estimate or analysis in adopting the rule.'' 141 Cong. Rec. H3063 (daily ed. March 13, 1995).

The RFA (as amended by SBREFA) also does not apply to this decision, as

[82] See 647 F.2d at 1148–51. By contrast, the commenter's argument that Congress actually intended EPA to consider such factors relies heavily on statements made in subsequent legislative history, most of which were made in floor debate, that sought to justify controversial amendments to establish a different program than the NAAQS and did not involve any proposed changes in section 109 of the Act or related provisions; and statements in early judicial decisions involving programs under other statutory provisions. In context, EPA determines these and other statements cited by the commenter are consistent with and do not alter the conclusion that Congress intended to preclude consideration of costs and similar factors under section 109 of the Act.

[83] The commenter argues that the post-Chevron cases accepted the Lead Industries analysis uncritically rather than re-examining it under Chevron. Clearly, this elevates form over substance. It is true that neither case referred to Chevron in discussing the point at issue. In Vinyl Chloride, however, the Court retraced the steps in the Lead Industries analysis in some detail, characterized some of the key evidence reviewed in that analysis in terms going beyond mere rote repetition (e.g., ''a far clearer statement than anything in the present case that Congress considered the alternatives''), and used Chevron-like language in discussing the significance of that evidence; that is, that it demonstrated congressional intention on the point at issue. E.g., 824 F.2d at 1159. Given that the Vinyl Chloride case was decided three years after Chevron, that it was an en banc decision of the D.C. Circuit involving interpretation of statutory language very similar to that in Lead Industries, and that the Court cited Chevron twice in analyzing the language and history of section 112 of the Act, it seems highly unlikely that the Court was unmindful of Chevron principles in concluding that Congress intended to preclude consideration of costs under section 109 of the Act but not under section 112 of the Act.

In the PM_{10} decision, the Court confirmed the sharp distinction it had drawn, based on such evidence of congressional intent, between sections 109 and 112 of the Act in Vinyl Chloride. 902 F.2d at 972–973. Although discussion of the point was brief and did not mention Chevron, the industry petitioner raising the point had cited Chevron in arguing that the Lead Industries interpretation was not binding, and that EPA's decision on the PM_{10} standards should be reversed on the ground that it rested on a legal position that EPA unjustifiably believed was mandated by Congress. Reply Brief of the American Iron and Steel Institute at 11 and n.10, *Natural Resources Defense Council* v. *Administrator*, 902 F.2d 962 (D.C. Cir. 1990) (Nos. 87-1438 et al.). Thus, Chevron issues were properly before the Court and were brought squarely to its attention.

[84] See also 52 FR 24854, July 1, 1987.

discussed in Unit VIII. of this preamble. As is the case with UMRA, even when the RFA (as amended by SBREFA) does apply to a regulatory action, it does not establish decisional criteria that an agency must follow, much less override the underlying substantive statute. When the RFA was adopted in 1980, Congress made clear that it did not alter the substantive standards contained in authorizing statutes: ''The requirements of section 603 and 604 of this title [to prepare initial and final regulatory flexibility analyses] do not alter in any manner standards otherwise applicable by law to agency action.'' Section 606 of the RFA. The legislative history further explains that section 606 ''succinctly states that this bill does not alter the substantive standard contained in underlying statutes which defines the agency's mandate.''[85] When Congress passed SBREFA in 1996 and amended parts of the RFA, it did not amend section 606.

Even when a regulatory decision is subject to sections 603 and 604 of the RFA and an agency is therefore required to analyze alternatives that minimize significant economic impacts on small entities, the RFA (as amended by SBREFA) does not establish decisional criteria that an agency is required to follow. Both section 603 and 604 of the RFA provide that the alternatives an agency should consider are to be ''consistent with the stated objectives of applicable statutes.'' Section 603(c) and 604(a)(5) of the RFA. Furthermore, although the RFA (as amended by SBREFA) requires agencies to consider alternatives that minimize impacts on small entities subject to the rules' requirements and to explain their choice of regulatory alternatives, it does not require agencies to select such alternatives. For these reasons, the RFA (as amended by SBREFA) does not conflict with or override the Clean Air Act's preclusion of considering costs and similar factors in setting NAAQS.

3. *Conclusion.* In summary, EPA determines that the judicial decisions cited in this unit are both correct and dispositive on the question of considering costs in setting NAAQS, and that the Agency is not free to reinterpret the Act on that question.

B. Margin of Safety

Several commenters questioned the approach used by the Administrator in specifying PM standards that protect public health with an adequate margin of safety. Rather than the integrative approach applied by the Administrator, these commenters maintained that EPA must employ a two-step process. One line of argument was that the Administrator must first determine a ''safe level'' and then apply a margin of safety taking into account costs and societal impacts. It was argued that this was the only approach that would enable the Administrator to reach a reasoned decision on a standard level that protects public health against unacceptable risk of harm, such that any remaining risk was ''acceptable.'' In effect, these commenters adopted the two-step methodology endorsed by Vinyl Chloride, 824 F.2d 1146, for setting hazardous air pollutant standards under section 112 of the Act. Another commenter also maintained that the Administrator must apply a two-step process but from a different perspective. It was argued that EPA should first identify the lowest observed effect level and then apply a margin of safety to address uncertainties and to protect the most sensitive individuals within the at-risk population(s). This commenter also maintained that the use of risk assessment in establishing a NAAQS was a departure from past practice, and that this departure was not adequately explained.

In recognition of the complexities facing the Administrator in determining a standard that protects public health with an adequate margin of safety, the courts have declined to impose any specific requirements on the Administrator's methodological approach. Thus, in Lead Industries the court held that the selection of any particular approach to providing an adequate margin of safety ''is a policy choice of the type Congress specifically left to the Administrator's judgment. This court must allow him the discretion to determine which approach will best fulfill the goals of the Act.'' 647 F.2d at 1161–1162. As a result, the Administrator is not limited to any single approach to determining an adequate margin of safety and, in the exercise of her judgment, may choose an integrative approach, a two-step approach, or perhaps some other approach, depending on the particular circumstances confronting her in a given NAAQS review.

With respect to the approaches advanced in comment, the PM_{10} case made clear that the two-step process endorsed in Vinyl Chloride was necessary because of the need under section 112 of the Act to ''sever determinations that must be based solely on health considerations from those that may include economic and technical considerations.'' 902 F.2d at 973. Because the Administrator may not consider cost and technological feasibility under section 109 of the Act, however, the Court concluded that ''the rationale for parsing the Administrator's determination into two steps is inapposite.'' *Id.*

The claim that EPA must follow a two-step process of first identifying the lowest observed effects level and then applying a margin of safety has also been rejected by the courts. In Lead Industries, the Court specifically held that the Administrator need not apply a margin of safety at the end of the analytical process but may take into account margin of safety considerations throughout the process as long as such considerations are fully explained and supported by the record. 647 F.2d 1161–1162. Accord, PM_{10}, 902 F.2d at 973–974.

Because such factors as the nature and severity of the health effects involved, the size of the sensitive population(s) at risk, the types of health information available, and the kind and degree of uncertainties that must be addressed will vary from one pollutant to another, the most appropriate approach to establishing a NAAQS with an adequate margin of safety may be different for each standard under review. Thus, no generalized paradigm such as that imbedded in EPA's cancer risk policy can substitute for the Administrator's careful and reasoned assessment of all relevant health factors in reaching such a judgment. As noted in this unit, both Congress and the courts have left to the Administrator's discretion the choice of analytical approaches and tools, including risk assessments, rather than prescribing a particular formula for reaching such determinations.[86] Because of the inherent uncertainties that the Administrator must address in margin of safety determinations, they are largely judgmental in nature, particularly with respect to non-threshold pollutants, and may not be amenable to quantification in terms of what risk is ''acceptable'' or any other metric. In view of these considerations, the task of the Administrator is to select an approach that best takes into account the nature of the health effects and other information assessed in the air quality criteria for the pollutant in question and to apply appropriate and reasoned analysis to ensure that scientific

[85] 126 Cong. Rec. 21452, 21455 (1980) (Description of Major Issues and Section-By-Section Analysis of Substitute for S. 299).

[86] Contrary to one of the comments received, EPA's use of risk assessment in this rulemaking is by no means a departure from past practice. The EPA first considered and began applying risk assessment methods in the late 1970's (44 FR 8210, 8211, February 8, 1979).

uncertainties are taken into account in an appropriate manner.

In this instance, the Administrator has clearly articulated the factors she has considered, the judgments she has had to make in the face of uncertain and incomplete information, and alternative views as to how such information should be interpreted, in reaching her decision on standard specifications that will protect public health with an adequate margin of safety. See Unit II. of this preamble. Her conclusions on these matters are fully supported by the record.

C. Data Availability

Several commenters questioned EPA's ability to rely on studies demonstrating an association between PM and excess mortality without obtaining and disclosing the raw ''data'' underlying these studies for public review and comment. In particular, a number of commenters cited Dockery, D.W., et al. 1993 and Pope, C.A. III, et al., 1995, as studies upon which EPA relied without obtaining and disclosing the underlying raw data. One commenter also cited J. Schwartz et al., 1996 in the same context.[87] According to the commenters, without the underlying data used in these studies, the reliability of these studies cannot be assessed accurately. These commenters requested that EPA obtain the relevant data and make it available for public review. In light of the court-ordered requirement that EPA publish its rule by July 19, 1997, the commenters argued that EPA must retain the current PM_{10} NAAQS pending additional review of the raw data and the studies at issue. One commenter, the American Petroleum Institute (API) requested that EPA remove the studies from the docket, unless the underlying data was also included in the docket.[88]

A few commenters argued that section 307(d) of the Act requires that EPA obtain the raw data underlying these studies and that a failure to do so contradicts the plain language of section 307(d)(3) of the Act, which requires EPA to place in the docket any ''factual data on which the proposed rule is based.'' Other commenters argued that under section 307(d)(8) of the Act, a failure to obtain and disclose the underlying raw data used in the studies would constitute an error ''so serious and related to matters of such central relevance to the rule that there is a substantial likelihood that the rule would have been significantly changed if such errors had not been made.'' *Id.* According to one commenter, without the raw data and an opportunity for an analysis of it, ''EPA has no legal alternative other than to conclude that no new air quality standard would be appropriate within the meaning of CAA section 109(a)(1)(B).'' Finally, a number of commenters have argued that recent caselaw under the Clean Air Act and other statutes makes clear that EPA has a legal obligation to obtain and disclose the data used in these studies.[89]

In developing the proposed revisions to the PM NAAQS, the Administrator relied on the scientific studies cited in the rulemaking record, rather than on the raw data underlying them.[90] In this case, the raw data consists of responses to health questionnaires based on information supplied by individual citizens, or computer tabulations of this information, which remains confidential, and air quality and monitoring data, most of which is now publicly available. EPA does not generally undertake evaluations of raw, unanalyzed scientific data as part of its public health standard setting process. Only in extreme cases—for example where there are credible allegations of fraud, abuse or misconduct—would a review of raw data be warranted. It would be impractical and unnecessary for EPA to review underlying data for every study upon which it relies as support for every proposed rule or standard. If EPA and other governmental agencies could not rely on published studies without conducting an independent analysis of the enormous volume of raw data underlying them, then much plainly relevant scientific information would become unavailable to EPA for use in setting standards to protect public health and the environment. In addition, such data are often the property of scientific investigators and are often not readily available because of the proprietary interests of the investigators or because of arrangements made to maintain confidentiality regarding personal health status and lifestyle information of individuals included in such data. Without provisions of confidentiality, the possibility of conducting such studies could be severely compromised.[91]

In this case, the merits of the studies considered and used in developing the $PM_{2.5}$ standard have been discussed and debated extensively over the past several years, both as part of the EPA review of the pertinent science and in a number of other public forums. The studies at issue were critically evaluated

[87] Contrary to this commenter's assertion, both the health and air quality data used in the 1996 Schwartz study are available to interested parties. EPA's Office of Research and Development maintains a copy of the air pollution database used in the Schwartz study and it has previously been made available in response to Freedom of Information Act requests from interested parties, such as the American Iron and Steel Institute (AISI). The Harvard School of Public Health has also made this data available to several collaborators and to the Health Effects Institute. With regard to the health data underlying the Schwartz study, that mortality data was compiled by the National Center for Health Statistics (NCHS) and can be purchased from the NCHS by interested parties. Thus, there is no real data availability concern with regard to the 1996 Schwartz study. However, even were this not the case, for the reasons discussed more fully in this unit and elsewhere in the preamble, EPA believes it would be entitled to rely upon this study and other studies, including the Dockery and Pope studies, regardless of the availability of the underlying health data.

[88] API's letter stated that ''API petitions EPA to identify all studies that rely, in any way, on data not available for public review as part of the rulemaking process and remove those studies from the record.'' To the extent this letter constitutes a ''petition'' for EPA action, EPA hereby denies the ''petition'' for the reasons stated in this unit and elsewhere in this preamble.

[89] One commenter argued that the failure to obtain and disclose the underlying data was a violation of the Administrative Procedure Act (APA). The NAAQS rulemaking is promulgated under section 307(d) of the Act; the APA generally does not apply to such rulemakings. See section 307(d)(1) of the Act.

[90] It is important to note that while EPA did use the Dockery and Pope studies to confirm its conclusions regarding the health effects of fine particulate air pollution and thus as support for its decision to revise the PM standard, these studies do not provide the sole (or even primary) basis for EPA's decision regarding $PM_{2.5}$, despite the assertions of numerous commenters. The proposed standards are based on a consideration of a large body of epidemiological studies, a clear majority of which suggest PM is strongly linked to mortality and other serious health effects at concentrations permitted under the current standards. Although the specific levels of the $PM_{2.5}$ standards are based on a more limited number of studies that actually measured fine particles and/or components of fine particles, the Dockery and Pope studies were not used in initially selecting the annual fine particle standard level, which was principally based on examination of other daily mortality and respiratory effects studies (Koman, 1996, 1997) that found significant associations between fine PM and effects in cities with annual average $PM_{2.5}$ concentrations of about 16 to 21 μg/m3. Only then were the long-term Dockery and Pope studies examined and used to help corroborate this result; in the opinion of the Administrator, neither study alone (or together) provided sufficient evidence to support more stringent levels below those identified from the daily studies. Thus, removal of the Dockery and Pope studies would not affect the conclusions about the significance of the risks and therefore, while these long-term studies tend to strengthen the need for fine particle control and provide important insights into the nature of PM effects, removal of these two studies from consideration would not have changed the selected standard level.

[91] Some commenters noted that with regard to the health data underlying the 1993 Dockery and 1995 Pope studies, since EPA provided partial funding for these studies, EPA has access to this data and cannot shield itself from the duty to obtain this data by claiming that it is not in its possession. Although a legal argument potentially exists that EPA may obtain access to such data, this legal argument has not been tested in the courts. More importantly, EPA's ability to rely on studies without reviewing the raw data should not depend on whether some Agency of the Federal government funded the science.

by the Agency's Office of Research and Development (ORD) and by the EPA's independent Clean Air Scientific Advisory Committee (CASAC), in a multi-year process for assessment of the science at issue. As with other studies on which EPA relied, particular attention was given to the strengths and limitations of the Dockery, Schwartz and Pope studies during this process, which involved numerous opportunities for public participation and extensive input from interested parties. The results of these studies are not only consistent with each other, but they are also consistent with the results of other studies demonstrating significant associations between long-term exposure to fine particle indicators and mortality. See U.S. EPA, 1996b, p. V–62. The CASAC concluded that EPA's assessments of the pertinent science properly characterized both the current state of knowledge and the range of policy options for revising the standards.

In fact, many peer reviewed studies have reported associations between PM and premature death; the Dockery, Schwartz and Pope studies are among the most recent studies to corroborate this association. In the early 1990s, several studies were published showing associations at levels below the current PM standards. Some critics began raising questions about the extent to which the results could be reproduced and the unavailability of underlying data. In response, an independent group of investigators under the auspices of the Health Effects Institute (HEI), a highly respected research organization jointly funded by EPA and several motor vehicle manufacturers, undertook a reanalysis of several such studies. The original investigators of several studies, including studies conducted at Harvard University, Brigham Young University, and the San Francisco Bay Area Air Quality Management District provided their raw air quality data sets to the HEI investigation team for reanalysis. HEI's reanalysis produced numerical results from the data sets for all six cities that closely agree with and, in general, confirm the results of the original investigators. Thus, as noted in Unit II. of this preamble, these reanalyses by respected independent scientists confirmed the reliability and reproduceability of prior work of the original investigators, including work by Dockery et al. (1992), Pope et al. (1992), Schwartz and Dockery (1992a), and Schwartz (1993).

Thus, the 1993 Dockery and 1995 Pope studies build upon previous studies done by a number of different researchers and have been subject to an extensive peer review process by EPA's ORD, CASAC and HEI. They also underwent a peer review process at the time of their publication in reputable scientific journals. Given the consistency and coherence of the scientific evidence and the scrutiny the studies have received in peer review and in the extensive scientific review process described in this unit, EPA does not agree that review of the underlying data for these studies is also necessary. Considering the various reviews described in this unit and the fact that EPA has received no specific and substantiated reason, such as plausible allegations of fraud or scientific abuse, to doubt the overall validity of their conclusions, EPA agrees with CASAC that revision of the standard is appropriate, based on these and other studies.

In spite of EPA and CASAC's conclusion that it is appropriate to rely on the Pope, Dockery and other studies to establish a $PM_{2.5}$ NAAQS, EPA also believes in public disclosure and supports efforts to seek appropriate release of data underlying the studies in question. On January 31, 1997, EPA wrote to the principal scientific investigators at the Harvard School of Public Health and at Brigham Young University and urged them to make the data associated with their studies available to interested parties. Studies conducted by these investigators relied on data compiled as part of the Harvard Six-Cities Study and data compiled by the American Cancer Society (ACS) as part of the Cancer Prevention Study II.

The studies in question combined health data on individuals with air pollution data. The air pollution data are publicly available. The health data consist of personal and confidential information, e.g. age, sex, weight, eduction level, smoking history, occupational exposures, medical history. These data are not publicly available. In compiling these data, researchers have promised study participants that private, personal information would be kept confidential under signed assurances of confidentiality. Data-sharing arrangements with outside parties must, therefore, accommodate interests both in making data accessible and in protecting the confidentiality of the information contained within them.

Both the Harvard School of Public Health and the American Cancer Society have made such arrangements. Both have processes which allow ouside scientists, in collaboration with Harvard and ACS researchers, to access their databases for the conduct of legitimate scientific research. Scientists from all over the world have applied for and have been granted such access and numerous studies have been conducted and published using the databases.

Because of increased interest resulting from EPA's rulemaking on PM standards and at the request of the Harvard School of Public Health, HEI is taking additional steps to provide a forum for outside researchers to access health data associated with the Harvard-Six Cities Study and perhaps others. HEI has convened an expert panel of esteemed scientists to access underlying data and to conduct additional reanalyses. This arrangement appears to provide a constructive venue for testing legitimate scientific hypotheses while protecting the confidentiality of the underlying data.

Nevertheless, as noted previously, EPA has full confidence in the scientific integrity of the Dockery, Schwartz, and Pope studies and their suitability for use in the Agency's rulemaking on PM, without undertaking a separate or additional review and analysis of the underlying raw data. The decision to propose revisions of the current PM standards was based on careful assessment of the scientific and technical information presented in the PM Criteria Document and Staff Paper. The decision was also consistent with the consensus of CASAC that ''although an understanding of health effects of PM is far from complete, the Staff Paper, when revised, will provide an adequate summary of our present understanding of the scientific basis for making regulatory decisions concerning PM standards.'' The extensive PM epidemiological data base provides evidence that serious adverse health effects, e.g., mortality, exacerbation of chronic disease, increased hospital admissions, respiratory symptoms, and pulmonary function decrements, in sensitive subpopulations, e.g., the elderly, individuals with cardiopulmonary disease and children, are attributable to PM at levels below the current standards. The increase in risk is significant from an overall public health perspective because of the large number of individuals in sensitive subpopulations that are exposed to ambient PM and the significance of the health effects. These considerations, as well as others discussed in the proposal and Staff Paper, such as the need to consider fine and coarse particles as distinct classes, led both the Administrator and CASAC to conclude that revision of the current standards is clearly appropriate. This conclusion remains unchanged despite the fact that EPA is without the actual raw and

unanalyzed health data underlying the studies.

A number of commenters cited section 307(d) of the Act in support of their position that EPA is required to obtain and disclose the underlying raw data. Under section 307(d)(3) of the Act, EPA is required to issue a notice of proposed rulemaking in the **Federal Register** that is accompanied by a ''statement of basis and purpose'' that includes ''a summary'' of:

(A) The factual data on which the proposed rule is based.

(B) The methodology used in obtaining the data and in analyzing the data.

Thus, it is clear from the language of section 307(d) of the Act that where EPA relies on any ''data'' as support in its rulemakings under the Clean Air Act, it has an obligation to include such data or information in the rulemaking docket that is open to the public. Where EPA fails to do so and the error is ''so serious and related to matters of such central relevance to the rule that there is a substantial likelihood that the rule would have been significantly changed if such errors had not been made,'' a reviewing court may overturn the rule.

In this case, as noted previously, EPA did not rely upon the raw health data supporting the Dockery and Pope studies; it relied instead upon the studies themselves. These studies may properly be considered ''data.'' The EPA has never had the raw health data in its possession; thus EPA has neither reviewed it nor had an opportunity to place it in the docket. The EPA did rely on the studies and these studies are included in the docket and are available for public review. Because EPA neither reviewed nor relied upon the raw data, there is no obligation to obtain it or to make it available.

Some commenters argued that the language of section 307(d) of the Act, which refers to the ''factual data'' and which also discusses the ''methodology used in obtaining and analyzing the data'' distinguishes between raw data and studies. In the view of these and other commenters, the plain language of section 307(d) of the Act requires that EPA obtain and disclose the raw data used in the Dockery and Pope studies. According to these commenters, without such raw ''data,'' EPA cannot legally promulgate its rule.

The EPA disagrees with this narrow interpretation of the word ''data'' and of section 307(d) of the Act. Data can take many forms, including studies, reports, tabulations, graphs and summaries, as well as more raw forms, such as questionnaire responses, test results and even actual physical specimens. The ''factual data'' called for by section 307(d) of the Act may clearly include peer-reviewed scientific studies. Nor does section 307(d) of the Act prohibit EPA from relying on a study for standard setting without obtaining the raw, underlying data supporting a study. Indeed, as noted in the legislative history to section 307(d) of the Act,

> * * * [t]he [House Commerce] Committee recognizes that the factual support needed for a rule may vary greatly according to the subject being addressed and that rules on some subjects, such as procedures, may not require any factual basis at all. There is no intention to increase the amount of 'factual' support now required to support 'policy judgments where no factual certainties exist or where facts alone do not provide the answer,' Industrial Union Department, *AFL-CIO* v. *Hodgson*, 499 F.2d 467, 476 (D.C. Cir. 1974). Nor is there any intent to diminish the Administrator's authority to adopt precautionary regulations based on a showing of risk * * * .

H.R. Rep. No. 95-294, at 323 (1977) (footnote omitted). As this legislative history makes clear, the language in section 307(d) of the Act is not intended to require EPA to change the amount of ''factual support'' that EPA must assemble in order to promulgate a rule and EPA may adopt ''precautionary'' regulations ''where no factual certainties exist.'' Given this clarification in the legislative history, it is evident that EPA is entitled under section 307(d) of the Act to rely on studies rather than raw data in developing its Clean Air Act rules, despite the arguably ambiguous use of the term ''data.''[92]

Moreover, EPA has relied on studies in the past (including studies using the undisclosed Six Cities data) without obtaining or disclosing the underlying raw data, and EPA's reliance on such studies to set Clean Air Act standards has been upheld in court. In *NRDC* v. *EPA*, 902 F. 2d 962 (D.C. Cir. 1990), the D.C. Circuit declined to delay its review of the PM_{10} NAAQS rulemaking due to concerns raised by the American Iron and Steel Institute about the integrity of the Six Cities data base. 902 F.2d at 974. In that case, EPA had relied upon an earlier Dockery study based on the Six Cities data base. Although the National Institutes of Health (NIH) undertook a review of the allegations regarding the Six Cities database, the court nevertheless upheld EPA's reliance on that Dockery study without waiting for the results of the NIH review. NIH eventually concluded that the allegations were without merit. According to the court in the NRDC case:

> AISI claims that the EPA relied *too much* on the Six Cities Study, which is comprised of the Dockery study and the Ware study * * * . We do not agree that the Administrator's selection of the twenty-four hour standard lacks the necessary reasoned analysis and supportive evidence * * * . After carefully reviewing the record, we find EPA's selection of the twenty four hour standard reasonable in light of the divergent results in the studies and the agency's mandate to provide an adequate margin of safety. Studies contained in the record provided evidence of adverse health effects at levels below 250 μg/m3.

902 F.2d at 969 (footnotes omitted; *emphasis in original*). The court also stated that:

> In setting a standard under section 109 of the Act, the Administrator must ''take into account all the relevant studies revealed in the record'' and ''make an informed judgment based on available evidence.'' *American Petroleum Institute* v. *Costle*, 665 F.2d at 1187. The record shows that the Administrator did so. The Administrator relied on studies which showed adverse effects at and below the 250 μg/m3 level. AISI essentially asks this court to give different weight to the studies than did the Administrator. We must decline. It is simply not the court's role to ''second-guess the scientific judgments of the EPA. * * * [T]he Administrator did not act arbitrarily in drawing conclusions from the uncertain and conflicting data. The Administrator may reasonably apply his expertise to draw conclusions from ''imperfect data,'' Ethyl Corp., 541 F.2d at 28, as he did here.

Id. at 971.

As this language makes plain, the term ''data'' may include a study relied upon by EPA. It should be equally plain that EPA may properly rely on such a study in setting a standard despite the fact that such ''data'' may be ''imperfect,'' ''conflicting,'' and ''uncertain.'' There are numerous other cases in which EPA has relied on studies in setting standards under the Clean Air Act. See, e.g., *Engine Manufacturers Association* v. *EPA*, 88 F. 3d 1075, 1099 (D.C. Cir. 1996)(upholding EPA's use of the 1993 Dockery study for setting mobile source standards); *API* v. *Costle*, 665 F.2d 1176, 1185 (D.C. Cir. 1981)(Administrator's conclusion that normal body functions

[92] EPA also does not agree that because the language of section 307(d) of the Act mentions ''factual data'' as well as ''the methodology used in obtaining and analyzing the data,'' EPA cannot rely on a study alone. In this case, the study is the ''factual data'' and EPA's methodology used in obtaining and analyzing the ''factual data'' is the method that EPA used to review and rely upon the studies. This methodology is discussed extensively in the staff paper and summarized in some detail elsewhere in this preamble. In fact, as is clear from the overall structure of section 307(d) of the Act, as well as the legislative history cited in this unit, section 307(d) of the Act merely requires that EPA summarize and disclose the information and methodology that it relied upon in developing its rule. It leaves unchanged the ''level'' of support that an agency must bring to bear in drafting a proposed rule.

are disrupted by ozone is ''supported by the studies'').

A number of commenters cited *Endangered Species Committee* v. *Babbitt,* 852 F. Supp. 32 (D.D.C. 1994) (hereafter ''Gnatcatcher'') in support of the proposition that EPA must obtain and disclose the raw data underlying the Dockery and Pope studies. Relying on cases such as *Connecticut Light and Power Co.* v. *NRC,* 673 F.2d 525 (D.C. Cir. 1982), *Portland Cement* v. *Ruckelshaus,* 486 F.2d 375 (D.C. Cir. 1973), and *United States* v. *Nova Scotia Food Processing Corp,* 568 F.2d 240 (2nd Cir. 1977), these commenters suggest that ''a body of legal decisions is emerging whereby federal courts are increasingly dubious of final regulatory decisions that are being made absent public scrutiny of the data underlying and purportedly supporting such decisions.'' According to these commenters, based on Gnatcatcher and other cases, failure by EPA to obtain and place in the docket the raw unanalyzed data used in the Dockery and Pope studies constitutes serious procedural error under the Clean Air Act.

Under Connecticut Light and Power, agencies must make available technical studies and data that have been relied upon during the rulemaking process in order for the public to have an adequate opportunity for notice and comment. There is no question that EPA has done this with regard to the Dockery and Pope studies, which are included in the rulemaking docket. The Portland Cement case makes clear that where an agency actually relies on factual data it cannot ''promulgate rules on the basis of inadequate data, or on data that, [to a] critical degree, is known only to the agency.'' 486 F.2d at 393. See also, Nova Scotia, 568 F.2d 240, at 251 (where all of the research was collected by the agency, and none of it was disclosed ''as the material upon which the proposed rule would be fashioned,'' error resulted); *CMA* v. *EPA,* 870 F.2d 177, 200 (5th Cir. 1989) (''fairness requires that the agency afford interested parties an opportunity to challenge the underlying factual data relied on by the agency'').

However, in this case, EPA did not rely on, nor did it ever have or review, the underlying data used in the Dockery and Pope studies. Instead, it relied upon the studies themselves. Thus, the cases cited in this unit are inapposite. They stand only for the proposition that where an agency actually reviews and relies on ''data,'' which may be raw data, a study or a variety of other forms of information, it must make these data available. They do not and cannot stand for the proposition that an agency may not rely on a study alone and must always obtain the raw and unanalyzed data underlying a study. Indeed, as one D.C. Circuit case noted: ''Portland Cement and Nova Scotia simply cannot be twisted so as to require notices of proposed or interim rules to contain elaborate reproductions of underlying studies.'' *Petry* v. *Block,* 737 F.2d 1193, 1198 (D.C. Cir. 1984). Requiring EPA to obtain, analyze and disclose the data underlying the Pope and Dockery studies, which EPA neither reviewed nor relied upon, would be to require EPA to attempt such an ''elaborate reproduction.'' Such a step is not required under the law and would make it extremely difficult, if not impossible, for EPA to regulate in complex, technical areas ''at the frontiers of science.'' *Baltimore Gas and Electric Co.* v. *NRC,* 462 U.S. 87 (1983).

The district court's decision in the Gnatcatcher case is similarly inapposite. That case concerned a scientific study regarding the range of the California Gnatcatcher, a small insectivorous songbird. As the Gnatcatcher opinion itself notes, ''courts have generally allowed agencies to rely on scientific reports.'' Gnatcatcher, 852 F.Supp. at 37. Thus, the question at issue in Gnatcatcher was whether specific circumstances exist in which an agency may not be entitled to rely on studies alone. In the Gnatcatcher case, a single author had published two directly contradictory studies on the same issue, while relying on the same data. In light of this clear contradiction, commenters in that rulemaking argued that without the underlying data it was impossible to determine whether the conclusions in either study were correct. The district court noted that:

> The Secretary had before him a report by an author who, two years before had analyzed the same data and come to an opposite conclusion. It is the disputed nature of this report that distinguishes this from other cases where a scientific report alone has been considered sufficient for ESA purposes.

Id. Thus, according to the court: ''While courts have generally allowed agencies to rely on scientific reports * * * this is not sufficient in this case because the report itself is under serious question.'' *Id.*

The EPA's current reliance on the Dockery and Pope studies bears no resemblance to the circumstances present in the Gnatcatcher decision. As noted previously, these studies have been subject to extensive peer review and scrutiny, and neither researcher has published a contradictory study on the same issue, much less using the same data base. The EPA is not aware of, nor have any of the commenters raised any particular issues relating to either gross error, fraud or scientific abuse arising from the data. Indeed, as noted previously, the prior work of these particular researchers has been subject to extensive independent scrutiny and reanalysis, which has confirmed, rather than called into question, the underlying validity of their conclusions and the integrity of their research methods. Reading Gnatcatcher to suggest that EPA cannot rely on such a study, where the study and its methods have been subject to extensive peer review, would place the district court's rationale in Gnatcatcher in conflict with applicable D.C. Circuit precedent that makes evident the right of agencies to rely on studies alone. See, e.g., *Engine Manufacturers Association* v. *EPA,* 88 F.3d 1075, 1099 (D.C. Cir 1996); *API* v. *Costle,* 665 F.2d 1176, 1185 (D.C. Cir. 1981), ''studies discussed in the Criteria Document constitute a rational basis for the finding that adverse health effects occur at ozone levels of 0.15-0.25 ppm for sensitive individuals''; see also, *NRDC* v. *Thomas,* 805 F.2d 410, 418 (D.C. Cir. 1986)(EPA use of a summary of confidential data that was not disclosed provides ''a reasoned explanation for moving from a 4.0 to 5.0 long term NOx standard'').

In addition, to require EPA to obtain and analyze the data prior to revising the standard would also contradict the ''common sense notion that Congress, in providing for notice and comment under the APA, could not have intended to subject the agencies—and the public on whose behalf they regulate—to [a] sort of interminable back and forth.'' *International Fabricare Institute* v. *EPA,* 972 F.2d 384, 399 (D.C. Cir. 1992). In the view of some commenters, EPA has no choice but to either postpone its decision for a year or more awaiting a review of data or choose to retain the current standard. Yet were EPA to adopt such an approach, these commenters would undoubtedly insist that EPA be required to include an analysis of the data in the docket; further questions would likely be raised regarding the re-analysis and once again EPA might find itself unable to promulgate its rule pending review of further hypothetical questions. This type of unending inquiry is not required under the law. As the D.C. Circuit has noted:

> * * * [D]isagreement among the experts is inevitable when the issues involved are at the ''very frontiers of scientific knowledge,'' and such disagreement does not prevent us from finding that the Administrator's decisions are adequately supported by the evidence in the record * * * . It is not our function to resolve disagreement among the experts or to judge

the merits of competing expert views * * * . Cf. *Hercules, Inc.* v. *EPA,* 598 F.2d 91,115 (D.C. Cir. 1978) (''[c]hoice among scientific test data is precisely the type of judgment that must be made by EPA, not this court'').

Lead Industries Association v. *EPA,* 647 F.2d 1130, 1160 (D.C. Cir. 1980).

Neither Gnatcatcher, nor any other case can fairly be read to suggest that EPA has an obligation to respond to all possible questions that might be raised regarding its scientific conclusions or that where EPA relies on a study, it must engage in a multi-phased and possibly unending re-examination of the data supporting such a study until all commenters are satisfied in full with the details of the underlying science. Even assuming that EPA could obtain the confidential Six Cities data through litigation, a substantial delay of many months, if not years, would likely result, in order for both EPA and industry to reanalyze the data. In the meantime, some tens of thousands of premature deaths could result. Neither the Clean Air Act nor relevant case law requires or permits such a result.

Indeed, the suggestion that EPA cannot and should not rely upon the Pope, Dockery, and Schwartz studies, unless and until interested parties have had an opportunity to examine and reanalyze the underlying raw data, is extraordinary. Given the precautionary nature of section 109 of the Act and the need to allow an adequate margin of safety, see Lead Industries, 647 F.2d at 1154, 1155, there are limits on EPA's discretion to disregard even studies that are clearly flawed, if they are nonetheless ''useful'' in indicating the kind and extent of health effects that may result from the presence of a pollutant in the ambient air. See sections 109(b)(1) and 108(a)(2) of the Act.

A few commenters cited *Kennecott* v. *EPA,* 684 F.2d 1007 (D.C. Cir. 1982) and argued that under sections 307(d)(8) and 307(d)(9)(D) of the Act, a failure by EPA to obtain and include in the docket the data underlying the Pope and Dockery studies would constitute an ''error'' that is ''so serious and related to matters of such central relevance to the rule that there is a substantial likelihood that the rule would have been significantly changed if such error[] had not been made.''[93] EPA disagrees. Peer reviewed studies conducted by outside parties were not at issue in Kennecott. Kennecott involved a dispute over financial analyses that EPA itself had previously conducted and used in earlier rulemakings. The court determined that the financial analyses at issue must have provided at least part of the factual basis for EPA's rule, and EPA referenced these analyses in the preamble to the final rule without placing them in the docket until one week before promulgation. The factual circumstances in Kennecott are substantially different than the current situation and thus, Kennecott cannot fairly be read to establish the applicable legal standard with regard to EPA's reliance on peer reviewed studies for use in setting the NAAQS.

In this case, EPA—well before proposal—has placed the information that it relied upon in the docket. This information is in the form of studies. These studies have been subject to extensive scrutiny and peer review. To date no specific allegation has been made that the studies are clearly in error or that the data underlying them are the subject of fraud, scientific misconduct, or gross error going to the basic validity of the studies.[94] Instead, various commenters have merely stated their view that were the raw data behind these studies available, they would be able to better verify and assess the results reached in the studies.

As one commenter noted, ''In the absence of data on which EPA's proposal is based, [key scientific] issues remain shrouded in uncertainty and skepticism. The disclosure of the data would allow for robust scientific analysis and discussion of these issues.'' A similarly hypothetical concern is raised by another commenter who stated that ''seeing the data would clarify substantial questions of methodology'' and ''had the Harvard data been available, a far broader evaluation of the defects of the Harvard Studies would have been possible with the same expenditure of time and money.'' Yet, despite having spent ''in the neighborhood of a million dollars to duplicate and reanalyze the Harvard data set'' this commenter was unable to allege any particular defect in the methodology or results of these studies and noted instead that ''the track record to date suggests that the claimed associations to $PM_{2.5}$ and health effects would not have held up under such a broader evaluation.''

EPA is not required to await the results of such an inquiry before proceeding to regulate to protect human health and the environment. The concerns raised by the commenters regarding these studies remain hypothetical; the comments themselves raise no allegations of fraud, scientific misconduct or gross error that calls into question the fundamental validity of the studies. Given this fact, EPA does not agree with the commenters that reliance on these studies and/or a failure to place the underlying data in the docket constitutes an error, much less an error that is ''so serious and related to matters of such central relevance that there is a substantial likelihood that the rule would have been significantly changed.'' EPA is entitled to rely upon these studies and it has satisfied its obligation to provide the ''factual data'' upon which the proposed rule is based by placing these studies in the docket.

In fact, the concerns raised by the commenters ultimately boil down to a disagreement with EPA over the level of scientific certainty necessary to adopt the NAAQS revisions. In setting standards under the Clean Air Act, EPA is not required to resolve all scientific issues to the complete satisfaction of every interested party. As noted by the D.C. Circuit in *Lead Industries Association* v. *EPA,* 647 F.2d 1130, 1160 (D.C. Cir. 1980):

> To be sure, the Administrator's conclusions were not unchallenged; both LIA and the Administrator are able to point to an impressive array of experts supporting each of their respective positions. However, disagreement among the experts is inevitable when the issues involved are at the ''very frontiers of scientific knowledge,'' and such disagreement does not preclude us from finding that the Administrator's decisions are adequately supported by the evidence in the record. It may be that LIA expects this court to conclude that LIA's experts are right, and the experts whose testimony supports EPA are wrong. If so, LIA has seriously misconceived our role * * * . It is not our function to resolve disagreement among the experts or to judge the merits of competing expert views * * * . Cf. *Hercules, Inc.*, v. *EPA,* 598 F.2d 91, 115 (D.C. Cir. 1978) (''[c]hoice among scientific test data is precisely the type of judgment that must be made by EPA, not this court'').

[93] One commenter argued that EPA's failure to place the ''data'' in the docket was not an ''error'' but a ''refusal to comply with the clear language of the law that should be reviewed by the courts under section 307(d)(9)(C), rather than 307(d)(9)(D).'' As noted previously, EPA does not agree with this interpretation of section 307(d)(3) of the Act. Under applicable caselaw, the term ''data'' may include information in many forms, including studies that EPA has placed in the docket. See *Endangered Species Committee* v. *Babbitt,* 852 F. Supp. 32, 37 (D.D.C., 1994) (''data can come in many forms: it can be a scientific report, it can be graphs and tabulations * * * it can be raw numbers'').

[94] A number of commenters did argue these studies do not form a sufficient basis for EPA's decision to revise the NAAQS and that attempts to replicate these studies have not been universally successful. These same commenters also listed a number of hypothetical questions and issues that might be resolved through a review of the underlying data and suggested that before EPA may properly rely on these studies to revise the NAAQS, a variety of confounders (such as smoking) should also be ruled out by reviewing the data. As set forth more fully in Unit II. of this preamble, neither EPA nor CASAC agrees that any of these factors precludes reliance on the studies in question.

647 F.2d at 1160 (footnotes omitted).

The EPA's rationale for proposing to add a fine particle standard was detailed in the preamble to the proposed rule, most notably at 61 FR 65654–65662, December 13, 1996. This decision is based on the extensive review of the science and policy issues contained in the PM Criteria Document and Staff Paper; the CASAC concluded, after extensive review, that both of these documents were appropriate for use in decision making on standards. These documents contain a full discussion of both what is known about PM and the information gaps and uncertainties. Considering the full weight of the scientific evidence, including the uncertainties, the CASAC recommended that the Administrator adopt fine particle standards and a number of panel members based their support for a $PM_{2.5}$ standard on the following reasoning:

> [T]here is strong consistency and coherence of information indicating that high concentrations of urban air pollution adversely affect human health, there are already NAAQS that deal with all of the major components of that pollution except $PM_{2.5}$, and there are strong reasons to believe that $PM_{2.5}$ is at least as important as $PM_{10-2.5}$ in producing adverse health effects.

Wolff, 1996.

Given the consistency and coherence of the evidence that premature mortality and sickness occur in large numbers of Americans at concentrations permitted by the current standards, it would be irresponsible to delay action that would put more appropriate air quality goals into place based on the most recent scientific information. After a review of the comments submitted, the Agency's conclusion that it is appropriate to rely on the existing studies remains unchanged.

D. 1990 Amendments

Contrary to the view expressed in some public comments, the provisions of subpart 4 of Part D of Title I of the Act, enacted in 1990, do not preclude EPA from adopting $PM_{2.5}$ as an additional indicator for PM and establishing standards for $PM_{2.5}$. The provisions of subpart 4 of Part D of Title I of the Act simply do not limit EPA's clear authority under section 109 of the Act to revise the PM standards.

The basic contention is that because the provisions of subpart 4 of Part D of Title I of the Act refer to PM_{10}, they prohibit EPA from regulating any other type of PM, for example, by revising the existing NAAQS for PM by adopting an ambient air quality standard for $PM_{2.5}$. These provisions, however, do not lead to such a conclusion. Moreover, this view ignores provisions indicating that Congress believed that EPA could revise any existing NAAQS or adopt a new NAAQS.

At the outset, it should be noted that Congress expressly authorized EPA to revise any ambient air quality standard and to adopt a new NAAQS in section 109 of the Act. That section, which requires EPA to review and revise, as appropriate, each NAAQS every five years, contains no language expressly or implicitly prohibiting EPA from revising a NAAQS or adopting a new NAAQS. If Congress had intended to preclude EPA from reviewing and revising a NAAQS or adopting a new NAAQS, which are part of EPA's fundamental functions, Congress would have specifically done so. Clearly, Congress knew how to preclude EPA from exercising otherwise existing regulatory authority and did so in other instances. See section 202(b)(1)(C) of the Act (expressly precluding EPA from modifying certain motor vehicle standards prior to model year 2004); section 112(b)(2) of the Act (preventing EPA from adding to the list of hazardous air pollutants any air pollutants that are listed under section 108(a) of the Act unless they meet the specific exceptions of section 112(b)(2) of the Act); section 249(e)(3), (f) and section 250(b) (limiting EPA's authority regarding certain clean-fuel vehicle programs). No such language was included either in section 109 of the Act or elsewhere in the Act and no such implication may properly be based on the provisions of subpart 4 of Part D of Title I of the Act.

Second, other provisions of the Act expressly contemplate EPA's ability to promulgate a new or revised NAAQS, and provide no indication that such ability is limited to standards other than those whose implementation is the subject of subparts 2, 3 and 4 of Part D of Title I of the Act. For example, section 110(a)(2)(H)(i) of the Act provides that SIPs are to provide for revisions ''from time to time as may be necessary to take account of revisions of such national primary or secondary ambient air quality standard * * * .'' Section 107(d)(1)(A) of the Act provides a process for designating areas as attainment, nonattainment, or unclassifiable ''after promulgation of a new or revised standard for any pollutant under section 109 * * * .'' Section 172(e) of the Act addresses modifications of national primary ambient air quality standards. Finally, section 172(a)(1) of the Act expressly contemplates that EPA may revise a standard in effect at the time of enactment of the 1990 Clean Air Act Amendments. Section 172(a)(1)(A) of the Act provides EPA with authority to classify nonattainment areas on or after the designation of an area as nonattainment with respect to ''any revised standard, including a revision of any standard in effect on the date of the enactment of the Clean Air Act Amendments of 1990.'' Plainly, Congress had no intention of prohibiting EPA from revising any of the ambient standards in effect at the time of the enactment of the 1990 amendments.

Third, the provisions of subpart 4 of Part D of Title I of the Act do not support the contention that they somehow preclude EPA from exercising its authority to adopt a revised PM NAAQS based on a metric other than PM_{10}. The fact that Congress laid out an implementation program for the PM standard existing at the time of the 1990 amendments in no way suggests that Congress intended to preclude EPA from exercising the authority it provided EPA to revise the NAAQS when the health data on which EPA bases such decisions warranted a change in the standard.

The fact that Congress drafted subpart 4 of Part D of Title I of the Act in 1990 to specify the implementation regime for the PM standard then in effect, a PM_{10} standard, in terms that explicitly refer to PM_{10} in no way suggests that Congress meant to preclude EPA from adopting a PM standard based on another metric if scientific information supported such a change. Obviously, PM_{10} was the standard in existence in 1990 and Congress drafted subpart 4 of Part D of Title I of the Act, the purpose of which was to delineate an implementation regime for that standard, in terms of that standard. There is simply no language in subpart 4 of Part D of Title I of the Act that limits EPA's ability to establish a different PM standard if such a standard were warranted under section 109 of the Act or indicates any implicit intent on the part of Congress to limit EPA's authority under section 109 of the Act in such a way. Subpart 4 of Part D of Title I of the Act simply does not speak to the question of whether EPA may establish a PM standard based on a different metric. In addition, section 107(d)(4) of the Act, the only provision outside of subpart 4 of Part D of Title I of the Act invoked as a basis for the view that the Act prohibits EPA from adopting a $PM_{2.5}$ standard, does not support that view. That provision simply preserved pre-existing designations for ''total suspended particulates,'' the PM metric utilized prior to PM_{10}, for certain purposes. It provides no suggestion that Congress intended to prohibit EPA from adopting

a metric other than PM_{10}. Indeed, if anything, it indicates that Congress was fully aware that EPA had previously changed the PM metric used in the PM NAAQS and confirms the view that Congress would have explicitly barred EPA from changing the metric had it intended to do so.

Finally, for the reasons stated in this unit, EPA's analysis of its ability to implement a $PM_{2.5}$ standard under the provisions of subpart 1 of Part D of Title I does not support the view that Congress prohibited EPA from promulgating such a standard. Congress clearly specified an approach to the implementation of the PM_{10} standard in the provisions of subpart 4 of Part D of Title I of the Act. The EPA believes that the clear and express linkage of that approach to the PM_{10} standard indicates that a different PM standard should be implemented under the general principles of subpart 1 of Part D of Title I of the Act. That Congress directed specifically how EPA and the States should implement the PM_{10} standard does not carry with it the implication that Congress intended to prohibit EPA from exercising its otherwise clear and express authority to adopt a PM standard based on a different metric in order to carry out one of its fundamental missions, the establishment of ambient air quality standards to protect public health with an adequate margin of safety. It is entirely reasonable and logical for Congress to, on the one hand, specify an implementation regime for the PM standard in effect at the time of enactment of the 1990 amendments, but, on the other hand, leave EPA free to exercise the authority provided it by Congress in section 109 of the Act to adopt a new or revised standard when EPA determined that such a standard was needed to protect public health with an adequate margin of safety. Congress explicitly required EPA to review and revise as appropriate the NAAQS every five years. If Congress did not intend for EPA to revise the NAAQS when warranted, it would not have required EPA to review and revise them. If Congress had intended to prohibit EPA from exercising such a fundamental authority it would have clearly specified, as it did in other instances, that EPA could not do so.

V. Revisions to 40 CFR Part 50, Appendix K—Intrepretation of the PM NAAQS

Because the revocation of the existing PM_{10} standards will become effective at a later date (as discussed in Unit VII. of this preamble), EPA is retaining 40 CFR part 50, Appendix K, although it is being published today in revised format to conform with the format of the other appendices in this part. A new Appendix N to 40 CFR part 50 explains the computations necessary for determining when the primary and secondary $PM_{2.5}$ and PM_{10} standards being adopted today are met. The discussion in this unit sometimes refers to the contents of the new Appendix N as revisions to Appendix K, so as to highlight how the new Appendix N differs from the current Appendix K.

Key elements of the new 40 CFR part 50, Appendix N, particularly as they differ from those of Appendix K, are outlined in this unit.

A. $PM_{2.5}$ Computations and Data Handling Conventions

As discussed in Unit II.E. of this preamble, the form of the annual $PM_{2.5}$ standard is a spatially averaged annual mean averaged over 3 years, and the form of the 24-hour $PM_{2.5}$ standard is a 98^{th} percentile concentration averaged over 3 years.

With regard to the annual $PM_{2.5}$ standard, the EPA proposed a form expressed as the annual arithmetic mean, averaged over 3 years and spatially averaged over all designated monitoring sites to represent population exposures. As discussed in Unit II.E.1. of this preamble, the form of the annual $PM_{2.5}$ standard has been clarified to make explicit that implementing agencies have the flexibility to base comparison of the standard level with measured values from either a single community-oriented site or an average of measured values from such monitors within the constraints enumerated in 40 CFR part 58. The new Appendix N of 40 CFR part 50 reflects this clarification. The spatial average, if used, is to be carried out using data from monitoring sites designated in a State PM Monitoring Network Description in accordance with the provisions of 40 CFR part 58.

Also, the EPA proposed that, for spatial averaging, the requirements for 3 years of data for comparison with the standard be fulfilled by the spatial averaging network as a whole, not by individual monitors within the network. The EPA received comments regarding the application of the 75 percent data completeness requirement to spatial averaging. The commenters stated that the inclusion or exclusion of a site not meeting the data completeness requirements from a spatial average, based on the level of the single site average, would bias the spatial average for that year. The EPA has responded to the comment by demonstrating in Example 1 in 40 CFR part 50, Appendix N the application of the data completeness criterion that is consistent with a spatially averaged network. Specifically, the application of the data completeness requirement has been altered in the example if a particular site has quarters in a year that do not meet the minimum data completeness requirement. Instead of comparing a site's annual average to the level of the standard to decide whether or not to keep the site in the calculations, the annual average for all the sites (the spatial average) is compared to the level of the standard. If the spatial average is above the level of the standard, the site is kept in the calculations. If it is below, the site is omitted from the calculations.

The EPA also proposed that averaging over calendar quarters be retained for the annual average form of the standard. Although several commenters stated that the step of calculating quarterly averages to obtain the annual average was unnecessary, the EPA maintains that quarterly averages are important to ensure representative sampling in areas with extreme seasonal variation.

Regarding the 75 percent data completeness requirement, the proposal stated that a given year meets data completeness requirements when at least 75 percent of the scheduled sampling days for each quarter have valid data, and high values measured in incomplete quarters shall not be ignored but shall be included if their value causes the annual calculation to be above the level of the standard. Some commenters felt that this treatment was unfair in that measured data below the standard in incomplete quarters are not retained. In addition, the commenters felt that this could create a bias where a single sample could inflate an annual average to a level above the standard. The EPA agrees and has incorporated in 40 CFR part 50, Appendix N the following provisions.

(1) A statement has been added that less than complete data may be used in certain cases subject to the approval of the appropriate Regional Administrator in accordance with EPA guidance for dealing with less than complete data. This statement was considered necessary for those situations where measured data and air quality analyses would indicate that the area met or did not meet the standard although it did not exactly meet the data completeness requirements.

(2) A provision has been added that a minimal amount of data is needed before the requirement to retain high values in an incomplete quarter comes into effect for the annual standards. Sites with at least 11 samples but less than 75 percent data completeness in a quarter will have to include high values

if they result in calculated values which are above the level of the standard. This provision is based upon the change in sampling frequency set forth in the revisions to 40 CFR part 58 which effectively doubles the minimum sampling frequency from 1-in-6 day sampling to 1-in-3 day sampling. The data completeness requirement for the annual form of the standard under the original 1-in-6 day sampling schedule is equivalent to a minimum of 37.5 percent under the new sampling schedule of 1-in-3 days. This is equivalent to a minimum of 11 samples in each quarter. Therefore, a minimum of 11 samples in a quarter should be sufficient for an annual average above the level of the standard to be used under the new sampling schedule.

(3) In sharp contrast, this minimum requirement was considered unnecessary for the 24-hour form of the standard when the 98th percentile is above the level of the standard. That is, for a site with a 98th percentile above the level of the standard that does not meet the 75 percent data completeness requirement, the 98th percentile would be equivalent to the maximum or second maximum daily concentration in that year. While adding more data samples up to the minimum data completeness requirement of 75 percent could help to ensure that the second maximum value (rather than the maximum value) corresponds to the 98th percentile, this difference is not considered significant enough to require some minimal number of data samples when dealing with the form of the 24-hour standard.

With regard to the 24-hour $PM_{2.5}$ standard, the proposed revision to 40 CFR part 50, Appendix K defined the 98th percentile as the daily value out of a year of monitoring data below which 98 percent of all values in the group fall. The calculation of the percentile form has been revised to reflect general comments that the form of the standard and its calculation should be simplified. The EPA maintains that the revised calculation is consistent with the definition of the percentile being that number below which a certain percent of the data fall.

Regarding the expression of the annual standard to the nearest 0.1 μg/m^3 and the 24-hour standard to the nearest 1 μg/m^3, virtually no commenters disagreed with the EPA's proposed approach. The few that did, however, took issue with the overall stringency of the standards, not the rationale discussed in the proposal. The EPA maintains its position that instrument sensitivity and the number of measured values used in calculating the values to be compared to the standard, as discussed at length in the proposal, point to keeping the expressions of the standards stated in this unit.

B. PM_{10} Computations and Data Handling Conventions

As discussed in Unit II.G. of this preamble, the EPA proposed retaining the current annual arithmetic mean, averaged over 3 years, as the form of the annual PM_{10} standard, and changing the form of the 24-hour PM_{10} standard to a 98th percentile value form, averaged over 3 years. As discussed in Unit II.G. of this preamble, the form of the daily PM_{10} standard has been revised to a 99th percentile instead of the 98th percentile, and the related calculations have been revised accordingly. The same revision described above in Unit V.A. of this preamble to simplify the formula used to calculate the percentile form of the 24-hour $PM_{2.5}$ standard also applies to the PM_{10} 99th percentile calculation.

The revisions made to the annual and 24-hour $PM_{2.5}$ standards regarding the 75 percent data completeness requirement also apply to the annual and 24-hour PM_{10} standards. Appendix N of 40 CFR part 50 reflects this change.

As with the $PM_{2.5}$ standards, the EPA maintains its position that instrument sensitivity and the number of measured values used in calculating the values to be compared to the standard, as discussed in detail in the proposal, point to keeping the expressions of the standards to the nearest 1 μg/m^3 for the annual standard and to the nearest 10 μg/m^3 for the 24-hour standard.

C. Changes That Apply to Both $PM_{2.5}$ and PM_{10} Computations

In the proposal, the EPA stated that revisions to 40 CFR part 50, Appendix K would not address the treatment of exceptional events data, which are considered part of the standards implementation process. Since several commenters mentioned the handling of these events in conjunction with the proposed revisions to Appendix K, the EPA has addressed this concern in Appendix N of 40 CFR part 50, which states that whether to exclude, retain, or make adjustments to data affected by uncontrollable or natural events is subject to the approval of the appropriate Regional Administrator.

Comments were also received expressing the desire of some areas to conduct seasonal sampling, reducing the frequency of monitoring during a period of expected low concentrations to save resources. The proposed revision to 40 CFR part 50, Appendix K did not prohibit this course of action, and referred matters of sampling frequency to 40 CFR 58.13. For clarification, 40 CFR part 50, Appendix N adds that exceptions to specified sampling frequencies, such as a reduced frequency during a season of expected low concentrations, shall be subject to the approval of the appropriate Regional Administrator.

VI. Reference Methods for the Determination of Particulate Matter as PM_{10} and $PM_{2.5}$ in the Atmosphere

A. Revisions to 40 CFR Part 50, Appendix J—Reference Method for PM_{10}

Because the revocation of the existing PM_{10} standards will become effective at a later date (as discussed in Unit VII. of this preamble), EPA is retaining Appendix J in its current form. A new Appendix M to 40 CFR part 50 establishes the reference method for measuring PM_{10} in the ambient air for the revised PM_{10} standards. The discussion in this unit sometimes refers to the contents of the new Appendix M as revisions to Appendix J, so as to highlight how the new Appendix M differs from the current Appendix J. As discussed below, the only revision to the Reference Method for PM_{10} relates to the calculation of the volume of air sampled.

During the course of this standards review, EPA has received a number of comments regarding the appropriateness of the current practice of adjusting measured PM_{10} concentrations to reflect standard conditions of temperature and pressure (25° C and 760 mm Hg, respectively), as required by 40 CFR part 50, Appendix J. The practice was originally adopted to provide a standard basis for comparing all pollutants measured in terms of mass per unit volume (e.g., μg/m^3). As EPA has reviewed the ambient standards for gaseous pollutants, however, technical changes have been made to express them on a pollutant volume/air volume basis (i.e., ppm) that is insensitive to differences in altitude and temperature. Such an approach is not applicable to particulate pollutants. The question arises whether continuing the past practice of making temperature and pressure adjustments for PM is appropriate or necessary.

Information in the Criteria Document on the health and welfare effects of PM provides no clear basis for making such adjustments. Recent health effects studies have been conducted in cool and warm climates, and in cities at high altitude, e.g., Denver, as well as near sea level, e.g., Philadelphia (U.S. EPA, 1996a). These studies provide no evidence that risk associated with PM exposures is affected by variations in

altitude. Accordingly, any effect that would be accounted for by temperature and pressure adjustments would be below the detection limits of epidemiological studies. While extremes of altitude might be expected to increase the delivered dose of PM in those not acclimatized to such locations, the dosimetric studies summarized in the Criteria Document provide no clear support for any quantitative adjustment to standard conditions. With respect to welfare effects, visibility is directly related to the actual mass of fine particles in the atmosphere. Adjustment of PM concentrations collected at higher altitudes to standard conditions would therefore lead to an overstatement of the effect of PM on visibility in such locations. Similarly, there is no evidence in the Criteria Document suggesting that effects on materials damage and soiling are dependent on altitude.

Based on this assessment, EPA proposed to delete the requirement to adjust PM_{10} concentrations to standard conditions of temperature and pressure from 40 CFR part 50, Appendix J for the revised standards and to make corresponding revisions in 40 CFR 50.3. Comments received on this issue were divided. A number of commentors supported EPA's proposal for the reasons set forth above. A few States opposed the change because the lack of adjustment for very cold temperature in areas near sea level could make the standard more stringent. Some commentors were concerned that the proposed change would relax protection afforded for areas at high altitude. A few commentors expressed concern that ''sojourners'' who visit high altitude area would have higher ventilation rates and receive reduced protection as compared to local residents whose ventilation patterns were more adapted to these conditions.

The EPA does not believe that the localized comparisons regarding increased or decreased stringency of standards relative to the proposed change are an appropriate rationale for keeping the current adjustment for temperature and pressure. The issue is whether the available scientific evidence on the health and welfare effects of PM provides a basis for continuing with the traditional adjustments. The comments with respect to sojourners at altitude are relevant, but this issue was considered in reaching the proposed decision. Furthermore, commentors provided neither laboratory nor epidemiologic evidence that would support their theoretical concerns regarding increased annual or 24-hour PM effects at altitudes typical of mountainous urban areas in the United States.

Based on its assessment of the available evidence and public comments, EPA concludes that a continuation of the practice of adjusting PM_{10} concentrations to standard conditions of temperature and pressure is not warranted or appropriate. Accordingly, this requirement is not included in 40 CFR part 50, Appendix M and corresponding revisions are made in 40 CFR 50.3. In addition, EPA is also incorporating the proposed minor modifications to 40 CFR part 50, Appendix J in Appendix M.

B. 40 CFR Part 50, Appendix L - New Reference Method for $PM_{2.5}$

1. *Introduction.* A new reference method for the measurement of fine particles (as $PM_{2.5}$) in the ambient air has been developed for the primary purpose of determining attainment of the new $PM_{2.5}$ standards. The method is described in the new 40 CFR part 50, Appendix L, and joins the other reference methods (or measurement principles) specified for other criteria pollutants in other appendices to 40 CFR part 50.

In developing the proposed new reference method for $PM_{2.5}$, EPA staff consulted with a number of individuals and groups in the monitoring community, including instrument manufacturers, academics, consultants, and experts in State and local agencies. The approach and key specifications were submitted to the CASAC Technical Subcommittee for Fine Particle Monitoring, which held a public meeting to discuss the proposed new reference method for $PM_{2.5}$ and related monitoring issues on March 1, 1996. Comments on the proposed method were provided orally and in writing by interested parties. The Technical Subcommittee indicated their overall satisfaction with the method in a letter (Price, 1996) forwarded by CASAC to the Administrator.

On December 13, 1996, EPA proposed the new 40 CFR part 50, Appendix L at 61 FR 65676 for public comment. The proposal described in detail the approach taken and the design specifications and performance requirements for the new $PM_{2.5}$ sampler. On January 14, 1997, EPA held a public hearing on the proposed new 40 CFR part 50, Appendix L and associated 40 CFR parts 53 and 58 requirements.

2. *Basic reference method approach.* In addition to the primary purpose of the new $PM_{2.5}$ reference method (determining attainment of the standards), EPA considered a variety of possible secondary goals and objectives that the $PM_{2.5}$ reference method might also fulfill. Subsequently, various alternative $PM_{2.5}$ measurement techniques were evaluated. From this analysis, EPA proposed to base its $PM_{2.5}$ reference method on a conventional type sampler that collects 24-hour integrated $PM_{2.5}$ samples on a 47 mm Teflon filter that is subsequently moisture and temperature conditioned and analyzed gravimetrically. The sampler is a low volume sampler that operates at a flow rate of 1 cubic meter per hour, for a total sample volume of 24 m^3 for the specified 24-hour sample collection period. The sampler is easy to operate, operates over a wide range of ambient conditions, produces a measurement that is comparable to large sets of previously collected PM data in existing databases, and provides a physical sample that can be further analyzed for chemical composition.

3. *Public comments and responses*—

a. *Sampler design.* The EPA received many general comments concerning the proposed sampler design. Commenters suggested the use of a different indicator, use of a different size cut, inclusion of additional constituents (e.g., acid aerosols, carbon, metals, and semi-volatiles), and/or use of a multi-filter method. Early in the development process, design decisions were based on public input and the advice of CASAC on these and other basic design issues. Other factors affecting the basic design of the method were the need for historical continuity, high measurement precision, and simplicity of operation, all in response to current national monitoring objectives and available resources. In selecting the basic measurement approach, substantial weight was given to maintaining comparability to $PM_{2.5}$ samplers, such as the ''dichotomous sampler,'' that were widely used to obtain the data upon which the new standards are based. Given this objective, EPA concludes that the conventional PM measurement approach is appropriate and will provide $PM_{2.5}$ measurements that are comparable to the air quality data used in the health studies that provide the basis for the $PM_{2.5}$ standards.

Although the sampler is conventional in configuration, its design is much more sophisticated than that of previous PM samplers. This more sophisticated sampler, together with improved manufacturing and operational quality assurance, is necessary to achieve the more stringent data quality objectives established for $PM_{2.5}$ monitoring data. To meet precision requirements, the critical mechanical components of the inlet, particle size separator, downtube, and upper portion of the filter holder

are specified by design. All other aspects of the sampler are specified by performance-based specifications.

Several commenters felt that the portions of the sampler that were specified by design would stifle further improvements and innovations. Although the EPA specifies methods by performance whenever possible, for the $PM_{2.5}$ reference method, development of adequate performance specifications for inlet aspiration and particle size discrimination would have been a very difficult, costly, lengthy, and problematic process. Moreover, manufacturer testing of proposed inlet and particle size discrimination devices against such performance specifications would require elaborate specialized facilities and would be extremely costly. For these reasons, the EPA believes that specification of these critical components by design is a prudent and very cost-effective way to ensure good inter-manufacturer and intra-manufacturer precision of the $PM_{2.5}$ measurements. Therefore, these components are specified by design, and other aspects of the sampler are specified by performance, as proposed. Innovations and improved samplers or measurement methods are encouraged and provided for as Class II and III equivalent methods (see 40 CFR part 53).

b. *Inlet and impactor design.* Several commenters addressed the inlet design, noting that the inlet could allow entrance of precipitation and possibly insects. In fact, the inlet selected for the sampler has been used effectively for many years to obtain many of the $PM_{2.5}$ measurements that formed the basis of the epidemiological studies. While EPA acknowledges that there have been some reports of intrusion of precipitation, the Agency believes the problem is relatively minor. Nevertheless, a modification of the inlet has been developed to further reduce the possibility of precipitation (and possibly small insects) reaching the sample filter to damage the $PM_{2.5}$ sample. Extensive wind tunnel tests have shown no significant compromise in the $PM_{2.5}$ aspiration performance of the modified inlet.

In addition, a new provision has been added, in 40 CFR part 50, Appendix L, section 7.3.8, to require that the sampling air entrance of the inlet be at a height of 2 ± 0.2 meters above the supporting surface to help ensure homogeneous air samples when collocated samplers of different types are operated simultaneously.

Other commenters addressed the sharpness of the size cut and how it is obtained, e.g., whether more than two stages should be used and what size cut should be used for each stage. These aspects were carefully considered in selecting the sampler configuration. The selection by EPA of the previously used PM_{10} inlet established the size cut for the first stage, and the second stage was designed to be simple, reliable, and low in cost for user agencies. In EPA's estimation, the advantages of this configuration outweigh any modest advantage that might have been gained by designing a new inlet/separation configuration that would further refine the cut points at each of two (or more) stages.

A few commenters questioned whether the inlet was wind speed dependent at high wind speeds. The selected inlet has been shown to perform well up to 24 km/hr with 10 µm aerosols and is expected to perform well at higher speeds with 2.5 µm aerosols. The EPA again determined that the advantages of using the selected inlet outweighed the possible minor improvement in wind-speed characteristics that might have been obtained by a newly-designed inlet.

Some commenters felt that other types of particle discrimination techniques such as cyclones and virtual impactors, should be allowed. Again, these alternatives were evaluated previously and the specified inlet and impactor were determined to best meet the various objectives of the sampler. However, EPA has provided for considerations of other particle size selection techniques or devices for approval if incorporated into candidate equivalent methods for $PM_{2.5}$.

Several commenters addressed the impactor design, noting that the impactor should be changed to sharpen the size-cut characteristic, to address concerns regarding possible contamination and/or performance loss due to impactor oil, and to improve ease of access to service. To address the first concern, the initial prototype impactor has been modified slightly to sharpen its size-cut. The current impactor is designed to lower cost and to optimize cut sharpness, loading capacity, manufacturing simplicity, manufacturing quality control, serviceability, and reliability. A report containing the penetration efficiency of the impactor is available in Docket No. A-95-54. With regard to impactor oil concerns, the impactor oil selected has a very low vapor pressure, and testing has indicated no contamination of the sample filters with impactor oil. The EPA believes that the impactor design is as accessible as possible, given the design objectives. Some flexibility may be allowed for manufacturers to develop improved closure devices or other external modifications. Proper maintenance will, of course, be very important and will be stressed in the associated operator instruction manuals and in other training and guidance materials. The EPA has been performing field and laboratory tests that will provide detailed guidance for all necessary preventive maintenance. Proper installation procedures for the oil and the impactor filter, as well as all other maintenance requirements, will be available in the quality assurance procedures and guidance contained in the new section 2.12 of Appendix L to be added to EPA's Quality Assurance Handbook for Air Pollution Measurement Systems (EPA/600/R-94/038b).

c. *Anodized aluminum surface.* All internal surfaces exposed to sample air prior to the filter are required to be anodized aluminum as stated in 40 CFR part 50, Appendix L, section 7.3.7. A few commenters expressed concern that the anodized aluminum surfaces in high volume PM_{10} samplers have shown substantial pitting, particularly in the venturi flow control device. The anodized aluminum surfaces are required in the $PM_{2.5}$ sampler to maintain comparability to previously used samplers. The EPA believes that the much lower flow rate in the $PM_{2.5}$ sampler will greatly reduce the pitting tendency, and the active flow control in the $PM_{2.5}$ sampler is not dependent on the physical dimensions of a critical orifice as it is in a venturi flow control device.

d. *Filter for $PM_{2.5}$ sample collection.* The proposed reference method called for the sample to be collected on a 47 mm Teflon filter. Many of the comments received on the measurement method concerned the proposed filter medium and its performance. Commenters expressed concerns with the use of Teflon filters and with the selection of a single-filter method. Several commenters recommended that alternative filter media be allowed, in most cases to support speciation and/or to allow the capture of all PM components. Other comments noted potential advantages of other media in operating characteristics or chemistry requirements. Operational concerns expressed about Teflon filters included tearing, possible loss of integrity, and high cost. Other concerns were that Teflon is generally not conducive to carbon analysis, and that Teflon filters may not hold deposited PM. Many commenters recommended use of a multi-filter sampler to support chemical speciation in addition to compliance determination.

To address some of these general concerns about the performance of the specified filter material, some minor refinements to the filter specifications concerning the filter diameter and the filter support ring have been made to ensure proper performance of the filter in the specified filter holder. Additional clarifications have been made to the maximum moisture pickup and the filter weight stability requirements. Although Teflon may preclude certain chemical analyses (e.g., elemental and organic carbon), the EPA believes that Teflon filter material is the best overall choice to meet the objectives of compliance monitoring and to provide good measurement precision. Other filter media are likely to provide reduced gravimetric precision and preclude more types of subsequent chemical analysis. Additional or alternative samplers or filter types can be considered as candidate equivalent methods under 40 CFR part 53 and can be used for non-compliance monitoring, where necessary.

Compliance monitoring based on mass concentration of $PM_{2.5}$ is the primary objective of the reference method. Multi-filter capability would have substantially increased the cost and complexity of the sampler. However, multi-filter samplers can be considered as candidate equivalent methods. In addition, multi-filter samplers can be used as special purpose monitors (SPMs) to perform characterization studies, develop control strategies, and conduct other special studies as has been done previously for PM_{10}.

In response to numerous comments received on 40 CFR part 50, Appendix L and on the provisions of 40 CFR part 58 regarding the need for chemical speciation, the EPA is assigning a high priority to a chemical speciation trends network through section 105 of the Act grant allocation program and will issue guidance describing the monitoring methods and scenarios under which speciation should be performed. The program will incorporate additional $PM_{2.5}$ samplers that allow for the simultaneous collection of aerosols on multiple filter media.

The associated requirement for archiving filters has been removed from 40 CFR part 50, Appendix L, section 10.17 and relocated to 40 CFR part 58, Appendix A. This change has been made because this is a supplemental monitoring requirement and not an integral part of the reference method for determining compliance with the $PM_{2.5}$ NAAQS.

Provisions of 40 CFR part 50, Appendix L have been clarified to apply not only to a single-sample sampler, but also to a sequential-sample sampler, provided that all specifications are met and no deviations, modifications, or exceptions are made to the inlet, downtube, impactor, or the upper portion of the filter holder. Samplers that have minor changes or modifications in these components, have changes that alter the aerosol's flow path, or contain other significant deviations will be required to meet the requirements of Class I equivalent methods, in the amendments to 40 CFR part 53. Further, a provision has been added to require that sequential sample filters stored in a sequential sampler be adequately covered and protected from contamination during storage periods in the sampler.

A few commenters expressed concern about who must carry out filter tests to determine if they meet the filter specifications. In response, the filter specifications have been clarified to indicate that filter manufacturers should generally carry out most or all of the filter performance tests in order to certify that their filters meet the filter specifications for the $PM_{2.5}$ reference method. In addition, EPA conducts acceptance tests on filters procured for NAMS/SLAMS networks prior to distribution to State and local agencies.

Some commenters requested additional information on the requirement that an ID number be attached to each filter. Preliminary information indicates that it is not practical at this time for either filter manufacturers or users to print an ID number directly on the filter. However, EPA is continuing to pursue this goal. In the meantime, alternative means, such as attaching an appropriate ID number to the filter's storage container, will be necessary. Additional details and possible alternative filter identification methods will be provided in new section 2.12 of the Quality Assurance Handbook for Air Pollution Measurement Systems.

e. *Filter handling/weighing/conditioning requirements.* Many commenters felt that the filter handling requirements for collected $PM_{2.5}$ samples were too burdensome. However, handling of the exposed filter between retrieval from the sampler and commencement of the conditioning period is expected to be one of the most significant sources of $PM_{2.5}$ measurement variability. Thus, EPA concludes that specific requirements for this activity are necessary, and this position was supported by several commenters.

Some commenters felt that the samples should be kept cold until analysis to prevent volatile losses. In response to this concern, the restriction on the maximum temperature exposure for collected samples has been reduced from 32 to 25° C, and a recommendation has been added for sampler operators to keep the samples as cool as practical between retrieval from the sampler and delivery to the conditioning environment. Further, the length of time permitted between retrieval of the filter and post-collection weighing is increased from 10 to 30 days, provided that the sample is maintained at 4° C or less between retrieval and the start of the conditioning period. The new section 2.12 of the Quality Assurance Handbook for Air Pollution Measurement Systems will provide guidance and techniques for keeping samples cool during this period and may suggest devices to document maximum temperature exposure of the sample.

Commenters also requested additional specifications and guidance for field blanks. The EPA will provide additional clarification and detailed procedures and guidance regarding field blanks in the new section 2.12 of the Quality Assurance Handbook for Air Pollution Measurement Systems.

Other commenters felt that the filter weighing requirements were too restrictive. Because filter weighing is one of the most significant sources of $PM_{2.5}$ measurement variability, specific requirements and restrictions are deemed necessary. However, in response to some of the concerns expressed, the proposed requirement that both pre- and post-weighings be carried out by the same analyst has been reduced to a non-mandatory recommendation. Detailed recommendations and guidance on filter weighing, based on information obtained in current field tests, will be provided in the new section 2.12 of the Quality Assurance Handbook for Air Pollution Measurement Systems.

Several commenters questioned the filter conditioning requirements, with some requesting a lower humidity range. Since humidity can profoundly affect the weight of the $PM_{2.5}$ on the filter, EPA maintains that filter conditioning requirements need to be tight to control measurement variability and to ensure satisfactory precision. But in response to at least one of the concerns, the filter conditioning humidity requirement has been changed to allow conditioning at a relative humidity within ±5 RH percent of the mean ambient humidity during sampling (down to a minimum of 20 RH percent) for samples collected at average ambient humidities lower than 30

percent. The EPA will provide further details on filter conditioning controls in the new section 2.12 of the Quality Assurance Handbook for Air Pollution Measurement Systems.

f. *Sampler performance requirements.* Several commenters addressed sampler performance requirements, including sampler flow control specifications, filter temperature control, sampler performance under extreme conditions, and data reporting. In response to concerns that various sampler flow control specifications are too tight, EPA contends that good flow control is necessary to maintain uniform sampling, to ensure correct particle size discrimination, and to control measurement variability. Sampler manufacturers have been able to meet the specified flow control requirements, and field studies to date confirm that prototype samplers are able to meet these flow control requirements.

In response to comments about the ambient temperature plus 3° C filter temperature control requirement, EPA believes that fairly tight control of the sample filter temperature is necessary to minimize losses of semi-volatile components over a wide temperature range, and tight temperature control has been strongly recommended by the CASAC. Monitoring of the filter temperature difference from ambient temperature is necessary to verify that the sampler filter temperature control is functioning properly. Testing to date indicates that the proposed 3° C (above ambient temperature) limit is somewhat difficult to meet; however, a 5° C limit can be reasonably met. Therefore, the filter temperature control requirement has been relaxed slightly from 3° C to not more than 5° C above the concurrent ambient temperature. Ambient and filter temperature sensors will require periodic calibration or verification of accuracy. In response to a frequent comment, the method has been clarified to indicate that exceedance of the filter temperature difference limit would not necessarily invalidate the sample.

In response to concerns about the performance of the sampler under extreme weather conditions (e.g., high or low temperatures, low pressures, high winds, high or low humidity, fog, dust storms), the EPA has established sampler specifications that are intended to cover reasonably normal environmental conditions at about 95 percent of expected monitoring sites. Qualification test requirements in 40 CFR part 53 address most, if not all, of these operational requirements. Specification of the sampler performance for sites with extreme environmental conditions would substantially raise the cost of the sampler for other users, most of whom do not require the extra capability. Users requiring operation of samplers under extreme conditions are encouraged to develop supplemental specifications for modified samplers to cover those specific conditions. Sampler manufacturers have indicated a commitment to respond to the need for modified samplers for such extreme conditions.

Although concerns were expressed that the amount of data required to be reported from each sampler is excessive, EPA stresses that only a portion of the data collected by the sampler needs to be reported to AIRS. These limited data reporting requirements (i.e., ambient and filter temperature, barometric pressure, sample volume, variation in sample run flow rate) are important to establish or verify the reliability and confidence of the $PM_{2.5}$ measurements and to aid in utilization of those data. The substantial amount of additional data generated by the sampler are of use to the site operator to provide confirmation of a given sample's validity, and to aid in troubleshooting should outlier measurements appear in the monitoring data. A variety of current electronic devices and systems may be used to acquire and handle the data, and these devices can easily accommodate the amount of data required to be reported, as well as the additional, optional data. Printers, modem connections, and alternative data output connections or devices are not precluded.

4. *Additional changes.* Additional clarifying changes have also been made throughout 40 CFR part 50, Appendix L, based on comments received or recently obtained field test information. In 40 CFR part 50, Appendix L, section 3.1, the lower concentration of the method has been revised from 1 to 2 $\mu g/m^3$, based on the results of field blanks associated with available field test data. In 40 CFR part 50, Appendix L, section 3.3, the sample period specification has been augmented to clarify that a measured $PM_{2.5}$ concentration for a sample period less than 23 hours that is greater than the NAAQS level(s) is to be considered a valid measurement for comparison to the NAAQS, even though not valid for other purposes. Sections 4 (Accuracy) and 5 (Precision) have been revised to properly reflect associated changes to the data quality and method performance assessment requirements set forth in 40 CFR part 58, Appendix A.

A provision has been added in 40 CFR part 50, Appendix L, section 7.4.17 to require sampler manufacturers to make available computer software to input sampler output data and translate the data into a standard spreadsheet format (since no specific format is specified for output of the sample data acquired by the sampler).

The requirements for the sampler to display current flow rate, temperature, filter temperature, and barometric pressure readings have been changed to require updating of these readings at least every 30 seconds. This change is based on operational experience of prototype samplers in 40 CFR part 50, Appendix L, section 7.4.5.1, and will make it easier for the operators to perform status checks and calibrations. In 40 CFR part 50, Appendix L, section 7.4.8.1, the requirements for the ambient temperature sensor have been changed to specify an external sensor with a passive sun shield, to provide better uniformity in the ambient temperature measurements among different types of reference method samplers. The reference method has also been clarified to indicate that $PM_{2.5}$ samples for which the sampler reported an out-of-specification (FLAG) occurrence during or after the sample period are not necessarily invalid, and that such samples should be reviewed by a quality assurance officer (40 CFR part 50, Appendix L, section 10.12). Finally, a new reference has been added in section 13 of the Act to provide applicable standards for meteorological measurements and measurement systems.

5. *Decision on 40 CFR part 50, Appendix L.* After fully considering the public comments on the proposed new reference method for $PM_{2.5}$, EPA has concluded that the proposed design and performance specifications for the reference sampler, with the modifications discussed in this unit, will achieve the design objectives set forth in the proposal and outlined above. Therefore, EPA is adopting the sampler and other method requirements specified in 40 CFR part 50, Appendix L as the reference method for measuring $PM_{2.5}$ in the ambient air.

Since proposal, a series of field tests have been performed using prototype samplers manufactured in accordance with the proposed design and performance specifications. The results of these field tests confirm that the prototype samplers perform in accordance with design expectations. Operational experience gained through these field tests did, however, identify the need for minor modifications as discussed above in this unit. In addition, EPA made other modifications to the proposed design and performance specification in response to public

comment as discussed above. As part of this process, EPA performed laboratory tests to ensure that the modifications achieved the intended objective.

While the results of these field tests and laboratory tests were largely confirmatory in nature and did not indicate a need to alter the basic design and performance specifications, they did identify areas that needed further refinement. Given that these tests were performed, by necessity, during and after the close of the public comment period and because the results were not available for placement in the docket until late in the rulemaking process, EPA is announcing, in a separate **Federal Register** notice being signed today, a supplemental comment period for the limited purpose of taking comments on these field and laboratory test results.

VII. Effective Date of the Revised PM Standards and Applicability of the Current PM_{10} Standards

In summary, the primary and secondary NAAQS for PM have been revised by establishing annual and 24-hour $PM_{2.5}$ standards; and by changing the form of the existing 24-hour PM_{10} standards. The existing PM_{10} annual standards have been retained. Section 50.3 (reference conditions) of 40 CFR part 50 has been revised to remove the adjustment of measured PM_{10} concentrations to standard conditions of temperature and pressure with respect to the revised PM standards. (Although EPA is retaining the current annual PM_{10} standards, the revision of 40 CFR 50.3 potentially may affect the effective stringency of the annual standards.) A new Appendix M has been added to 40 CFR part 50 that reflects the revision of 40 CFR 50.3. A new Appendix N to 40 CFR part 50 has been added to reflect the forms of the $PM_{2.5}$ and revised PM_{10} standards. Finally, a new Appendix L to 40 CFR part 50 has been added that specifies the reference method for measuring $PM_{2.5}$ in the ambient air.

The revised PM NAAQS, the revisions to 40 CFR 50.3, and the new Appendices M, N, and L to 40 CFR part 50 will become effective September 16, 1997. Inherent in the establishment of this revised set of PM standards and related provisions is the revocation of the current set of PM_{10} standards and associated provisions. To provide for an effective transition from the existing PM standards to the revised PM standards —in light of the need to establish $PM_{2.5}$ monitoring networks, designate areas, and develop control strategies for $PM_{2.5}$—the Administrator has determined that the effective date of the revocation of the current set of PM_{10} standards and associated provisions should be delayed so that the existing standards and associated provisions will continue to apply for an interim period. The duration of the interim period would depend on whether the area in question has attained the current PM_{10} standards, as described below in this unit.

First, section 172(e) of the Act provides that, if the Administrator relaxes a national primary ambient air quality standard, she shall, within 12 months after the relaxation, promulgate requirements applicable to all areas that have not attained that standard as of the date of the relaxation. Those requirements shall provide for controls that are not less stringent than the controls applicable to areas designated nonattainment before such relaxation. Although the set of revised PM standards, viewed as a whole, is more stringent than the set of current PM standards, it appears that the shift from the current PM_{10} standards to the revised PM_{10} standards, viewed in and of itself, represents a relaxation of the current PM_{10} standards. As a result, section 172(e) of the Act requires EPA to issue a rule within 12 months to apply implementation requirements no less stringent than the currently applicable requirements for those areas that have not yet attained the current PM_{10} standard(s) by today's promulgation. However, the Act does not specifically provide how to ensure that States with current PM_{10} problems should maintain the necessary public health protection in the interim between promulgation of a relaxed standard and issuance of a rule under section l72(e) of the Act. For that reason, EPA believes that it is both necessary and appropriate to defer the effective date of the revocation of the current PM_{10} standards, for areas that have not attained those standards, until EPA issues the rule called for by section 172(e) of the Act.

Second, since it will take many years for States to identify PM problems under the revised standards and to develop effective means for addressing those problems, EPA believes it is necessary for even those areas that have already attained the current PM_{10} standards (and hence are not subject to the terms of section 172(e) of the Act) to continue their current PM_{10} implementation efforts for the purpose of protecting public health in the transition to implementation of the revised standards.

In order to deal with both of these categories of areas—those that are not attaining the current PM_{10} standards and those that are in attainment of the current PM_{10} standards—EPA is taking a two-pronged approach towards deferral of the effective date of the revocation of the current PM_{10} standards. For those areas that are not attaining the current PM_{10} standards at the time of the promulgation of the revised PM_{10} standards, the current standards will continue to apply until EPA has completed its rulemaking under section 172(e) of the Act to prevent backsliding in those areas. This will assure that no backsliding can occur in the interim period between the promulgation of the revised standards and the completion of the rulemaking under section 172(e) of the Act. For those areas that are attaining the current PM_{10} standards at the time of promulgation of the revised PM_{10} standards, the existing PM_{10} standards will continue to apply until the areas have an approved SIP that includes any control measures that had been adopted and implemented at the State level to meet the current PM_{10} NAAQS and have an approved section 110 SIP for purposes of implementing the revised PM standards. If an area has already received approval of a PM_{10} SIP embodying all of the measures that had been adopted and implemented at the State level, no further Part D submission or approval would be necessary. If an area has already submitted such measures, EPA would need to take action to approve them. Finally, if an area has not yet submitted such measures to EPA for inclusion in the SIP, the area would need to submit them and EPA would need to approve them. This submission and approval would serve to satisfy both the area's remaining subpart D obligations and, in part, its new obligations under section 110(a)(1) of the Act regarding the implementation of the revised PM NAAQS. EPA emphasizes that it is not requiring an approval of a modeled attainment demonstration for the current PM_{10} NAAQS, only an approval of the control measures that had in fact been adopted and implemented and that, therefore, were responsible for the area's attainment of the current PM_{10} standards.

The existing definition of reference conditions and 40 CFR part 50, Appendices J and K will remain in force as long as the current PM_{10} standards apply to an area. Additional policies and guidance for assuring an effective transition will be set forth in future EPA guidance, policies, and/or rules.

VIII. Regulatory and Environmental Impact Analyses

As discussed in Unit IV of this preamble, the Clean Air Act and judicial

decisions make clear that the economic and technological feasibility of attaining ambient standards are not to be considered in setting NAAQS, although such factors may be considered in the development of State plans to implement the standards. Accordingly, although, as described below, a Regulatory Impact Analysis (RIA) has been prepared, neither the RIA nor the associated contractor reports have been considered in issuing this final rule.

A. Executive Order 12866

Under Executive Order 12866, 58 FR 51735 (October 4, 1993), the Agency must determine whether a regulatory action is ''significant'' and, therefore, subject to Office of Management and Budget (OMB) review and other requirements of the Executive Order. The order defines ''significant regulatory action'' as any regulatory action that is likely to result in a rule that may:

(1) Have an annual effect on the economy of $100 million or more or adversely affect in a material way the economy, a sector of the economy, productivity, competition, jobs, the environment, public health or safety, or State, local, or tribal governments or communities.

(2) Create a serious inconsistency or otherwise interfere with an action taken or planned by another Agency.

(3) Materially alter the budgetary impact of entitlements, grants, user fees, or loan programs or the rights and obligations of recipients thereof.

(4) Raise novel legal or policy issues arising out of legal mandates, the President's priorities, or the principles set forth in the Executive Order.

In view of its important policy implications, this action has been judged to be a ''significant regulatory action'' within the meaning of the Executive Order. As a result, under section 6 of the Executive Order, EPA has prepared an RIA, entitled ''Regulatory Impact Analysis for Particulate Matter and Ozone National Ambient Air Quality Standards and Proposed Regional Haze Rule (July 1997).'' This RIA assesses the costs, economic impacts, and benefits associated with potential State implementation strategies for attaining the PM and O_3 NAAQS and the proposed Regional Haze Rule. Changes made in response to OMB suggestions or recommendations will be documented in the public docket and made available for public inspection at EPA's Air and Radiation Docket Information Center (Docket No. A-95-58). The RIA will be publicly available in hard copy by contacting the U.S. Environmental Protection Agency Library at the address under ''Availability of Related Information'' and in electronic form as discussed above in ''Electronic Availability.''

B. Regulatory Flexibility Analysis

The Regulatory Flexibility Act (RFA), 5 U.S.C. 601 *et seq.*, provides that, whenever an agency is required to publish a general notice of rulemaking for a proposal, the agency must prepare an initial regulatory flexibility analysis for the proposal unless the head of the agency certifies that the rule will not, if promulgated, have a significant economic impact on a substantial number of small entities (section 605(b)). The EPA certified the proposed NAAQS rule based on its conclusion that the rule would not establish requirements applicable to small entities and therefore would not have a significant economic impact on small entities within the meaning of the RFA. See 61 FR 65638, 65668 (PM proposal) and 61 FR 65716, 65764 (ozone proposal), both published December 13, 1996. Accordingly, the Agency did not prepare an initial regulatory flexibility analysis for the proposal, but it did conduct a more general analysis of the potential impact on small entities of possible State strategies for implementing any new or revised NAAQS.

At the heart of EPA's certification of the proposed NAAQS rule was the Agency's interpretation of the word ''impact'' as used in the RFA. Is the ''impact'' to be analyzed under the RFA a rule's impact on the small entities that will be subject to the rule's requirements, or the rule's impact on small entities in general, whether or not they will be subject to the rule? In the case of NAAQS rules, the question arises because of the congressionally designed mixture of Federal and State responsibilities in setting and implementing the NAAQS.

As EPA explained in the proposal, NAAQS rules establish air quality standards that States are primarily responsible for meeting. Under section 110 and Part D of Title I of the Act, every State develops a State Implementation Plan (SIP) containing the control measures that will achieve a newly promulgated NAAQS. States have broad discretion in the choice of control measures. As the U.S. Supreme Court noted in *Train* v. *NRDC*, 421 U.S. 60 (1975), 95 S. Ct. 1470:

> [P]rimary [NAAQS] deal with the quality of outdoor air and are fixed on a nationwide basis at a level which the agency determines will protect the public health. It is the attainment and maintenance of these standards which section 110(a)(2)(A) requires that State plans provide. In complying with this requirement, a State's plan must include ''emission limitations'' which are regulations of the composition of substances emitted into the ambient air from such sources as power plants, service stations and the like. They are the specific rules to which operators of pollution sources are subject and which, if enforced, should result in ambient air which meets the national standards.
>
> The Agency is plainly charged by the Act with the responsibility for setting the national ambient air standards. Just as plainly, it is relegated to a secondary role in the process of determining and enforcing the specific, source-by-source emission limitations which are necessary if the national standards are to be met. Under 110(a)(2), the Agency *is required* to approve a State plan which provides for the timely attainment and maintenance of the ambient air standards, and which also satisfies that sections other general requirements. The Act gives the agency no authority to question the wisdom of a state's choices of emission limitations if they are part of a plan which satisfies the standards of 110(a)(2) and the Agency may devise and promulgate a plan of its own only if the State fails to submit an implementation plan which satisfies those standards. Section 110(c).
>
> 421 U.S. 60 at 78–79 (emphasis in original). In short, NAAQS rules themselves do not establish any control requirements applicable to small entities. State rules implementing the NAAQS may establish such requirements and the extent to which they do depends primarily on each State's strategy for meeting the NAAQS.[95]

To determine the proper interpretation of impact under the RFA, EPA considered the RFA's stated purpose, its requirements for regulatory flexibility analyses, its legislative history, the amendments made by the Small Business Regulatory Enforcement Fairness Act of 1996 (SBREFA) (Pub. L. 104–121), and caselaw. The EPA concluded that all of these traditional tools of statutory construction point in one direction—that an agency is required to assess the impact of a rule on the small entities that will be subject to the rule's requirements, because the purpose of a regulatory flexibility analysis is to consider ways of easing or even waiving a rule's requirements as they will apply to small entities, consistent with the statute authorizing

[95] It is worth noting that Federal rules that apply nationally also play a role in reducing emissions governed by NAAQS. For instance, EPA rules under Title II of the Act require reductions in ozone-forming emissions from on and off-road vehicles and the fuels that power them. When EPA issues such rules, it conducts the analysis required under the RFA. For example, EPA performed regulatory flexibility analyses for the reformulated gasoline rule issued under section 211(k) of the Act. See 59 FR 7716, February 16, 1994.

the rule. That purpose cannot be served in the case of the rules like the NAAQS that do not have requirements that apply to small entities.

More specifically, EPA noted that its interpretation of ''impact'' flows from the express purpose of the RFA itself. As the RFA's ''Findings and Purposes'' section (Pub. L. 96–354, section 2) makes clear, Congress enacted the RFA in 1980 out of concern that agencies were writing one-size-fits-all regulations that in fact did not fit the size and resources of small entities. Congress noted that it is generally easier for big businesses to comply with regulations, and that small businesses are therefore at a competitive disadvantage in complying with uniform rules. Congress also noted that small entities' relative contribution to the problem a rule is supposed to solve may not warrant applying the same requirements to large and small entities alike. In the RFA itself, Congress therefore stated:

> It is the purpose of this Act to establish as a principle of regulatory issuance that agencies shall endeavor, consistent with the objectives of the rule and of applicable statutes, to fit regulatory and informational requirements to the scale of the businesses, organizations, and governmental jurisdictions subject to regulation.

(Pub. L. 96–354, section 2(b))

The EPA further noted that the RFA sections governing initial and final regulatory flexibility analyses reflect this statement of purpose. Sections 603 and 604 of the RFA require that initial and final regulatory flexibility analyses identify the types and estimate the numbers of small entities ''to which the proposed will apply'' (sections 603(b)(3) and 604(a)(3) of the RFA). Similarly, they require a description of the ''projected reporting, recordkeeping, and other compliance requirements of the proposal, including an estimate of the classes of small entities which will be subject to the requirement'' (sections 603(b)(4) and 604(a)(4)). At the core of the analyses is the requirement that agencies identify and consider ''significant regulatory alternatives'' that would ''accomplish the stated objectives of applicable statutes and which minimize any significant economic impact of the proposal on small entities'' (sections 603(c) and 604(a)(5)). Among the types of alternatives agencies are to consider are the establishment of different ''compliance or reporting requirements or timetables'' for small entities and the exemption of small entities ''from coverage of the rule, or any part'' of the rule (section 603(c)(1) and (4) of the RFA). The RFA thus makes clear that regulatory flexibility analyses are to focus on how to minimize rule requirements on small entities.

As EPA further explained, since regulatory flexibility analyses are not required for a rule that will not have a ''significant economic impact on a substantial number of small entities'', it makes sense to interpret ''impact'' in light of the requirements for such analyses. Regulatory flexibility analyses, as described in this unit, are to consider how a rule will apply to small entities and how its requirements may be minimized with respect to small entities. In this context, ''impact'' is appropriately interpreted to mean the impact of a rule on the small entities subject to the rule's requirements.

The Agency cited two Federal court cases in support of its interpretation. In *Mid-Tex Elec. Co-op* v. *FERC*, 773 F.2d 327, 342 (D.C. Cir. 1985), petitioners claimed that the RFA required an agency to analyze the effects of a rule on small entities that were not regulated by the rule but might be indirectly impacted by it. Petitioners noted that the Small Business Administration (SBA) also interpreted the RFA to require analysis of a rule's impact on small entities not regulated by the rule, and argued that the court should defer to the SBA's position in light of its compliance monitoring role under the RFA. After reviewing the RFA's ''Findings and Purposes'' section, its legislative history, and its requirements for regulatory flexibility analyses, the Mid-Tex court rejected petitioners' interpretation. As the court explained:

> The problem Congress stated it discerned was the high cost to small entities of compliance with uniform regulations, and the remedy Congress fashioned—careful consideration of those costs in regulatory flexibility analyses—is accordingly limited to small entities subject to the proposed regulation * * *. [W]e conclude that an agency may properly certify that no regulatory flexibility analysis is necessary when it determines that the rule will not have a significant economic impact on a substantial number of small entities that are subject to the requirements of the rule.

Id. at 342. Notably, Congress let this interpretation stand when it recently amended the RFA in enacting SBREFA.

The EPA also cited a recent case affirming the Mid-Tex court's interpretation. In *United Distribution Companies* v. *FERC*, 88 F.3d 1105, 1170 (D.C. Cir. 1996), the court noted that the Mid-Tex court:

> * * * conducted an extensive analysis of RFA provisions governing when a regulatory flexibility analysis is required and concluded that no analysis is necessary when an agency determines ''that the rule will not have a significant economic impact on a substantial number of small entities *that are subject to the requirements of the rule*''.

Id., citing and quoting Mid-Tex (emphasis added by United Distribution court). The Agency went on to explain that given the Federal/State partnership for attaining healthy air, the proposed NAAQS, if adopted, would not establish any requirements applicable to small entities. Instead, any new or revised standard would establish levels of air quality that States would be primarily responsible for achieving by adopting plans containing specific control measures for that purpose. The proposed NAAQS rule was thus not susceptible to regulatory flexibility analysis as prescribed by the amended RFA. Since it would establish no requirements applicable to small entities, it afforded no opportunity for EPA to fashion for small entities less burdensome compliance or reporting requirements or timetables, or exemptions from all or part of the rule. For these reasons, EPA certified that the proposal ''will not, if promulgated, have a significant economic impact on a substantial number of small entities,'' within the meaning of the RFA. Because EPA was not required to prepare an initial regulatory flexibility analysis for the rule, it was also not required to convene a Small Business Advocacy Review Panel for the rule under section 609(b) of the RFA, as added by SBREFA.

Notwithstanding its certification of the proposal, EPA recognized that the proposed NAAQS, if adopted, would begin a process of State implementation that could eventually lead to small entities having to comply with new or different control measures, depending on the implementation plans developed by the States. EPA also recognized that the Act does not allow EPA to dictate or second-guess how States should exercise their discretion in regulating to attain any new or revised NAAQS. Under those circumstances, EPA concluded that the best way to take account of small entity concerns regarding any new or revised NAAQS was to work with small entity representatives and States to provide information and guidance on how States could address small entity concerns when they write their implementation plans.

In line with this approach, as part of RIA it prepared for the proposed NAAQS, EPA analyzed how hypothetical State plans for implementing the proposal might affect small entities. The analysis was necessarily speculative and limited, since it depended on projections about what States might do several years in the future and did not take into account

any new strategies that might be developed and recommended by the FACA subcommittee formed to help devise potential strategies for implementing a new or revised NAAQS (see discussion of RIA and FACA process in this document). Nevertheless, the analysis provided as much information on potential small entity impacts as was reasonably available at the time of the proposal.

The Agency also took steps to ensure that small entities' voices were heard in the NAAQS rulemaking itself. With Jere Glover, Chief Counsel for Advocacy of the SBA, EPA convened outreach meetings modeled on the SBREFA panel process to solicit and convey small entities' concerns with the proposed NAAQS. Two meetings were held as part of that process, on January 7 and February 28, 1997, with a total attendance of 41 representatives of small businesses, small governments, and small nonprofit organizations. Both meetings were attended by representatives of SBA and OMB, as well as of EPA. The key concerns raised by small entities at those meetings related to the scientific foundation of the proposed NAAQS and the potential cost of implementing it, the same concerns raised by other industry commenters on the proposal. The Agency produced a report on the meetings to ensure that small entity concerns were part of the rulemaking record when EPA made its final decision on the proposal.

In light of States' pivotal role in NAAQS implementation, EPA also undertook a number of additional activities to assist and encourage the States to be sensitive to small entity impacts as they implement any new or revised NAAQS. With the SBA, EPA began an interagency panel process to collect advice and recommendations from small entity representatives on how States could lessen any impacts on small entities. The EPA plans to issue materials in two phases to help States develop their implementation plans. In view of States' discretion in implementing the NAAQS, these materials will mostly take the form of guidance, which is not subject to the RFA's requirement for initial regulatory flexibility analysis. (Under section 603 of the RFA, that requirement applies only to binding rules that are required to undergo notice and comment rulemaking procedures.) But regardless of the form such materials take, EPA is employing panel procedures to ensure that small entities have an opportunity to raise any concerns prior to the materials being issued in draft form.

To supplement the input the Agency receives from the ongoing FACA process (described previously in this document), EPA also added more small entity representatives to the Subcommittee on implementation of any new or revised NAAQS. These representatives have formed a small entity caucus to develop and bring to the Subcommittee a focused approach to small entity issues. These new Subcommittee members are also part of the group in the aforementioned panel process. By means of these various processes, EPA hopes to promote the consideration of small entity concerns and advice throughout the NAAQS implementation process.

In response to the proposal, a number of commenters questioned EPA's decision to certify that the proposed NAAQS will not have a significant impact on a substantial number of small entities. Some commenters disagreed with EPA's view that the proposed NAAQS would not establish regulatory requirements applicable to small entities. These commenters argued that a number of control requirements applicable to small entities would automatically result from promulgation of the proposed NAAQS, such as new reasonable further progress, SIP and Federal Implementation Plan (FIP) requirements. Other commenters stated that it is possible for EPA to assess the impacts of the NAAQS revision on small entities and that, to a limited extent, EPA has already done so. Further, a number of commenters argued that EPA has a legal obligation under the RFA, as amended by SBREFA, to choose a NAAQS alternative that minimizes the impact on small entities. Some commenters questioned EPA's interpretations of the Mid-Tex and United Distribution cases. In addition, other commenters stated that EPA's position regarding the NAAQS and the RFA is inconsistent with its past practice and the legislative history of the RFA. Finally, a few commenters noted that the panel process EPA conducted for the proposed NAAQS did not satisfy the requirements of SBREFA.

EPA disagrees that promulgation of the NAAQS will automatically result in control requirements applicable to small entities that EPA can and must analyze under the RFA. As noted previously in this unit, a NAAQS rule only establishes a standard of air quality that other provisions of the Act call on States (or in case of State inaction, the Federal government) to achieve by adopting implementation plans containing specific control measures for that purpose. Following promulgation of a new or revised NAAQS, section 110 of the Act requires States and EPA to engage in a designation process to determine what areas within each State's borders are attaining or not attaining the NAAQS. Under section 110 and Parts C and D of Title I of the Act, States then conduct a planning process to develop and adopt their SIPS. Depending on an area's designation for the particular NAAQS, these and other Title I provisions of the Act require a State's SIP to contain certain control programs in addition to the control measures that the State decides are also needed to attain and maintain the NAAQS.

The fact that the Act requires SIPs to contain certain control programs under certain circumstances does not mean that EPA either can or must conduct a regulatory flexibility analysis of a rule establishing a NAAQS. Just from the standpoint of feasibility, EPA cannot know which areas will be subject to what mandatory SIP programs until after the designation process is completed. Beyond that, any mandatory SIP programs are still implemented by the States, and States have considerable discretion in how they implement them. For instance, the reasonable further progress requirement under section 172 of the Act leaves States broad discretion to determine the rate of progress and the control measures to achieve that progress.[96] As a result, EPA cannot be certain where and how any mandatory programs will be implemented with respect to small (or large) entities. Much less can EPA know about how States will exercise their discretion to develop additional controls needed to attain and maintain the NAAQS.

Even if EPA could know exactly how any mandatory SIP programs would apply to small entities, the purpose of the RFA is not served by attempting a regulatory flexibility analysis of State implementation of those programs. As explained previously in this unit, the RFA and the caselaw interpreting it clearly establish that the purpose of the RFA is to promote Federal agency efforts to tailor a rule's requirements to the scale of the small entities that will be subject to it. That purpose cannot be served in the case of a NAAQS rule since the rule does not establish requirements applicable to small

[96]The SIP requirements of subpart 4 of Part D of Title I of the Act apply to SIPs for areas designated as not attaining NAAQS for PM_{10}. Those requirements will not apply to SIPs to implement the $PM_{2.5}$ NAAQS. Further, to the extent SIPs for areas in nonattainment with the applicable PM_{10} NAAQS remain subject to subpart 4 requirements, there will be no incremental change in the impact on sources regulated by the States' SIPs pursuant to those requirements as a result of this promulgation.

entities. In promulgating a NAAQS, the only choice before EPA concerns the level of the standard, not its implementation. While mandatory SIP programs may ultimately follow from promulgation of the NAAQS, there is nothing EPA can do in setting the NAAQS to tailor those programs as they apply to small entities. Whether and how the programs will apply in particular nonattainment areas is beyond the scope of the NAAQS rulemaking and, indeed, beyond EPA's reach in any rulemaking to the extent the applicability and terms of the programs are prescribed by statute.[97] Moreover, any mandatory SIP programs are supplemented by discretionary State controls that EPA has no power to tailor under the RFA or the Act (see *Train* v. *NRDC*, quoted previously in this unit).

The commenters' suggestions for minimizing the potential impact of the NAAQS rule on small entities run afoul of both the RFA and the Act. Some suggested that EPA set a less stringent standard (or no standard at all in the case of $PM_{2.5}$) to reduce the chance that small entities would become subject to new or tighter SIP requirements. Others suggested that EPA require States to exempt small entities from new or tighter SIP requirements. However, as explained previously in this document, the RFA neither requires nor authorizes EPA to set a less stringent NAAQS than the applicable Clean Air Act provisions allow in order to reduce potential small entity impacts. Indeed, the RFA provides that any means of providing regulatory flexibility to small entities be consistent with the statute authorizing the rule. Moreover, even if EPA set a less stringent standard, States could still exercise their discretion to obtain any needed emission reductions from small entities. As the Supreme Court in *Train* v. *NRDC* made clear, EPA has no authority to forbid States from obtaining reductions from any particular category of stationary sources, including small entities. See also, *Virginia* v. *EPA*, No. 108 F.3d 1397, 1408 (D.C. Cir. 1997), quoting *Union Electric* v. *EPA*, 427 U.S. 246, 269 (1976) (''section 110 left to the states the power to determine which sources would be burdened by regulations and to what extent'').

EPA's approval of SIPs for the new or revised NAAQS also will not establish new requirements, but will instead simply approve requirements that a State is already imposing. And again, EPA does not have authority to disapprove a State's plan except to the extent that the plan fails to demonstrate attainment and maintenance of the NAAQS as required by Title I of the Clean Air Act. In cases where EPA promulgates a FIP, EPA might establish control requirements applicable to small entities, and in such a circumstance, EPA would conduct the analyses required by the RFA.

Some commenters argued that under the RFA as amended by SBREFA, EPA now has an obligation to choose the alternative that minimizes the impact on small entities when setting the NAAQS. As indicated previously in this unit, EPA disagrees with the commenters' argument for the reasons stated in this document's discussion of the Agency's authority to consider costs and other factors not related to public health in setting and revising primary NAAQS. In a nutshell, both the text and legislative history of the RFA make clear that the RFA does not override the substantive provisions of the statute authorizing the rule, but only requires agencies to identify and consider ways of minimizing the economic impact on small entities subject to the rule in a manner consistent with the authorizing statute.

Some commenters disagreed with EPA's interpretation of the Mid-Tex and United Distribution cases. In particular, these commenters noted that in those cases the relevant regulatory agency, Federal Energy Regulatory Commission (FERC), wholly lacked jurisdiction to regulate the small entities at issue. According to these commenters, EPA does have the ability and jurisdiction to regulate small entities in the case of the NAAQS, and therefore EPA's reliance on Mid-Tex and United Distribution is misplaced.

The commenters' attempt to distinguish the FERC cases from the NAAQS rulemaking wholly overlooks the courts' reasoning, which in fact fully supports EPA's certification of the proposed NAAQS. As described previously in this unit, the Mid-Tex court exhaustively reviewed the relevant sections of the RFA and its legislative history. Its analysis revealed that Congress passed the RFA out of concern with one-size-fits-all regulations and fashioned a remedy limited to regulations that apply to small entities. This principle is fully applicable to the NAAQS, which creates no rule requirements that apply to small entities.

The fact that FERC had no regulatory authority over the small entities indirectly affected by its rules played no essential role in the court's rationale. FERC could (and apparently did in the Mid-Tex rulemaking) estimate the potential indirect impact of its rules on small entities. Presumably, FERC could have also mitigated any indirect impact by changing some aspect of the rule (or else the small entities would have had no incentive to sue the agency). The court nevertheless found it unnecessary for FERC to do either, based on its reading of the RFA as limited to analysis of a rule's impact on the small entities subject to the rule's requirements. In reaching its decision, the court noted that requiring agencies to ''consider every indirect effect that any regulation might have on small businesses * * * is a very broad and ambitious agenda, * * * that Congress is unlikely to have embarked on * * * without airing the matter.'' Mid-Tex, 773 F.d. at 343.

The commenters also overstate EPA's regulatory authority over small entities with respect to the regulation of criteria pollutants. Various provisions of the Clean Air Act authorize EPA to regulate various types of sources at the Federal level to accomplish specified goals. However, EPA's authority to more generally regulate sources, including small entities, in the manner of SIPs is limited to instances of State default of SIP responsibilities. When that occurs, EPA may issue a FIP containing specific control measures, and to the extent a proposed FIP would establish control measures applicable to small entities, EPA would analyze the small entity impact of those measures as required by the RFA. In 1994, for example, EPA prepared an initial regulatory flexibility analysis when it proposed a FIP for Los Angeles. See 59 FR 23264 (May 5, 1994).

As noted previously in this unit, Congress let the Mid-Tex interpretation stand when it recently amended the RFA in enacting SBREFA. If it had disagreed with the court's decision, it would have revised the relevant statutory provisions or otherwise indicated its disagreement when it enacted SBREFA. Instead, Congress actually reinforced the Mid-Tex court's interpretation of the RFA in enacting section 212(a) of SBREFA. That section requires that an agency issue a ''small entity compliance guide'' for ''each rule * * * for which an agency is required to prepare a final regulatory flexibility analysis under section 604'' of the RFA. The guide is ''to assist small entities in complying with the rule'' by ''explain[ing] the actions a small entity is required to take to comply'' with the rule (section 212(a) of SBREFA). Obviously, it makes no sense to prepare a small entity compliance guide for a rule that does not apply to small entities. Thus SBREFA stands as further confirmation that Congress intended the

[97] If and when the Agency issues any rules addressing State implementation of any statutorily required actions, EPA would analyze and address the impact of those rules on small entities as appropriate under the RFA.

RFA to address only rules that establish requirements small entities must meet. Since SBREFA's passage, the United Distribution court has affirmed the Mid-Tex court's interpretation.

Some commenters noted that EPA's informal panel process did not comply with the requirements of SBREFA. The EPA did not convene a SBREFA panel because such a panel is not required for rules like the NAAQS that do not apply to small entities. Under the RFA as amended by SBREFA, since the Agency certified the proposal, it was not required to convene a panel for it. Nevertheless, EPA conducted the voluntary panel process described previously in this unit, as well as other voluntary small business outreach efforts. The process could not comply with the analytical requirements of the RFA for the reasons given in this unit. However, it could and did ensure that EPA heard directly from small entities about the NAAQS proposals.

A few commenters stated that EPA's view of the NAAQS and the RFA is inconsistent with EPA's past positions regarding the RFA and NAAQS revisions. Some commenters also cited the RIA for the proposed NAAQS and noted that this analysis demonstrates EPA's ability to estimate the impact of the NAAQS on small entities, thereby undercutting EPA's argument that it is not able to perform a regulatory flexibility analysis when setting the NAAQS.

Past **Federal Register** documents make clear that the nature of the NAAQS makes a regulatory flexibility analysis inapplicable to NAAQS rulemakings. For instance, in 1984, EPA stated that a ''NAAQS for NO_x by itself has no direct impact on small entities. However, it forces each State to design and implement control strategies for areas not in attainment.'' See 49 FR 6866, 6876 (February 23, 1984); see also, 50 FR 37484, 37499 (September 13, 1985); 50 FR 25532, 25542 (June 19, 1985) (NAAQS for NO_2 do not impact small entities directly). EPA stated again in 1987 that the NAAQS ''themselves do not contain emission limits or other pollution controls. Rather, such controls are contained in state implementation plans.'' See 52 FR 24634, 24654 (July 1, 1987).

EPA has typically performed an analysis to assess, to the extent practicable, the potential impact of retaining or revising the NAAQS on small entities, depending on possible State strategies for implementing the NAAQS. These analyses have provided as much insight into the potential small entity impacts of implementing revised NAAQS as could be provided at the NAAQS rulemaking stage. In some instances, these preliminary analyses were described as ''regulatory flexibility analys[es]'' or as analyses ''pursuant to this [Regulatory Flexibility] Act.'' See, e.g., 52 FR 24634, 24654 (July 1, 1987); 50 FR 37484, 37499 (September 13, 1985).

However, these analyses were based on hypothetical State control strategies, and EPA made the point on various occasions that any conclusions to be drawn from such analyses were speculative, given that the NAAQS themselves do not impose requirements on small entities. Although these past analyses reflected the Agency's best efforts to evaluate potential impacts, they were not regulatory flexibility analyses containing the necessary elements required by the RFA. These analyses, for example, did not describe the reporting, recordkeeping, and other compliance requirements of the proposed NAAQS rules that would apply to small entities, since the NAAQS rules did not apply to small entities. Nor did they determine how the proposed NAAQS rules could be eased or waived for small entities. Such an analysis is not possible in the case of the NAAQS. To the extent EPA labeled these analyses regulatory flexibility analyses in the past, that label was inappropriate. EPA's current practice is to describe such an analysis more accurately as a general analysis of the potential cost impacts on small entities. See, e.g., 61 FR 65638, 65669, 65747 (December 13, 1996) (current O_3 and PM NAAQS proposals).[98] EPA's analytical approach to small entity impacts of the NAAQS has thus remained consistent over time.

One commenter noted that the legislative history of the RFA suggests that the RFA was intended to apply to the NAAQS. As noted previously in this unit, EPA's reading of both the RFA and SBREFA, based on the language of the statute as amended and its legislative histories and applicable caselaw, is that the RFA requirements at issue do not apply to the NAAQS. The legislative history cited by the commenter does not change this conclusion.

In fact, the statement by Senator Culver on which the commenter relies does not indicate that the NAAQS should be subject to regulatory flexibility analyses. Rather, Senator Culver uses the NAAQS as an example of the type of standard that agencies would not change as a result of the RFA. According to Senator Culver, section 606 of the RFA ''succinctly states that this bill does not alter the substantive standard contained in underlying statutes which defines the agency's mandate.'' 126 Cong. Rec. S 21455 (August 6, 1980) daily ed. After citing section 109 of the Act, Senator Culver goes on to describe EPA's bubble policy (which addresses the limits on emissions from a particular facility) as the type of flexible regulation that agencies should consider, once EPA has set a NAAQS. ''The important point for purposes of this discussion is that the 'bubble concept,' a type of flexible regulation, in no manner altered the basic statutory substantive standard of the EPA * * *. No regulatory flexibility analysis alters the substantive standard otherwise applicable by law to agency action.'' *Id.* Thus, contrary to the suggestion of the commenter, Senator Culver's statement actually confirms that the time to consider regulatory flexibility is when regulations applicable to sources are being established, not when a NAAQS itself is being set.

Under section 604 of the RFA, whenever an agency promulgates a final rule under section 553 of the Administrative Procedure Act, after being required by that section or any other law to publish a general notice of proposed rulemaking (NPRM), the agency is required to prepare a final regulatory flexibility analysis. RFA section 605(b) provides, however, that section 603 (re initial regulatory flexibility analyses) and section 604 do not apply if the agency certifies that the rule will not have a significant economic impact on a substantial number of small entities and publishes such certification at the time of publication of the NPRM or at the time of the final rule.

As noted above, EPA certified this final rule at the time of the NPRM. After considering the public comments on the certification, EPA continues to believe that this final rule will not have a significant economic impact on a substantial number of small entities for the reasons explained above and that it

[98] As commenters pointed out, the RIA for the proposed PM NAAQS does state that ''[t]he screening analysis * * * provides enough information for an initial regulatory flexibility analysis (RFA) if such an analysis were to be done.'' That statement was mistaken and was not made in the RIA for the proposed ozone NAAQS. While both RIAs attempted to gauge the potential impact on small entities of State implementation of the proposed NAAQS, neither could or did identify any specific control or information requirements contained in the NAAQS rule that would apply to small entities. Indeed, both RIAs made clear that the impact being analyzed was that of potential State measures to attain the NAAQS, and that such an analysis was inherently speculative and uncertain. Thus, the RIAs actually confirm EPA's statement in the preambles for the proposed NAAQS that conducting a complete regulatory flexibility analysis is not feasible for rules setting or revising a NAAQS.

therefore appropriately certified the rule. Further, as required by the Clean Air Act, EPA is promulgating this final rule under section 307(d) of the Clean Air Act. For all the foregoing reasons, EPA has not prepared a final regulatory flexibility analysis for the rule. The Agency has nonetheless analyzed in the final RIA for the rule the potential impact on small entities of hypothetical State plans for implementing the NAAQS. The Agency also plans to issue guidance to the States on reducing the potential impact on small entities of implementing the NAAQS.

C. Impact on Reporting Requirements

There are no reporting requirements directly associated with the finalization of ambient air quality standards under section 109 of the Act (42 U.S.C. 7400). There are, however, reporting requirements associated with related sections of the Act, particularly sections 107, 110, 160, and 317 (42 U.S.C. 7407, 7410, 7460, and 7617).

In EPA's final revisions to the air quality surveillance requirements (40 CFR part 58) for PM, the associated RIA addresses the Paperwork Reduction Act requirements through an Information Collection Request.

D. Unfunded Mandates Reform Act

Title II of the Unfunded Mandates Reform Act of 1995 (UMRA), Pub. L. 104–4, establishes requirements for Federal agencies to assess the effects of certain regulatory actions on State, local, and tribal governments and the private sector. Under section 202 of UMRA, EPA generally must prepare a written statement, including a cost-benefit analysis, for proposed and final rules with ''Federal mandates'' that may result in expenditures by State, local, and tribal governments, in the aggregate, or by the private sector, of $100 million or more in any 1 year. This requirement does not apply if EPA is prohibited by law from considering section 202 of UMRA estimates and analyses in adopting the rule in question. Before promulgating a final rule for which a written statement is needed, section 205 of UMRA generally requires EPA to identify and consider a reasonable number of regulatory alternatives and adopt the least costly, most cost-effective, or least burdensome alternative that achieves the objectives of the rule. These requirements do not apply when they are inconsistent with applicable law. Moreover, section 205 of UMRA allows EPA to adopt an alternative other than the least costly, most cost-effective, or least burdensome alternative if the Administrator publishes with the final rule an explanation of why that alternative was not adopted. Before EPA establishes any regulatory requirements that may significantly or uniquely affect small governments, including tribal governments, it must have developed under section 203 of UMRA a small government agency plan. The plan must provide for notifying potentially affected small governments, enabling officials of affected small governments to have meaningful and timely input in the development of EPA regulatory proposals with significant Federal intergovernmental mandates, and informing, educating, and advising small governments on compliance with the regulatory requirements. Section 204 of UMRA requires each agency to develop ''an effective process to permit elected officers of state, local and tribal governments * * * to provide meaningful and timely input'' in the development of regulatory proposals containing a significant Federal intergovernmental mandate.[99]

The EPA has determined that the provisions of sections 202 and 205 of UMRA do not apply to this decision.''Unless otherwise prohibited by law,'' EPA is to prepare a written statement under section 202 of UMRA that is to contain assessments and estimates of the costs and benefits of a rule containing a Federal mandate. Congress clarified that ''unless otherwise prohibited by law'' referred to whether an agency was prohibited from considering the information in the rulemaking process, not to whether an agency was prohibited from collecting the information. The Conference Report on UMRA states, ''This section [202] does not require the preparation of any estimate or analysis if the agency is prohibited by law from considering the estimate or analysis in adopting the rule.'' 141 Cong. Rec. H3063 (daily ed. March 13, 1995). Because the Clean Air Act prohibits EPA, when setting the NAAQS, from considering the types of estimates and assessments described in section 202 of UMRA, UMRA does not require EPA to prepare a written statement under section 202.[100] The requirements in section 205 of UMRA do not apply because those requirements only apply to rules ''for which a written statement is required under section 202 * * *.''

The EPA has determined that the provisions of section 203 of UMRA do not apply to this decision. Section 203 of UMRA only requires the development of a small government agency plan for requirements with which small governments might have to comply. Since setting the NAAQS does not establish requirements with which small governments might have to comply, section 203 of UMRA does not apply. The EPA acknowledges, however, that any corresponding revisions to associated SIP requirements and air quality surveillance requirements, 40 CFR parts 51 and 58, respectively, might result in such effects.Accordingly, EPA did address unfunded mandates when it proposed revisions to 40 CFR part 58, and will do so, as appropriate, when it proposes any revision to 40 CFR part 51.

With regard to the outreach described in section 204 of UMRA, EPA did follow a process for providing elected officials with an opportunity for meaningful and timely input into the proposed NAAQS revisions, although EPA did not describe this process in the proposal. The EPA conducted a series of pre-proposal outreach meetings with State and local officials and their representatives that permitted these officials to provide meaningful and timely input on issues related to the NAAQS and the monitoring issues associated with them. Beginning in January, 1996, EPA briefed State and local air pollution control officials at national meetings with State and Territorial Air Pollution Program Administrators (STAPPA) / Association of Local Air Pollution Control Officials (ALAPCO) in Washington, DC, North Carolina, Chicago, and Nevada. The EPA also held briefings for the Washington, DC representatives of several State and local organizations, including National Conference of State Legislators, U.S. Conference of Mayors,

[99] As noted in unit VIII.B., a NAAQS rule only establishes a standard of air quality that other provisions of the Act call on States (or in the case of State inaction, the Federal government) to achieve by adopting implementation plans containing specific control measures for the purpose. Thus, it is questionable whether the NAAQS itself imposes an enforceable duty and thus whether it is a significant Federal mandate within the meaning of UMRA. EPA need not and does not reach this issue in this document. For the reasons given in this unit, even if the NAAQS were determined to be a significant Federal mandate, EPA does not have any obligations under sections 202 and 205 of UMRA, and EPA has met any obligations it would have under section 204 of UMRA.

[100] In addition to the estimates and assessments described in section 202 of UMRA, written statements are also to include an identification of the Federal law under which the rule is promulgated (section 202(a)(1) of UMRA) and a description of outreach efforts under section 204 of UMRA (section 202(a)(5) of UMRA). Although these requirements do not apply here because a written statement is not required under section 202 of UMRA, this preamble identifies the Federal law under which this rule is being promulgated and a written statement describing EPA's outreach efforts with State, local, and tribal governments will be placed in the docket.

National Governors Association, National League of Cities, and STAPPA/ALAPCO. EPA also held separate briefings and discussions with State and local officials at meetings set up by the National Governors Association, the U.S. Conference of Mayors and the Council of State Governments. The EPA also conducted in-depth briefings at each EPA regional office and regional staff also had several meetings and discussions with their State counterparts about the standards. The efforts described in this paragraph of this preamble, which provided elected officials with opportunity for meaningful and timely input into the proposed NAAQS revisions, met any requirements imposed by section 204 of UMRA. The docket will contain a written statement describing these outreach efforts, including a summary of the comments and concerns presented by State, local, and tribal governments and a summary of EPA's evaluation of those comments and concerns.

Several commenters disagreed with EPA that sections 202, 203, and 205 of UMRA do not apply to this decision. These commenters argued that EPA is not prohibited from considering costs in setting NAAQS under the Clean Air Act and applicable judicial decisions. Some commenters also expressed the view that there is no conflict between UMRA and the Clean Air Act with regard to the NAAQS. These commenters argued that UMRA and the NAAQS can be harmonized by reading UMRA as an information gathering statute and that EPA should therefore perform the analyses required by UMRA, regardless of whether costs may be considered. Finally, at least one commenter argued that in past NAAQS reviews, EPA did not dispute its UMRA obligations.

As discussed more fully in Unit IV. of this preamble, EPA is prohibited from considering cost in setting the NAAQS. Given that fact (as noted in Unit IV. of this preamble), sections 202 and 205 of UMRA do not apply.[101] As the Conference Report clarifies, UMRA itself states that the section 202 estimates and analyses are not required in cases such as the NAAQS, where an agency is prohibited by law from considering section 202 estimates and analyses. Reading UMRA in the manner suggested by the commenters would effectively read this provision out of UMRA; UMRA contains an exception for rules like the NAAQS, it must be given effect.

With regard to EPA's position regarding UMRA in previous NAAQS review exercises, EPA simply made plain in those situations that because it did not plan on revising the NAAQS, it determined, without further review, that sections 202, 203, and 205 of UMRA did not apply. EPA thus stated that:

> Because the Administrator has decided not to revise the existing primary NAAQS for SO_2, this action will not impose any new expenditures on governments or on the private sector, or establish any new regulatory requirements affecting small governments. Accordingly, EPA has determined that the provisions of sections 202, 203 and 205 do not apply to this final decision.

61 FR 25566, 25577, May 22, 1996; see also 61 FR 52852, 52856, October 8, 1996 (Same statement for NO_2 NAAQS). As this statement makes clear, EPA only determined that sections 202, 203, and 205 of UMRA did not apply to the NAAQS when EPA fails to revise the standard. Having made that determination, EPA had no reason to catalog additional bases for finding UMRA inapplicable. Nothing in that statement was intended to preclude EPA, or precludes EPA, from concluding for other reasons (such as those discussed in this unit) that UMRA also does not apply when EPA in fact revises an applicable NAAQS.

E. Environmental Justice

Executive Order 12848 (58 FR 7629, February 11, 1994) requires that each Federal agency make achieving environmental justice part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minorities and low-income populations. These requirements have been addressed to the extent practicable in the RIA cited in this unit.

F. Submission to Congress and the Comptroller General

Under 5 U.S.C. 801(a)(1)(A), as added by the Small Business Regulatory Enforcement Fairness Act of 1996 (SBREFA), EPA submitted a report containing this rule and other required information to the U.S. Senate, the U.S. House of Representatives, and the Comptroller General of the United States prior to publication of the rule in this issue of the **Federal Register**. This rule is a ''major rule'' for purposes of SBREFA.

IX. Response to Petition for Administrator Browner's Rescusal

On March 13, 1997, the Washington Legal Foundation (WLF), filed a petition with EPA asking that I, Carol Browner, disqualify myself in rulemaking regarding the NAAQS for PM and ozone. The petition claims that my public statements indicate a ''clear and convincing showing'' that I had ''already decided to revise the NAAQS for PM and ozone'' and that I therefore ''could not give meaningful consideration'' to comments adverse to the proposed rule. On May 12, 1997, EPA's General Counsel, Jonathan Z. Cannon, sent a letter to WLF regarding the petition. This letter and the WLF petition were then placed in the dockets for the proposed ozone and PM standards pending ''consideration and final response in connection with the Agency's final actions.''

Contrary to WLF's assertions, I have maintained an open mind throughout these proceedings, and have based today's decisions on the rulemaking record—including consideration of comments opposed to the proposal. The law does not require the Administrator of EPA to disqualify herself merely for expressing views on a proposed regulation; in fact, it is part of my responsibility to engage in the public debate on the proposals. Moreover, the assertions in WLF's petition do not accurately represent my views. The petition takes quotes out of context and repeatedly misinterprets my statements. For example, WLF quotes a statement that I made at the Children's Environmental Health Network Research Conference as an indication that I had ''prejudged the issue.'' However, my statement that ''I will not be swayed'' did not refer to adopting the NAAQS as proposed. Instead, as is clear from reviewing the entire speech, I was addressing my broader concern about children's health and the range of EPA standards affecting children's health. I also appeared at several congressional hearings and testified before members of Congress, some of whom were strongly opposed to the proposals. At those hearings, I explained the basis for the proposals and put forward the reasons why I concluded the proposals were appropriate, given the information before me at the time. At the same time, I made clear that I took very seriously

[101] One commenter argued that in reviewing the SO_2 NAAQS, EPA determined that it need not revise the $S0_2$ NAAQS, but could instead pursue an alternative regulatory program under other authority. This commenter argued that EPA has similar flexibility in reviewing the PM and Ozone NAAQS, and thus UMRA requires EPA to identify the least burdensome alternative (such as retaining the current NAAQS) as part of that process. As discussed more fully in Unit IV. of this preamble, EPA does not agree that it has flexibility to choose such an alternative; nor does EPA agree with the commenter's characterization of the action it took in deciding not to revise the SO_2 NAAQS. In fact, in deciding not to revise the SO_2 NAAQS, EPA determined, for reasons independent of section 303 of the Clean Air Act that a NAAQS revision was not warranted. See 61 FR 25566, 25575 (May 22, 1996).

my obligation to keep an open mind, and to consider fully and fairly all significant comments that the Agency received. For these reasons and others, as set forth in Mr. Cannon's May 12, 1997 response to WLF, which I adopt in full, I have decided not to recuse myself from any aspect of considering revisions to the NAAQS for ozone and PM. Accordingly, I am hereby denying WLF's petition.

List of Subjects in 40 CFR Part 50

Environmental protection, Air pollution control, Carbon monoxide, Lead, Nitrogen dioxide, Ozone, Particulate matter, Sulfur oxides.

Dated: July 16, 1997.

Carol M. Browner,

Administrator.

Therefore, 40 CFR Chapter I is amended as follows:

PART 50—NATIONAL PRIMARY AND SECONDARY AMBIENT AIR QUALITY STANDARDS

1. The authority citation for part 50 continues to read as follows:

Authority: Secs. 109 and 301(a), Clean Air Act, as amended (42 U.S.C. 7409, 7601(a)).

2. Section 50.3 is revised to read as follows:

§ 50.3 Reference conditions.

All measurements of air quality that are expressed as mass per unit volume (e.g., micrograms per cubic meter) other than for the particulate matter (PM_{10} and $PM_{2.5}$) standards contained in § 50.7 shall be corrected to a reference temperature of 25 °C and a reference pressure of 760 millimeters of mercury (1,013.2 millibars). Measurements of PM_{10} and $PM_{2.5}$ for purposes of comparison to the standards contained in § 50.7 shall be reported based on actual ambient air volume measured at the actual ambient temperature and pressure at the monitoring site during the measurement period.

3. Section 50.6 is amended by revising the section heading and adding paragraph (d) to read as follows:

§ 50.6 National primary and secondary ambient air quality standards for PM_{10}.

* * * * *

(d) The PM_{10} standards set forth in this section will no longer apply to an area not attaining these standards as of September 16, 1997, once EPA takes final action to promulgate a rule pursuant to section 172(e) of the Clean Air Act, as amended (42 U.S.C. 7472(e)) applicable to the area. The PM_{10} standards set forth in this section will no longer apply to an area attaining these standards as of September 16, 1997, once EPA approves a State Implementation Plan (SIP) applicable to the area containing all PM_{10} control measures adopted and implemented by the state prior to September 16, 1997, and a section 110 SIP implementing the PM standards published on July 18, 1997. SIP approvals are codified in 40 CFR part 52.

4. Section 50.7 is added to read as follows:

§ 50.7 National primary and secondary ambient air quality standards for particulate matter.

(a) The national primary and secondary ambient air quality standards for particulate matter are:

(1) 15.0 micrograms per cubic meter ($\mu g/m^3$) annual arithmetic mean concentration, and 65 $\mu g/m^3$ 24-hour average concentration measured in the ambient air as $PM_{2.5}$ (particles with an aerodynamic diameter less than or equal to a nominal 2.5 micrometers) by either:

(i) A reference method based on Appendix L of this part and designated in accordance with part 53 of this chapter; or

(ii) An equivalent method designated in accordance with part 53 of this chapter.

(2) 50 micrograms per cubic meter ($\mu g/m^3$) annual arithmetic mean

concentration, and 150 μg/m^3 24-hour average concentration measured in the ambient air as PM_{10} (particles with an aerodynamic diameter less than or equal to a nominal 10 micrometers) by either:

(i) A reference method based on Appendix M of this part and designated in accordance with part 53 of this chapter; or

(ii) An equivalent method designated in accordance with part 53 of this chapter.

(b) The annual primary and secondary $PM_{2.5}$ standards are met when the annual arithmetic mean concentration, as determined in accordance with Appendix N of this part, is less than or equal to 15.0 micrograms per cubic meter.

(c) The 24-hour primary and secondary $PM_{2.5}$ standards are met when the 98th percentile 24-hour concentration, as determined in accordance with Appendix N of this part, is less than or equal to 65 micrograms per cubic meter.

(d) The annual primary and secondary PM_{10} standards are met when the annual arithmetic mean concentration, as determined in accordance with Appendix N of this part, is less than or equal to 50 micrograms per cubic meter.

(e) The 24-hour primary and secondary PM_{10} standards are met when the 99th percentile 24-hour concentration, as determined in accordance with Appendix N of this part, is less than or equal to 150 micrograms per cubic meter.

5. Appendix K is revised (for conformity with the format of the other appendices in this part) to read as follows:

Appendix K to Part 50—Interpretation of the National Ambient Air Quality Standards for Particulate Matter

1.0 *General.*

(a) This appendix explains the computations necessary for analyzing particulate matter data to determine attainment of the 24-hour and annual standards specified in 40 CFR 50.6. For the primary and secondary standards, particulate matter is measured in the ambient air as PM_{10} (particles with an aerodynamic diameter less than or equal to a nominal 10 micrometers) by a reference method based on appendix J of this part and designated in accordance with part 53 of this chapter, or by an equivalent method designated in accordance with part 53 of this chapter. The required frequency of measurements is specified in part 58 of this chapter.

(b) The terms used in this appendix are defined as follows:

Average refers to an arithmetic mean. All particulate matter standards are expressed in terms of expected annual values: Expected number of exceedances per year for the 24-hour standards and expected annual arithmetic mean for the annual standards.

Daily value for PM_{10} refers to the 24-hour average concentration of PM_{10} calculated or measured from midnight to midnight (local time).

Exceedance means a daily value that is above the level of the 24-hour standard after rounding to the nearest 10 μg/m^3 (i.e., values ending in 5 or greater are to be rounded up).

Expected annual value is the number approached when the annual values from an increasing number of years are averaged, in the absence of long-term trends in emissions or meteorological conditions.

Year refers to a calendar year.

(c) Although the discussion in this appendix focuses on monitored data, the same principles apply to modeling data, subject to EPA modeling guidelines.

2.0 *Attainment Determinations.*

2.1 *24-Hour Primary and Secondary Standards.*

(a) Under 40 CFR 50.6(a) the 24-hour primary and secondary standards are attained when the expected number of exceedances per year at each monitoring site is less than or equal to one. In the simplest case, the number of expected exceedances at a site is determined by recording the number of exceedances in each calendar year and then averaging them over the past 3 calendar years. Situations in which 3 years of data are not available and possible adjustments for unusual events or trends are discussed in sections 2.3 and 2.4 of this appendix. Further, when data for a year are incomplete, it is necessary to compute an estimated number of exceedances for that year by adjusting the observed number of exceedances. This procedure, performed by calendar quarter, is described in section 3.0 of this appendix. The expected number of exceedances is then estimated by averaging the individual annual estimates for the past 3 years.

(b) The comparison with the allowable expected exceedance rate of one per year is made in terms of a number rounded to the nearest tenth (fractional values equal to or greater than 0.05 are to be rounded up; e.g., an exceedance rate of 1.05 would be rounded to 1.1, which is the lowest rate for nonattainment).

2.2 *Annual Primary and Secondary Standards.* Under 40 CFR 50.6(b), the annual primary and secondary standards are attained when the expected annual arithmetic mean PM_{10} concentration is less than or equal to the level of the standard. In the simplest case, the expected annual arithmetic mean is determined by averaging the annual arithmetic mean PM_{10} concentrations for the past 3 calendar years. Because of the potential for incomplete data and the possible seasonality in PM_{10} concentrations, the annual mean shall be calculated by averaging the four quarterly means of PM_{10} concentrations within the calendar year. The equations for calculating the annual arithmetic mean are given in section 4.0 of this appendix. Situations in which 3 years of data are not available and possible adjustments for unusual events or trends are discussed in sections 2.3 and 2.4 of this appendix. The expected annual arithmetic mean is rounded to the nearest 1 μg/m^3 before comparison with the annual standards (fractional values equal to or greater than 0.5 are to be rounded up).

2.3 *Data Requirements.*

(a) 40 CFR 58.13 specifies the required minimum frequency of sampling for PM_{10}. For the purposes of making comparisons with the particulate matter standards, all data produced by National Air Monitoring Stations (NAMS), State and Local Air Monitoring Stations (SLAMS) and other sites submitted to EPA in accordance with the Part 58 requirements must be used, and a minimum of 75 percent of the scheduled PM_{10} samples per quarter are required.

(b) To demonstrate attainment of either the annual or 24-hour standards at a monitoring site, the monitor must provide sufficient data to perform the required calculations of sections 3.0 and 4.0 of this appendix. The amount of data required varies with the sampling frequency, data capture rate and the number of years of record. In all cases, 3 years of representative monitoring data that meet the 75 percent criterion of the previous paragraph should be utilized, if available, and would suffice. More than 3 years may be considered, if all additional representative years of data meeting the 75 percent criterion are utilized. Data not meeting these criteria may also suffice to show attainment; however, such exceptions will have to be approved by the appropriate Regional Administrator in accordance with EPA guidance.

(c) There are less stringent data requirements for showing that a monitor has failed an attainment test and thus has recorded a violation of the particulate matter standards. Although it is generally necessary to meet the minimum 75 percent data capture requirement per quarter to use the computational equations described in sections 3.0 and 4.0 of this appendix, this criterion does not apply when less data is sufficient to unambiguously establish nonattainment. The following examples illustrate how nonattainment can be demonstrated when a site fails to meet the completeness criteria. Nonattainment of the 24-hour primary standards can be established by the observed annual number of exceedances (e.g., four observed exceedances in a single year), or by the estimated number of exceedances derived from the observed number of exceedances and the required number of scheduled samples (e.g., two observed exceedances with every other day sampling). Nonattainment of the annual standards can be demonstrated on the basis of quarterly mean concentrations developed from observed data combined with one-half the minimum detectable concentration substituted for missing values. In both cases, expected annual values must exceed the levels allowed by the standards.

2.4 *Adjustment for Exceptional Events and Trends.*

(a) An exceptional event is an uncontrollable event caused by natural sources of particulate matter or an event that is not expected to recur at a given location. Inclusion of such a value in the computation of exceedances or averages could result in inappropriate estimates of their respective expected annual values. To reduce the effect of unusual events, more than 3 years of

representative data may be used. Alternatively, other techniques, such as the use of statistical models or the use of historical data could be considered so that the event may be discounted or weighted according to the likelihood that it will recur. The use of such techniques is subject to the approval of the appropriate Regional Administrator in accordance with EPA guidance.

(b) In cases where long–term trends in emissions and air quality are evident, mathematical techniques should be applied to account for the trends to ensure that the expected annual values are not inappropriately biased by unrepresentative data. In the simplest case, if 3 years of data are available under stable emission conditions, this data should be used. In the event of a trend or shift in emission patterns, either the most recent representative year(s) could be used or statistical techniques or models could be used in conjunction with previous years of data to adjust for trends. The use of less than 3 years of data, and any adjustments are subject to the approval of the appropriate Regional Administrator in accordance with EPA guidance.

3.0 *Computational Equations for the 24-hour Standards.*

3.1 *Estimating Exceedances for a Year.*

(a) If PM_{10} sampling is scheduled less frequently than every day, or if some scheduled samples are missed, a PM_{10} value will not be available for each day of the year. To account for the possible effect of incomplete data, an adjustment must be made to the data collected at each monitoring location to estimate the number of exceedances in a calendar year. In this adjustment, the assumption is made that the fraction of missing values that would have exceeded the standard level is identical to the fraction of measured values above this level. This computation is to be made for all sites that are scheduled to monitor throughout the entire year and meet the minimum data requirements of section 2.3 of this appendix. Because of possible seasonal imbalance, this adjustment shall be applied on a quarterly basis. The estimate of the expected number of exceedances for the quarter is equal to the observed number of exceedances plus an increment associated with the missing data. The following equation must be used for these computations:

Equation 1

$$e_q = v_q + \left[\left(v_q/n_q\right)\times\left(N_q - n_q\right)\right] = v_q \times N_q/n_q$$

where:

e_q=the estimated number of exceedances for calendar quarter q;

v_q=the observed number of exceedances for calendar quarter q;

N_q=the number of days in calendar quarter q;

n_q=the number of days in calendar quarter q with PM_{10} data; and

q=the index for calendar quarter, q=1, 2, 3 or 4.

(b) The estimated number of exceedances for a calendar quarter must be rounded to the nearest hundredth (fractional values equal to or greater than 0.005 must be rounded up).

(c) The estimated number of exceedances for the year, e, is the sum of the estimates for each calendar quarter.

Equation 2

$$e = \sum_{q=1}^{4} e_q$$

(d) The estimated number of exceedances for a single year must be rounded to one decimal place (fractional values equal to or greater than 0.05 are to be rounded up). The expected number of exceedances is then estimated by averaging the individual annual estimates for the most recent 3 or more representative years of data. The expected number of exceedances must be rounded to one decimal place (fractional values equal to or greater than 0.05 are to be rounded up).

(e) The adjustment for incomplete data will not be necessary for monitoring or modeling data which constitutes a complete record, i.e., 365 days per year.

(f) To reduce the potential for overestimating the number of expected exceedances, the correction for missing data will not be required for a calendar quarter in which the first observed exceedance has occurred if:

(1) There was only one exceedance in the calendar quarter;

(2) Everyday sampling is subsequently initiated and maintained for 4 calendar quarters in accordance with 40 CFR 58.13; and

(3) Data capture of 75 percent is achieved during the required period of everyday sampling. In addition, if the first exceedance is observed in a calendar quarter in which the monitor is already sampling every day, no adjustment for missing data will be made to the first exceedance if a 75 percent data capture rate was achieved in the quarter in which it was observed.

Example 1

a. During a particular calendar quarter, 39 out of a possible 92 samples were recorded, with one observed exceedance of the 24-hour standard. Using Equation 1, the estimated number of exceedances for the quarter is:

e_q=1×92/39=2.359 or 2.36.

b. If the estimated exceedances for the other 3 calendar quarters in the year were 2.30, 0.0 and 0.0, then, using Equation 2, the estimated number of exceedances for the year is 2.36+2.30+0.0+0.0 which equals 4.66 or 4.7. If no exceedances were observed for the 2 previous years, then the expected number of exceedances is estimated by: (1/3)×(4.7+0+0)=1.57 or 1.6. Since 1.6 exceeds the allowable number of expected exceedances, this monitoring site would fail the attainment test.

Example 2

In this example, everyday sampling was initiated following the first observed exceedance as required by 40 CFR 58.13. Accordingly, the first observed exceedance would not be adjusted for incomplete sampling. During the next three quarters, 1.2 exceedances were estimated. In this case, the estimated exceedances for the year would be 1.0+1.2+0.0+0.0 which equals 2.2. If, as before, no exceedances were observed for the two previous years, then the estimated exceedances for the 3–year period would then be (1/3)×(2.2+0.0+0.0)=0.7, and the monitoring site would *not* fail the attainment test.

3.2 *Adjustments for Non-Scheduled Sampling Days.*

(a) If a systematic sampling schedule is used and sampling is performed on days in addition to the days specified by the systematic sampling schedule, e.g., during episodes of high pollution, then an adjustment must be made in the eqution for the estimation of exceedances. Such an adjustment is needed to eliminate the bias in the estimate of the quarterly and annual number of exceedances that would occur if the chance of an exceedance is different for scheduled than for non-scheduled days, as would be the case with episode sampling.

(b) The required adjustment treats the systematic sampling schedule as a stratified sampling plan. If the period from one scheduled sample until the day preceding the next scheduled sample is defined as a sampling stratum, then there is one stratum for each scheduled sampling day. An average number of observed exceedances is computed for each of these sampling strata. With nonscheduled sampling days, the estimated number of exceedances is defined as:

Equation 3

$$e_q = \left(N_q/m_q\right)\times\sum_{j=1}^{m_q}\left(v_j/k_j\right)$$

where:

e_q=the estimated number of exceedances for the quarter;

N_q=the number of days in the quarter;

m_q=the number of strata with samples during the quarter;

v_j=the number of observed exceedances in stratum j; and

k_j=the number of actual samples in stratum j.

(c) Note that if only one sample value is recorded in each stratum, then Equation 3 reduces to Equation 1.

Example 3

A monitoring site samples according to a systematic sampling schedule of one sample every 6 days, for a total of 15 scheduled samples in a quarter out of a total of 92 possible samples. During one 6-day period, potential episode levels of PM_{10} were suspected, so 5 additional samples were taken. One of the regular scheduled samples was missed, so a total of 19 samples in 14 sampling strata were measured. The one 6-day sampling stratum with 6 samples recorded 2 exceedances. The remainder of the quarter with one sample per stratum recorded zero exceedances. Using Equation 3, the estimated number of exceedances for the quarter is:

e_q=(92/14)×(2/6+0+. . .+0)=2.19.

4.0 *Computational Equations for Annual Standards.*

4.1 *Calculation of the Annual Arithmetic Mean.* (a) An annual arithmetic mean value for PM_{10} is determined by averaging the quarterly means for the 4 calendar quarters of the year. The following equation is to be used for calculation of the mean for a calendar quarter:

Equation 4

$$\bar{x}_q = \left(1/n_q\right) \times \sum_{i=1}^{n_q} x_i$$

where:

$\bar{x}_q$= the quarterly mean concentration for quarter q, q=1, 2, 3, or 4,

n_q= the number of samples in the quarter, and

x_i= the ith concentration value recorded in the quarter.

(b) The quarterly mean, expressed in μg/m^3, must be rounded to the nearest tenth (fractional values of 0.05 should be rounded up).

(c) The annual mean is calculated by using the following equation:

Equation 5

$$\bar{x} = \left(1/4\right) \times \sum_{q=1}^{4} \bar{x}_q$$

where:

$\bar{x}$=the annual mean; and

$\bar{x}_q$=the mean for calendar quarter q.

(d) The average of quarterly means must be rounded to the nearest tenth (fractional values of 0.05 should be rounded up).

(e) The use of quarterly averages to compute the annual average will not be necessary for monitoring or modeling data which results in a complete record, i.e., 365 days per year.

(f) The expected annual mean is estimated as the average of three or more annual means. This multi-year estimate, expressed in μg/m^3, shall be rounded to the nearest integer for comparison with the annual standard (fractional values of 0.5 should be rounded up).

Example 4

Using Equation 4, the quarterly means are calculated for each calendar quarter. If the quarterly means are 52.4, 75.3, 82.1, and 63.2 μg/m^3, then the annual mean is:

$\bar{x}$ = (1/4)×(52.4+75.3+82.1+63.2)= 68.25 or 68.3.

4.2 *Adjustments for Non-scheduled Sampling Days.* (a) An adjustment in the calculation of the annual mean is needed if sampling is performed on days in addition to the days specified by the systematic sampling schedule. For the same reasons given in the discussion of estimated exceedances, under section 3.2 of this appendix, the quarterly averages would be calculated by using the following equation:

Equation 6

$$\bar{x}_q = \left(1/m_q\right) \times \sum_{j=1}^{m_q} \sum_{i=1}^{k_j} \left(x_{ij}/k_j\right)$$

where:

$\bar{x}_q$=the quarterly mean concentration for quarter q, q=1, 2, 3, or 4;

x_{ij}=the ith concentration value recorded in stratum j;

k_j=the number of actual samples in stratum j; and

m_q=the number of strata with data in the quarter.

(b) If one sample value is recorded in each stratum, Equation 6 reduces to a simple arithmetic average of the observed values as described by Equation 4.

Example 5

a. During one calendar quarter, 9 observations were recorded. These samples were distributed among 7 sampling strata, with 3 observations in one stratum. The concentrations of the 3 observations in the single stratum were 202, 242, and 180 μg/m^3. The remaining 6 observed concentrations were 55, 68, 73, 92, 120, and 155 μg/m^3. Applying the weighting factors specified in Equation 6, the quarterly mean is:

$\bar{x}_q$ = (1/7) × [(1/3) × (202 + 242 + 180) + 155 + 68 + 73 + 92 + 120 + 155] = 110.1

b. Although 24–hour measurements are rounded to the nearest 10 μg/m^3 for determinations of exceedances of the 24–hour standard, note that these values are rounded to the nearest 1 μg/m^3 for the calculation of means.

6. Appendix L is added to read as follows:

Appendix L to Part 50—Reference Method For the Determination of Fine Particulate Matter as $PM_{2.5}$ in the Atmosphere

1.0 *Applicability.*

1.1 This method provides for the measurement of the mass concentration of fine particulate matter having an aerodynamic diameter less than or equal to a nominal 2.5 micrometers ($PM_{2.5}$) in ambient air over a 24-hour period for purposes of determining whether the primary and secondary national ambient air quality standards for fine particulate matter specified in § 50.6 of this part are met. The measurement process is considered to be nondestructive, and the $PM_{2.5}$ sample obtained can be subjected to subsequent physical or chemical analyses. Quality assessment procedures are provided in part 58, Appendix A of this chapter, and quality assurance guidance are provided in references 1, 2, and 3 in section 13.0 of this appendix.

1.2 This method will be considered a reference method for purposes of part 58 of this chapter only if:

(a) The associated sampler meets the requirements specified in this appendix and the applicable requirements in part 53 of this chapter, and

(b) The method and associated sampler have been designated as a reference method in accordance with part 53 of this chapter.

1.3 $PM_{2.5}$ samplers that meet nearly all specifications set forth in this method but have minor deviations and/or modifications of the reference method sampler will be designated as ''Class I'' equivalent methods for $PM_{2.5}$ in accordance with part 53 of this chapter.

2.0 *Principle.*

2.1 An electrically powered air sampler draws ambient air at a constant volumetric flow rate into a specially shaped inlet and through an inertial particle size separator (impactor) where the suspended particulate matter in the $PM_{2.5}$ size range is separated for collection on a polytetrafluoroethylene (PTFE) filter over the specified sampling period. The air sampler and other aspects of this reference method are specified either explicitly in this appendix or generally with reference to other applicable regulations or quality assurance guidance.

2.2 Each filter is weighed (after moisture and temperature conditioning) before and after sample collection to determine the net gain due to collected $PM_{2.5}$. The total volume of air sampled is determined by the sampler from the measured flow rate at actual ambient temperature and pressure and the sampling time. The mass concentration of $PM_{2.5}$ in the ambient air is computed as the total mass of collected particles in the $PM_{2.5}$ size range divided by the actual volume of air sampled, and is expressed in micrograms per cubic meter of air (μg/m^3).

3.0 *$PM_{2.5}$ Measurement Range.*

3.1 *Lower concentration limit.* The lower detection limit of the mass concentration measurement range is estimated to be approximately 2 μg/am^3, based on noted mass changes in field blanks in conjunction with the 24 m^3 nominal total air sample volume specified for the 24-hour sample.

3.2 *Upper concentration limit.* The upper limit of the mass concentration range is determined by the filter mass loading beyond which the sampler can no longer maintain the operating flow rate within specified limits due to increased pressure drop across the loaded filter. This upper limit cannot be specified precisely because it is a complex function of the ambient particle size distribution and type, humidity, the individual filter used, the capacity of the sampler flow rate control system, and perhaps other factors. Nevertheless, all samplers are estimated to be capable of measuring 24-hour $PM_{2.5}$ mass concentrations of at least 200 μg/m^3 while maintaining the operating flow rate within the specified limits.

3.3 *Sample period.* The required sample period for $PM_{2.5}$ concentration measurements by this method shall be 1,380 to 1500 minutes (23 to 25 hours). However, when a sample period is less than 1,380 minutes, the measured concentration (as determined by the collected $PM_{2.5}$ mass divided by the actual sampled air volume), multiplied by the actual number of minutes in the sample period and divided by 1,440, may be used as if it were a valid concentration measurement for the specific purpose of determining a violation of the NAAQS. This value assumes

that the $PM_{2.5}$ concentration is zero for the remaining portion of the sample period and therefore represents the minimum concentration that could have been measured for the full 24-hour sample period. Accordingly, if the value thus calculated is high enough to be an exceedance, such an exceedance would be a valid exceedance for the sample period. When reported to AIRS, this data value should receive a special code to identify it as not to be commingled with normal concentration measurements or used for other purposes.

4.0 *Accuracy.*

4.1 Because the size and volatility of the particles making up ambient particulate matter vary over a wide range and the mass concentration of particles varies with particle size, it is difficult to define the accuracy of $PM_{2.5}$ measurements in an absolute sense. The accuracy of $PM_{2.5}$ measurements is therefore defined in a relative sense, referenced to measurements provided by this reference method. Accordingly, accuracy shall be defined as the degree of agreement between a subject field $PM_{2.5}$ sampler and a collocated $PM_{2.5}$ reference method audit sampler operating simultaneously at the monitoring site location of the subject sampler and includes both random (precision) and systematic (bias) errors. The requirements for this field sampler audit procedure are set forth in part 58, Appendix A of this chapter.

4.2 Measurement system bias. Results of collocated measurements where the duplicate sampler is a reference method sampler are used to assess a portion of the measurement system bias according to the schedule and procedure specified in part 58, Appendix A of this chapter.

4.3 Audits with reference method samplers to determine system accuracy and bias. According to the schedule and procedure specified in part 58, Appendix A of this chapter, a reference method sampler is required to be located at each of selected $PM_{2.5}$ SLAMS sites as a duplicate sampler. The results from the primary sampler and the duplicate reference method sampler are used to calculate accuracy of the primary sampler on a quarterly basis, bias of the primary sampler on an annual basis, and bias of a single reporting organization on an annual basis. Reference 2 in section 13.0 of this appendix provides additional information and guidance on these reference method audits.

4.4 Flow rate accuracy and bias. Part 58, Appendix A of this chapter requires that the flow rate accuracy and bias of individual $PM_{2.5}$ samplers used in SLAMS monitoring networks be assessed periodically via audits of each sampler's operational flow rate. In addition, part 58, Appendix A of this chapter requires that flow rate bias for each reference and equivalent method operated by each reporting organization be assessed quarterly and annually. Reference 2 in section 13.0 of this appendix provides additional information and guidance on flow rate accuracy audits and calculations for accuracy and bias.

5.0 *Precision.* A data quality objective of 10 percent coefficient of variation or better has been established for the operational precision of $PM_{2.5}$ monitoring data.

5.1 Tests to establish initial operational precision for each reference method sampler are specified as a part of the requirements for designation as a reference method under § 53.58 of this chapter.

5.2 Measurement System Precision. Collocated sampler results, where the duplicate sampler is not a reference method sampler but is a sampler of the same designated method as the primary sampler, are used to assess measurement system precision according to the schedule and procedure specified in part 58, Appendix A of this chapter. Part 58, Appendix A of this chapter requires that these collocated sampler measurements be used to calculate quarterly and annual precision estimates for each primary sampler and for each designated method employed by each reporting organization. Reference 2 in section 13.0 of this appendix provides additional information and guidance on this requirement.

6.0 *Filter for $PM_{2.5}$ Sample Collection.* Any filter manufacturer or vendor who sells or offers to sell filters specifically identified for use with this $PM_{2.5}$ reference method shall certify that the required number of filters from each lot of filters offered for sale as such have been tested as specified in this section 6.0 and meet all of the following design and performance specifications.

6.1 *Size.* Circular, 46.2 mm diameter ±0.25 mm.

6.2 *Medium.* Polytetrafluoroethylene (PTFE Teflon), with integral support ring.

6.3 *Support ring.* Polymethylpentene (PMP) or equivalent inert material, 0.38 ±0.04 mm thick, outer diameter 46.2 mm ±0.25 mm, and width of 3.68 mm (±0.00, -0.51 mm).

6.4 *Pore size.* 2 µm as measured by ASTM F 316–94.

6.5 *Filter thickness.* 30 to 50 µm.

6.6 *Maximum pressure drop (clean filter).* 30 cm H_2O column @ 16.67 L/min clean air flow.

6.7 *Maximum moisture pickup.* Not more than 10 µg weight increase after 24-hour exposure to air of 40 percent relative humidity, relative to weight after 24-hour exposure to air of 35 percent relative humidity.

6.8 *Collection efficiency.* Greater than 99.7 percent, as measured by the DOP test (ASTM D 2986–91) with 0.3 µm particles at the sampler's operating face velocity.

6.9 *Filter weight stability.* Filter weight loss shall be less than 20 µg, as measured in each of the following two tests specified in sections 6.9.1 and 6.9.2 of this appendix. The following conditions apply to both of these tests: Filter weight loss shall be the average difference between the initial and the final filter weights of a random sample of test filters selected from each lot prior to sale. The number of filters tested shall be not less than 0.1 percent of the filters of each manufacturing lot, or 10 filters, whichever is greater. The filters shall be weighed under laboratory conditions and shall have had no air sample passed through them, i.e., filter blanks. Each test procedure must include initial conditioning and weighing, the test, and final conditioning and weighing. Conditioning and weighing shall be in accordance with sections 8.0 through 8.2 of this appendix and general guidance provided in reference 2 of section 13.0 of this appendix.

6.9.1 *Test for loose, surface particle contamination.* After the initial weighing, install each test filter, in turn, in a filter cassette (Figures L–27, L–28, and L–29 of this appendix) and drop the cassette from a height of 25 cm to a flat hard surface, such as a particle-free wood bench. Repeat two times, for a total of three drop tests for each test filter. Remove the test filter from the cassette and weigh the filter. The average change in weight must be less than 20 µg.

6.9.2 *Test for temperature stability.* After weighing each filter, place the test filters in a drying oven set at 40 °C ±2 °C for not less than 48 hours. Remove, condition, and reweigh each test filter. The average change in weight must be less than 20 µg.

6.10 *Alkalinity.* Less than 25 microequivalents/gram of filter, as measured by the guidance given in reference 2 in section 13.0 of this appendix.

6.11 *Supplemental requirements.* Although not required for determination of $PM_{2.5}$ mass concentration under this reference method, additional specifications for the filter must be developed by users who intend to subject $PM_{2.5}$ filter samples to subsequent chemical analysis. These supplemental specifications include background chemical contamination of the filter and any other filter parameters that may be required by the method of chemical analysis. All such supplemental filter specifications must be compatible with and secondary to the primary filter specifications given in this section 6.0 of this appendix.

7.0 *$PM_{2.5}$ Sampler.*

7.1 *Configuration.* The sampler shall consist of a sample air inlet, downtube, particle size separator (impactor), filter holder assembly, air pump and flow rate control system, flow rate measurement device, ambient and filter temperature monitoring system, barometric pressure measurement system, timer, outdoor environmental enclosure, and suitable mechanical, electrical, or electronic control capability to meet or exceed the design and functional performance as specified in this section 7.0 of this appendix. The performance specifications require that the sampler:

(a) Provide automatic control of sample volumetric flow rate and other operational parameters.

(b) Monitor these operational parameters as well as ambient temperature and pressure.

(c) Provide this information to the sampler operator at the end of each sample period in digital form, as specified in Table L–1 of section 7.4.19 of this appendix.

7.2 *Nature of specifications.* The $PM_{2.5}$ sampler is specified by a combination of design and performance requirements. The sample inlet, downtube, particle size discriminator, filter cassette, and the internal configuration of the filter holder assembly are specified explicitly by design figures and associated mechanical dimensions, tolerances, materials, surface finishes, assembly instructions, and other necessary specifications. All other aspects of the

sampler are specified by required operational function and performance, and the design of these other aspects (including the design of the lower portion of the filter holder assembly) is optional, subject to acceptable operational performance. Test procedures to demonstrate compliance with both the design and performance requirements are set forth in subpart E of part 53 of this chapter.

7.3 *Design specifications.* Except as indicated in this section 7.3 of this appendix, these components must be manufactured or reproduced exactly as specified, in an ISO 9001-registered facility, with registration initially approved and subsequently maintained during the period of manufacture. See § 53.1(t) of this chapter for the definition of an ISO-registered facility. Minor modifications or variances to one or more components that clearly would not affect the aerodynamic performance of the inlet, downtube, impactor, or filter cassette will be considered for specific approval. Any such proposed modifications shall be described and submitted to the EPA for specific individual acceptability either as part of a reference or equivalent method application under part 53 of this chapter or in writing in advance of such an intended application under part 53 of this chapter.

7.3.1 *Sample inlet assembly.* The sample inlet assembly, consisting of the inlet, downtube, and impactor shall be configured and assembled as indicated in Figure L–1 of this appendix and shall meet all associated requirements. A portion of this assembly shall also be subject to the maximum overall sampler leak rate specification under section 7.4.6 of this appendix.

7.3.2 *Inlet.* The sample inlet shall be fabricated as indicated in Figures L–2 through L–18 of this appendix and shall meet all associated requirements.

7.3.3 *Downtube.* The downtube shall be fabricated as indicated in Figure L–19 of this appendix and shall meet all associated requirements.

7.3.4 *Impactor.*

7.3.4.1 The impactor (particle size separator) shall be fabricated as indicated in Figures L–20 through L–24 of this appendix and shall meet all associated requirements. Following the manufacture and finishing of each upper impactor housing (Figure L–21 of this appendix), the dimension of the impaction jet must be verified by the manufacturer using Class ZZ go/no-go plug gauges that are traceable to NIST.

7.3.4.2 Impactor filter specifications:

(a) Size. Circular, 35 to 37 mm diameter.

(b) Medium. Borosilicate glass fiber, without binder.

(c) Pore size. 1 to 1.5 micrometer, as measured by ASTM F 316–80.

(d) Thickness. 300 to 500 micrometers.

7.3.4.3 Impactor oil specifications:

(a) Composition. Tetramethyltetraphenyltrisiloxane, single-compound diffusion oil.

(b) Vapor pressure. Maximum 2 x 10^{-8} mm Hg at 25 °C.

(c) Viscosity. 36 to 40 centistokes at 25 °C.

(d) Density. 1.06 to 1.07 g/cm^3 at 25 °C.

(e) Quantity. 1 mL ±0.1 mL.

7.3.5 *Filter holder assembly.* The sampler shall have a sample filter holder assembly to adapt and seal to the down tube and to hold and seal the specified filter, under section 6.0 of this appendix, in the sample air stream in a horizontal position below the downtube such that the sample air passes downward through the filter at a uniform face velocity. The upper portion of this assembly shall be fabricated as indicated in Figures L–25 and L–26 of this appendix and shall accept and seal with the filter cassette, which shall be fabricated as indicated in Figures L–27 through L–29 of this appendix.

(a) The lower portion of the filter holder assembly shall be of a design and construction that:

(1) Mates with the upper portion of the assembly to complete the filter holder assembly,

(2) Completes both the external air seal and the internal filter cassette seal such that all seals are reliable over repeated filter changings, and

(3) Facilitates repeated changing of the filter cassette by the sampler operator.

(b) Leak–test performance requirements for the filter holder assembly are included in section 7.4.6 of this appendix.

(c) If additional or multiple filters are stored in the sampler as part of an automatic sequential sample capability, all such filters, unless they are currently and directly installed in a sampling channel or sampling configuration (either active or inactive), shall be covered or (preferably) sealed in such a way as to:

(1) Preclude significant exposure of the filter to possible contamination or accumulation of dust, insects, or other material that may be present in the ambient air, sampler, or sampler ventilation air during storage periods either before or after sampling; and

(2) To minimize loss of volatile or semi-volatile PM sample components during storage of the filter following the sample period.

7.3.6 *Flow rate measurement adapter.* A flow rate measurement adapter as specified in Figure L–30 of this appendix shall be furnished with each sampler.

7.3.7 *Surface finish.* All internal surfaces exposed to sample air prior to the filter shall be treated electrolytically in a sulfuric acid bath to produce a clear, uniform anodized surface finish of not less than 1000 mg/ft^2 (1.08 mg/cm^2) in accordance with military standard specification (mil. spec.) 8625F, Type II, Class 1 in reference 4 of section 13.0 of this appendix. This anodic surface coating shall not be dyed or pigmented. Following anodization, the surfaces shall be sealed by immersion in boiling deionized water for not less than 15 minutes. Section 53.51(d)(2) of this chapter should also be consulted.

7.3.8 *Sampling height.* The sampler shall be equipped with legs, a stand, or other means to maintain the sampler in a stable, upright position and such that the center of the sample air entrance to the inlet, during sample collection, is maintained in a horizontal plane and is 2.0 ±0.2 meters above the floor or other horizontal supporting surface. Suitable bolt holes, brackets, tie-downs, or other means should be provided to facilitate mechanically securing the sample to the supporting surface to prevent toppling of the sampler due to wind.

7.4 *Performance specifications.*

7.4.1 *Sample flow rate.* Proper operation of the impactor requires that specific air velocities be maintained through the device. Therefore, the design sample air flow rate through the inlet shall be 16.67 L/min (1.000 m^3/hour) measured as actual volumetric flow rate at the temperature and pressure of the sample air entering the inlet.

7.4.2 *Sample air flow rate control system.* The sampler shall have a sample air flow rate control system which shall be capable of providing a sample air volumetric flow rate within the specified range, under section 7.4.1 of this appendix, for the specified filter, under section 6.0 of this appendix, at any atmospheric conditions specified, under section 7.4.7 of this appendix, at a filter pressure drop equal to that of a clean filter plus up to 75 cm water column (55 mm Hg), and over the specified range of supply line voltage, under section 7.4.15.1 of this appendix. This flow control system shall allow for operator adjustment of the operational flow rate of the sampler over a range of at least ±15 percent of the flow rate specified in section 7.4.1 of this appendix.

7.4.3 *Sample flow rate regulation.* The sample flow rate shall be regulated such that for the specified filter, under section 6.0 of this appendix, at any atmospheric conditions specified, under section 7.4.7 of this appendix, at a filter pressure drop equal to that of a clean filter plus up to 75 cm water column (55 mm Hg), and over the specified range of supply line voltage, under section 7.4.15.1 of this appendix, the flow rate is regulated as follows:

7.4.3.1 The volumetric flow rate, measured or averaged over intervals of not more than 5 minutes over a 24-hour period, shall not vary more than ±5 percent from the specified 16.67 L/min flow rate over the entire sample period.

7.4.3.2 The coefficient of variation (sample standard deviation divided by the mean) of the flow rate, measured over a 24-hour period, shall not be greater than 2 percent.

7.4.3.3 The amplitude of short-term flow rate pulsations, such as may originate from some types of vacuum pumps, shall be attenuated such that they do not cause significant flow measurement error or affect the collection of particles on the particle collection filter.

7.4.4 *Flow rate cut off.* The sampler's sample air flow rate control system shall terminate sample collection and stop all sample flow for the remainder of the sample period in the event that the sample flow rate deviates by more than 10 percent from the sampler design flow rate specified in section 7.4.1 of this appendix for more than 60 seconds. However, this sampler cut-off provision shall not apply during periods when the sampler is inoperative due to a temporary power interruption, and the elapsed time of the inoperative period shall not be included in the total sample time measured and reported by the sampler, under section 7.4.13 of this appendix.

7.4.5 *Flow rate measurement.*

7.4.5.1 The sampler shall provide a means to measure and indicate the instantaneous sample air flow rate, which shall be measured as volumetric flow rate at the

temperature and pressure of the sample air entering the inlet, with an accuracy of ±2 percent. The measured flow rate shall be available for display to the sampler operator at any time in either sampling or standby modes, and the measurement shall be updated at least every 30 seconds. The sampler shall also provide a simple means by which the sampler operator can manually start the sample flow temporarily during non-sampling modes of operation, for the purpose of checking the sample flow rate or the flow rate measurement system.

7.4.5.2 During each sample period, the sampler's flow rate measurement system shall automatically monitor the sample volumetric flow rate, obtaining flow rate measurements at intervals of not greater than 30 seconds.

(a) Using these interval flow rate measurements, the sampler shall determine or calculate the following flow-related parameters, scaled in the specified engineering units:

(1) The instantaneous or interval-average flow rate, in L/min.

(2) The value of the average sample flow rate for the sample period, in L/min.

(3) The value of the coefficient of variation (sample standard deviation divided by the average) of the sample flow rate for the sample period, in percent.

(4) The occurrence of any time interval during the sample period in which the measured sample flow rate exceeds a range of ±5 percent of the average flow rate for the sample period for more than 5 minutes, in which case a warning flag indicator shall be set.

(5) The value of the integrated total sample volume for the sample period, in m^3.

(b) Determination or calculation of these values shall properly exclude periods when the sampler is inoperative due to temporary interruption of electrical power, under section 7.4.13 of this appendix, or flow rate cut off, under section 7.4.4 of this appendix.

(c) These parameters shall be accessible to the sampler operator as specified in Table L–1 of section 7.4.19 of this appendix. In addition, it is strongly encouraged that the flow rate for each 5-minute interval during the sample period be available to the operator following the end of the sample period.

7.4.6 *Leak test capability.*

7.4.6.1 *External leakage.* The sampler shall include an external air leak-test capability consisting of components, accessory hardware, operator interface controls, a written procedure in the associated Operation/Instruction Manual, under section 7.4.18 of this appendix, and all other necessary functional capability to permit and facilitate the sampler operator to conveniently carry out a leak test of the sampler at a field monitoring site without additional equipment. The sampler components to be subjected to this leak test include all components and their interconnections in which external air leakage would or could cause an error in the sampler's measurement of the total volume of sample air that passes through the sample filter.

(a) The suggested technique for the operator to use for this leak test is as follows:

(1) Remove the sampler inlet and installs the flow rate measurement adapter supplied with the sampler, under section 7.3.6 of this appendix.

(2) Close the valve on the flow rate measurement adapter and use the sampler air pump to draw a partial vacuum in the sampler, including (at least) the impactor, filter holder assembly (filter in place), flow measurement device, and interconnections between these devices, of at least 55 mm Hg (75 cm water column), measured at a location downstream of the filter holder assembly.

(3) Plug the flow system downstream of these components to isolate the components under vacuum from the pump, such as with a built-in valve.

(4) Stop the pump.

(5) Measure the trapped vacuum in the sampler with a built-in pressure measuring device.

(6) (i) Measure the vacuum in the sampler with the built-in pressure measuring device again at a later time at least 10 minutes after the first pressure measurement.

(ii) **Caution:** Following completion of the test, the adaptor valve should be opened slowly to limit the flow rate of air into the sampler. Excessive air flow rate may blow oil out of the impactor.

(7) Upon completion of the test, open the adaptor valve, remove the adaptor and plugs, and restore the sampler to the normal operating configuration.

(b) The associated leak test procedure shall require that for successful passage of this test, the difference between the two pressure measurements shall not be greater than the number of mm of Hg specified for the sampler by the manufacturer, based on the actual internal volume of the sampler, that indicates a leak of less than 80 mL/min.

(c) Variations of the suggested technique or an alternative external leak test technique may be required for samplers whose design or configuration would make the suggested technique impossible or impractical. The specific proposed external leak test procedure, or particularly an alternative leak test technique, proposed for a particular candidate sampler may be described and submitted to the EPA for specific individual acceptability either as part of a reference or equivalent method application under part 53 of this chapter or in writing in advance of such an intended application under part 53 of this chapter.

7.4.6.2 *Internal, filter bypass leakage.* The sampler shall include an internal, filter bypass leak-check capability consisting of components, accessory hardware, operator interface controls, a written procedure in the Operation/Instruction Manual, and all other necessary functional capability to permit and facilitate the sampler operator to conveniently carry out a test for internal filter bypass leakage in the sampler at a field monitoring site without additional equipment. The purpose of the test is to determine that any portion of the sample flow rate that leaks past the sample filter without passing through the filter is insignificant relative to the design flow rate for the sampler.

(a) The suggested technique for the operator to use for this leak test is as follows:

(1) Carry out an external leak test as provided under section 7.4.6.1 of this appendix which indicates successful passage of the prescribed external leak test.

(2) Install a flow-impervious membrane material in the filter cassette, either with or without a filter, as appropriate, which effectively prevents air flow through the filter.

(3) Use the sampler air pump to draw a partial vacuum in the sampler, downstream of the filter holder assembly, of at least 55 mm Hg (75 cm water column).

(4) Plug the flow system downstream of the filter holder to isolate the components under vacuum from the pump, such as with a built-in valve.

(5) Stop the pump.

(6) Measure the trapped vacuum in the sampler with a built-in pressure measuring device.

(7) Measure the vacuum in the sampler with the built-in pressure measuring device again at a later time at least 10 minutes after the first pressure measurement.

(8) Remove the flow plug and membrane and restore the sampler to the normal operating configuration.

(b) The associated leak test procedure shall require that for successful passage of this test, the difference between the two pressure measurements shall not be greater than the number of mm of Hg specified for the sampler by the manufacturer, based on the actual internal volume of the portion of the sampler under vacuum, that indicates a leak of less than 80 mL/min.

(c) Variations of the suggested technique or an alternative internal, filter bypass leak test technique may be required for samplers whose design or configuration would make the suggested technique impossible or impractical. The specific proposed internal leak test procedure, or particularly an alternative internal leak test technique proposed for a particular candidate sampler may be described and submitted to the EPA for specific individual acceptability either as part of a reference or equivalent method application under part 53 of this chapter or in writing in advance of such intended application under part 53 of this chapter.

7.4.7 *Range of operational conditions.* The sampler is required to operate properly and meet all requirements specified in this appendix over the following operational ranges.

7.4.7.1 *Ambient temperature.* -30 to +45 °C (Note: Although for practical reasons, the temperature range over which samplers are required to be tested under part 53 of this chapter is -20 to +40 °C, the sampler shall be designed to operate properly over this wider temperature range.).

7.4.7.2 *Ambient relative humidity.* 0 to 100 percent.

7.4.7.3 *Barometric pressure range.* 600 to 800 mm Hg.

7.4.8 *Ambient temperature sensor.* The sampler shall have capability to measure the temperature of the ambient air surrounding the sampler over the range of -30 to +45 °C, with a resolution of 0.1 °C and accuracy of ±2.0 °C, referenced as described in reference 3 in section 13.0 of this appendix, with and without maximum solar insolation.

7.4.8.1 The ambient temperature sensor shall be mounted external to the sampler enclosure and shall have a passive, naturally ventilated sun shield. The sensor shall be located such that the entire sun shield is at least 5 cm above the horizontal plane of the sampler case or enclosure (disregarding the inlet and downtube) and external to the vertical plane of the nearest side or protuberance of the sampler case or enclosure. The maximum temperature measurement error of the ambient temperature measurement system shall be less than 1.6 °C at 1 m/s wind speed and 1000 W/m2 solar radiation intensity.

7.4.8.2 The ambient temperature sensor shall be of such a design and mounted in such a way as to facilitate its convenient dismounting and immersion in a liquid for calibration and comparison to the filter temperature sensor, under section 7.4.11 of this appendix.

7.4.8.3 This ambient temperature measurement shall be updated at least every 30 seconds during both sampling and standby (non-sampling) modes of operation. A visual indication of the current (most recent) value of the ambient temperature measurement, updated at least every 30 seconds, shall be available to the sampler operator during both sampling and standby (non-sampling) modes of operation, as specified in Table L–1 of section 7.4.19 of this appendix.

7.4.8.4 This ambient temperature measurement shall be used for the purpose of monitoring filter temperature deviation from ambient temperature, as required by section 7.4.11 of this appendix, and may be used for purposes of effecting filter temperature control, under section 7.4.10 of this appendix, or computation of volumetric flow rate, under sections 7.4.1 to 7.4.5 of this appendix, if appropriate.

7.4.8.5 Following the end of each sample period, the sampler shall report the maximum, minimum, and average temperature for the sample period, as specified in Table L–1 of section 7.4.19 of this appendix.

7.4.9 *Ambient barometric sensor.* The sampler shall have capability to measure the barometric pressure of the air surrounding the sampler over a range of 600 to 800 mm Hg referenced as described in reference 3 in section 13.0 of this appendix; also see part 53, subpart E of this chapter. This barometric pressure measurement shall have a resolution of 5 mm Hg and an accuracy of ±10 mm Hg and shall be updated at least every 30 seconds. A visual indication of the value of the current (most recent) barometric pressure measurement, updated at least every 30 seconds, shall be available to the sampler operator during both sampling and standby (non-sampling) modes of operation, as specified in Table L–1 of section 7.4.19 of this appendix. This barometric pressure measurement may be used for purposes of computation of volumetric flow rate, under sections 7.4.1 to 7.4.5 of this appendix, if appropriate. Following the end of a sample period, the sampler shall report the maximum, minimum, and mean barometric pressures for the sample period, as specified in Table L–1 of section 7.4.19 of this appendix.

7.4.10 *Filter temperature control (sampling and post-sampling).* The sampler shall provide a means to limit the temperature rise of the sample filter (all sample filters for sequential samplers), from insolation and other sources, to no more 5 °C above the temperature of the ambient air surrounding the sampler, during both sampling and post-sampling periods of operation. The post-sampling period is the non-sampling period between the end of the active sampling period and the time of retrieval of the sample filter by the sampler operator.

7.4.11 *Filter temperature sensor(s).*

7.4.11.1 The sampler shall have the capability to monitor the temperature of the sample filter (all sample filters for sequential samplers) over the range of -30 to +45 °C during both sampling and non-sampling periods. While the exact location of this temperature sensor is not explicitly specified, the filter temperature measurement system must demonstrate agreement, within 1 °C, with a test temperature sensor located within 1 cm of the center of the filter downstream of the filter during both sampling and non-sampling modes, as specified in the filter temperature measurement test described in part 53, subpart E of this chapter. This filter temperature measurement shall have a resolution of 0.1 °C and accuracy of ±1.0 °C, referenced as described in reference 3 in section 13.0 of this appendix. This temperature sensor shall be of such a design and mounted in such a way as to facilitate its reasonably convenient dismounting and immersion in a liquid for calibration and comparison to the ambient temperature sensor under section 7.4.8 of this appendix.

7.4.11.2 The filter temperature measurement shall be updated at least every 30 seconds during both sampling and standby (non-sampling) modes of operation. A visual indication of the current (most recent) value of the filter temperature measurement, updated at least every 30 seconds, shall be available to the sampler operator during both sampling and standby (non-sampling) modes of operation, as specified in Table L–1 of section 7.4.19 of this appendix.

7.4.11.3 For sequential samplers, the temperature of each filter shall be measured individually unless it can be shown, as specified in the filter temperature measurement test described in § 53.57 of this chapter, that the temperature of each filter can be represented by fewer temperature sensors.

7.4.11.4 The sampler shall also provide a warning flag indicator following any occurrence in which the filter temperature (any filter temperature for sequential samplers) exceeds the ambient temperature by more than 5 °C for more than 30 consecutive minutes during either the sampling or post-sampling periods of operation, as specified in Table L–1 of section 7.4.19 of this appendix, under section 10.12 of this appendix, regarding sample validity when a warning flag occurs. It is further recommended (not required) that the sampler be capable of recording the maximum differential between the measured filter temperature and the ambient temperature and its time and date of occurrence during both sampling and post-sampling (non-sampling) modes of operation and providing for those data to be accessible to the sampler operator following the end of the sample period, as suggested in Table L–1 of section 7.4.19 of this appendix.

7.4.12 *Clock/timer system.*

(a) The sampler shall have a programmable real-time clock timing/control system that:

(1) Is capable of maintaining local time and date, including year, month, day-of-month, hour, minute, and second to an accuracy of ±1.0 minute per month.

(2) Provides a visual indication of the current system time, including year, month, day-of-month, hour, and minute, updated at least each minute, for operator verification.

(3) Provides appropriate operator controls for setting the correct local time and date.

(4) Is capable of starting the sample collection period and sample air flow at a specific, operator-settable time and date, and stopping the sample air flow and terminating the sampler collection period 24 hours (1440 minutes) later, or at a specific, operator-settable time and date.

(b) These start and stop times shall be readily settable by the sampler operator to within ±1.0 minute. The system shall provide a visual indication of the current start and stop time settings, readable to ±1.0 minute, for verification by the operator, and the start and stop times shall also be available via the data output port, as specified in Table L–1 of section 7.4.19 of this appendix. Upon execution of a programmed sample period start, the sampler shall automatically reset all sample period information and warning flag indications pertaining to a previous sample period. Refer also to section 7.4.15.4 of this appendix regarding retention of current date and time and programmed start and stop times during a temporary electrical power interruption.

7.4.13 *Sample time determination.* The sampler shall be capable of determining the elapsed sample collection time for each $PM_{2.5}$ sample, accurate to within ±1.0 minute, measured as the time between the start of the sampling period, under section 7.4.12 of this appendix and the termination of the sample period, under section 7.4.12 of this appendix or section 7.4.4 of this appendix. This elapsed sample time shall not include periods when the sampler is inoperative due to a temporary interruption of electrical power, under section 7.4.15.4 of this appendix. In the event that the elapsed sample time determined for the sample period is not within the range specified for the required sample period in section 3.3 of this appendix, the sampler shall set a warning flag indicator. The date and time of the start of the sample period, the value of the elapsed sample time for the sample period, and the flag indicator status shall be available to the sampler operator following the end of the sample period, as specified in Table L–1 of section 7.4.19 of this appendix.

7.4.14 *Outdoor environmental enclosure.* The sampler shall have an outdoor enclosure (or enclosures) suitable to protect the filter and other non-weatherproof components of the sampler from precipitation, wind, dust, extremes of temperature and humidity; to help maintain temperature control of the

filter (or filters, for sequential samplers); and to provide reasonable security for sampler components and settings.

7.4.15 *Electrical power supply.*

7.4.15.1 The sampler shall be operable and function as specified herein when operated on an electrical power supply voltage of 105 to 125 volts AC (RMS) at a frequency of 59 to 61 Hz. Optional operation as specified at additional power supply voltages and/or frequencies shall not be precluded by this requirement.

7.4.15.2 The design and construction of the sampler shall comply with all applicable National Electrical Code and Underwriters Laboratories electrical safety requirements.

7.4.15.3 The design of all electrical and electronic controls shall be such as to provide reasonable resistance to interference or malfunction from ordinary or typical levels of stray electromagnetic fields (EMF) as may be found at various monitoring sites and from typical levels of electrical transients or electronic noise as may often or occasionally be present on various electrical power lines.

7.4.15.4 In the event of temporary loss of electrical supply power to the sampler, the sampler shall not be required to sample or provide other specified functions during such loss of power, except that the internal clock/timer system shall maintain its local time and date setting within ±1 minute per week, and the sampler shall retain all other time and programmable settings and all data required to be available to the sampler operator following each sample period for at least 7 days without electrical supply power. When electrical power is absent at the operator-set time for starting a sample period or is interrupted during a sample period, the sampler shall automatically start or resume sampling when electrical power is restored, if such restoration of power occurs before the operator-set stop time for the sample period.

7.4.15.5 The sampler shall have the capability to record and retain a record of the year, month, day-of-month, hour, and minute of the start of each power interruption of more than 1 minute duration, up to 10 such power interruptions per sample period. (More than 10 such power interruptions shall invalidate the sample, except where an exceedance is measured, under section 3.3 of this appendix.) The sampler shall provide for these power interruption data to be available to the sampler operator following the end of the sample period, as specified in Table L–1 of section 7.4.19 of this appendix.

7.4.16 *Control devices and operator interface.* The sampler shall have mechanical, electrical, or electronic controls, control devices, electrical or electronic circuits as necessary to provide the timing, flow rate measurement and control, temperature control, data storage and computation, operator interface, and other functions specified. Operator-accessible controls, data displays, and interface devices shall be designed to be simple, straightforward, reliable, and easy to learn, read, and operate under field conditions. The sampler shall have provision for operator input and storage of up to 64 characters of numeric (or alphanumeric) data for purposes of site, sampler, and sample identification. This information shall be available to the sampler operator for verification and change and for output via the data output port along with other data following the end of a sample period, as specified in Table L–1 of section 7.4.19 of this appendix. All data required to be available to the operator following a sample collection period or obtained during standby mode in a post-sampling period shall be retained by the sampler until reset, either manually by the operator or automatically by the sampler upon initiation of a new sample collection period.

7.4.17 *Data output port requirement.* The sampler shall have a standard RS–232C data output connection through which digital data may be exported to an external data storage or transmission device. All information which is required to be available at the end of each sample period shall be accessible through this data output connection. The information that shall be accessible though this output port is summarized in Table L–1 of section 7.4.19 of this appendix. Since no specific format for the output data is provided, the sampler manufacturer or vendor shall make available to sampler purchasers appropriate computer software capable of receiving exported sampler data and correctly translating the data into a standard spreadsheet format and optionally any other formats as may be useful to sampler users. This requirement shall not preclude the sampler from offering other types of output connections in addition to the required RS–232C port.

7.4.18 *Operation/instruction manual.* The sampler shall include an associated comprehensive operation or instruction manual, as required by part 53 of this chapter, which includes detailed operating instructions on the setup, operation, calibration, and maintenance of the sampler. This manual shall provide complete and detailed descriptions of the operational and calibration procedures prescribed for field use of the sampler and all instruments utilized as part of this reference method. The manual shall include adequate warning of potential safety hazards that may result from normal use or malfunction of the method and a description of necessary safety precautions. The manual shall also include a clear description of all procedures pertaining to installation, operation, periodic and corrective maintenance, and troubleshooting, and shall include parts identification diagrams.

7.4.19 *Data reporting requirements.* The various information that the sampler is required to provide and how it is to be provided is summarized in the following Table L–1.

TABLE L–1.—SUMMARY OF INFORMATION TO BE PROVIDED BY THE SAMPLER

Information to be provided	Appendix L section reference	Availability				Format

✔ Provision of this information is required.

Provision of this information is optional. If information related to the entire sample period is optionally provided prior to the end of the sample period, the value provided should be the value calculated for the portion of the sampler period completed up to the time the information is provided.

■ Indicates that this information is also required to be provided to the AIRS data bank; see §§58.26 and 58.35 of this chapter.

[1] Information is required to be available to the operator at any time the sampler is operating, whether sampling or not.

[2] Information relates to the entire sampler period and must be provided following the end of the sample period until reset manually by the operator or automatically by the sampler upon the start of a new sample period.

[3] Information shall be available to the operator visually.

[4] Information is to be available as digital data at the sampler's data output port specified in section 7.4.16 of this appendix following the end of the sample period until reset manually by the operator or automatically by the sampler upon the start of a new sample period.

[5] Digital readings, both visual and data output, shall have not less than the number of significant digits and resolution specified.

[6] Flag warnings may be displayed to the operator by a single-flag indicator or each flag may be displayed individually. Only a set (on) flag warning must be indicated; an off (unset) flag may be indicated by the absence of a flag warning. Sampler users should refer to section 10.12 of this appendix regarding the validity of samples for which the sampler provided an associated flag warning.

8.0 *Filter Weighing.* See reference 2 in section 13.0 of this appendix, for additional, more detailed guidance.

8.1 *Analytical balance.* The analytical balance used to weigh filters must be suitable for weighing the type and size of filters specified, under section 6.0 of this appendix, and have a readability of ±1 µg. The balance shall be calibrated as specified by the manufacturer at installation and recalibrated immediately prior to each weighing session. See reference 2 in section 13.0 of this appendix for additional guidance.

8.2 *Filter conditioning.* All sample filters used shall be conditioned immediately before both the pre- and post-sampling weighings as specified below. See reference 2 in section 13.0 of this appendix for additional guidance.

8.2.1 *Mean temperature.* 20 - 23 °C.

8.2.2 *Temperature control.* ±2 °C over 24 hours.

8.2.3 *Mean humidity.* Generally, 30–40 percent relative humidity; however, where it can be shown that the mean ambient relative humidity during sampling is less than 30 percent, conditioning is permissible at a mean relative humidity within ±5 relative humidity percent of the mean ambient relative humidity during sampling, but not less than 20 percent.

8.2.4 *Humidity control.* ±5 relative humidity percent over 24 hours.

8.2.5 *Conditioning time.* Not less than 24 hours.

8.3 *Weighing procedure.*

8.3.1 New filters should be placed in the conditioning environment immediately upon arrival and stored there until the pre-sampling weighing. See reference 2 in section 13.0 of this appendix for additional guidance.

8.3.2 The analytical balance shall be located in the same controlled environment in which the filters are conditioned. The filters shall be weighed immediately following the conditioning period without intermediate or transient exposure to other conditions or environments.

8.3.3 Filters must be conditioned at the same conditions (humidity within ±5 relative humidity percent) before both the pre- and post-sampling weighings.

8.3.4 Both the pre- and post-sampling weighings should be carried out on the same analytical balance, using an effective technique to neutralize static charges on the filter, under reference 2 in section 13.0 of this appendix. If possible, both weighings should be carried out by the same analyst.

8.3.5 The pre-sampling (tare) weighing shall be within 30 days of the sampling period.

8.3.6 The post-sampling conditioning and weighing shall be completed within 240 hours (10 days) after the end of the sample period, unless the filter sample is maintained at 4 °C or less during the entire time between retrieval from the sampler and the start of the conditioning, in which case the period shall

not exceed 30 days. Reference 2 in section 13.0 of this appendix has additional guidance on transport of cooled filters.

8.3.7 Filter blanks.

8.3.7.1 New field blank filters shall be weighed along with the pre-sampling (tare) weighing of each lot of $PM_{2.5}$ filters. These blank filters shall be transported to the sampling site, installed in the sampler, retrieved from the sampler without sampling, and reweighed as a quality control check.

8.3.7.2 New laboratory blank filters shall be weighed along with the pre-sampling (tare) weighing of each set of $PM_{2.5}$ filters. These laboratory blank filters should remain in the laboratory in protective containers during the field sampling and should be reweighed as a quality control check.

8.3.8 Additional guidance for proper filter weighing and related quality assurance activities is provided in reference 2 in section 13.0 of this appendix.

9.0 *Calibration*. Reference 2 in section 13.0 of this appendix contains additional guidance.

9.1 *General requirements.*

9.1.1 Multipoint calibration and single-point verification of the sampler's flow rate measurement device must be performed periodically to establish and maintain traceability of subsequent flow measurements to a flow rate standard.

9.1.2 An authoritative flow rate standard shall be used for calibrating or verifying the sampler's flow rate measurement device with an accuracy of ±2 percent. The flow rate standard shall be a separate, stand-alone device designed to connect to the flow rate measurement adapter, Figure L–30 of this appendix. This flow rate standard must have its own certification and be traceable to a National Institute of Standards and Technology (NIST) primary standard for volume or flow rate. If adjustments to the sampler's flow rate measurement system calibration are to be made in conjunction with an audit of the sampler's flow measurement system, such adjustments shall be made following the audit. Reference 2 in section 13.0 of this appendix contains additional guidance.

9.1.3 The sampler's flow rate measurement device shall be re-calibrated after electromechanical maintenance or transport of the sampler.

9.2 *Flow rate calibration/verification procedure.*

9.2.1 $PM_{2.5}$ samplers may employ various types of flow control and flow measurement devices. The specific procedure used for calibration or verification of the flow rate measurement device will vary depending on the type of flow rate controller and flow rate measurement employed. Calibration shall be in terms of actual ambient volumetric flow rates (Q^a), measured at the sampler's inlet downtube. The generic procedure given here serves to illustrate the general steps involved in the calibration of a $PM_{2.5}$ sampler. The sampler operation/instruction manual required under section 7.4.18 of this appendix and the Quality Assurance Handbook in reference 2 in section 13.0 of this appendix provide more specific and detailed guidance for calibration.

9.2.2 The flow rate standard used for flow rate calibration shall have its own certification and be traceable to a NIST primary standard for volume or flow rate. A calibration relationship for the flow rate standard, e.g., an equation, curve, or family of curves relating actual flow rate (Q_a) to the flow rate indicator reading, shall be established that is accurate to within 2 percent over the expected range of ambient temperatures and pressures at which the flow rate standard may be used. The flow rate standard must be re-calibrated or re-verified at least annually.

9.2.3 The sampler flow rate measurement device shall be calibrated or verified by removing the sampler inlet and connecting the flow rate standard to the sampler's downtube in accordance with the operation/instruction manual, such that the flow rate standard accurately measures the sampler's flow rate. The sampler operator shall first carry out a sampler leak check and confirm that the sampler passes the leak test and then verify that no leaks exist between the flow rate standard and the sampler.

9.2.4 The calibration relationship between the flow rate (in actual L/min) indicated by the flow rate standard and by the sampler's flow rate measurement device shall be established or verified in accordance with the sampler operation/instruction manual. Temperature and pressure corrections to the flow rate indicated by the flow rate standard may be required for certain types of flow rate standards. Calibration of the sampler's flow rate measurement device shall consist of at least three separate flow rate measurements (multipoint calibration) evenly spaced within the range of -10 percent to +10 percent of the sampler's operational flow rate, section 7.4.1 of this appendix. Verification of the sampler's flow rate shall consist of one flow rate measurement at the sampler's operational flow rate. The sampler operation/instruction manual and reference 2 in section 13.0 of this appendix provide additional guidance.

9.2.5 If during a flow rate verification the reading of the sampler's flow rate indicator or measurement device differs by ±2 percent or more from the flow rate measured by the flow rate standard, a new multipoint calibration shall be performed and the flow rate verification must then be repeated.

9.2.6 Following the calibration or verification, the flow rate standard shall be removed from the sampler and the sampler inlet shall be reinstalled. Then the sampler's normal operating flow rate (in L/min) shall be determined with a clean filter in place. If the flow rate indicated by the sampler differs by ±2 percent or more from the required sampler flow rate, the sampler flow rate must be adjusted to the required flow rate, under section 7.4.1 of this appendix.

9.3 Periodic calibration or verification of the calibration of the sampler's ambient temperature, filter temperature, and barometric pressure measurement systems is also required. Reference 3 of section 13.0 of this appendix contains additional guidance.

10.0 *$PM_{2.5}$ Measurement Procedure* The detailed procedure for obtaining valid $PM_{2.5}$ measurements with each specific sampler designated as part of a reference method for $PM_{2.5}$ under part 53 of this chapter shall be provided in the sampler-specific operation or instruction manual required by section 7.4.18 of this appendix. Supplemental guidance is provided in section 2.12 of the Quality Assurance Handbook listed in reference 2 in section 13.0 of this appendix. The generic procedure given here serves to illustrate the general steps involved in the $PM_{2.5}$ sample collection and measurement, using a $PM_{2.5}$ reference method sampler.

10.1 The sampler shall be set up, calibrated, and operated in accordance with the specific, detailed guidance provided in the specific sampler's operation or instruction manual and in accordance with a specific quality assurance program developed and established by the user, based on applicable supplementary guidance provided in reference 2 in section 13.0 of this appendix.

10.2 Each new sample filter shall be inspected for correct type and size and for pinholes, particles, and other imperfections. Unacceptable filters should be discarded. A unique identification number shall be assigned to each filter, and an information record shall be established for each filter. If the filter identification number is not or cannot be marked directly on the filter, alternative means, such as a number-identified storage container, must be established to maintain positive filter identification.

10.3 Each filter shall be conditioned in the conditioning environment in accordance with the requirements specified in section 8.2 of this appendix.

10.4 Following conditioning, each filter shall be weighed in accordance with the requirements specified in section 8.0 of this appendix and the presampling weight recorded with the filter identification number.

10.5 A numbered and preweighed filter shall be installed in the sampler following the instructions provided in the sampler operation or instruction manual.

10.6 The sampler shall be checked and prepared for sample collection in accordance with instructions provided in the sampler operation or instruction manual and with the specific quality assurance program established for the sampler by the user.

10.7 The sampler's timer shall be set to start the sample collection at the beginning of the desired sample period and stop the sample collection 24 hours later.

10.8 Information related to the sample collection (site location or identification number, sample date, filter identification number, and sampler model and serial number) shall be recorded and, if appropriate, entered into the sampler.

10.9 The sampler shall be allowed to collect the $PM_{2.5}$ sample during the set 24-hour time period.

10.10 Within 96 hours of the end of the sample collection period, the filter, while still contained in the filter cassette, shall be carefully removed from the sampler, following the procedure provided in the sampler operation or instruction manual and the quality assurance program, and placed in a protective container. This protective container shall be made of metal and contain no loose material that could be transferred to the filter. The protective container shall hold

the filter cassette securely such that the cover shall not come in contact with the filter's surfaces. Reference 2 in section 13.0 of this appendix contains additional information.

10.11 The total sample volume in actual m^3 for the sampling period and the elapsed sample time shall be obtained from the sampler and recorded in accordance with the instructions provided in the sampler operation or instruction manual. All sampler warning flag indications and other information required by the local quality assurance program shall also be recorded.

10.12 All factors related to the validity or representativeness of the sample, such as sampler tampering or malfunctions, unusual meteorological conditions, construction activity, fires or dust storms, etc. shall be recorded as required by the local quality assurance program. The occurrence of a flag warning during a sample period shall not necessarily indicate an invalid sample but rather shall indicate the need for specific review of the QC data by a quality assurance officer to determine sample validity.

10.13 After retrieval from the sampler, the exposed filter containing the $PM_{2.5}$ sample should be transported to the filter conditioning environment as soon as possible ideally to arrive at the conditioning environment within 24 hours for conditioning and subsequent weighing. During the period between filter retrieval from the sampler and the start of the conditioning, the filter shall be maintained as cool as practical and continuously protected from exposure to temperatures over 25 °C. See section 8.3.6 of this appendix regarding time limits for completing the post-sampling weighing. See reference 2 in section 13.0 of this appendix for additional guidance on transporting filter samplers to the conditioning and weighing laboratory.

10.14. The exposed filter containing the $PM_{2.5}$ sample shall be re-conditioned in the conditioning environment in accordance with the requirements specified in section 8.2 of this appendix.

10.15. The filter shall be reweighed immediately after conditioning in accordance with the requirements specified in section 8.0 of this appendix, and the postsampling weight shall be recorded with the filter identification number.

10.16 The $PM_{2.5}$ concentration shall be calculated as specified in section 12.0 of this appendix.

11.0 *Sampler Maintenance*

The sampler shall be maintained as described by the sampler's manufacturer in the sampler-specific operation or instruction manual required under section 7.4.18 of this appendix and in accordance with the specific quality assurance program developed and established by the user based on applicable supplementary guidance provided in reference 2 in section 13.0 of this appendix.

12.0 *Calculations*

12.1 (a) The $PM_{2.5}$ concentration is calculated as:

$$PM_{2.5} = (W_f - W_i)/V_a$$

where:

$PM_{2.5}$ = mass concentration of $PM_{2.5}$, $\mu g/m^3$;

W_f, W_i = final and initial weights, respectively, of the filter used to collect the $PM_{2.5}$ particle sample, μg;

V_a = total air volume sampled in actual volume units, as provided by the sampler, m^3.

(b) Note: Total sample time must be between 1,380 and 1,500 minutes (23 and 25 hrs) for a fully valid $PM_{2.5}$ sample; however, see also section 3.3 of this appendix.

7. Appendix M is added to read as follows:

Appendix M to Part 50—Reference Method for the Determination of Particulate Matter as PM_{10} in the Atmosphere

1.0 *Applicability.*

1.1 This method provides for the measurement of the mass concentration of particulate matter with an aerodynamic diameter less than or equal to a nominal 10 micrometers (PM_{10}) in ambient air over a 24-hour period for purposes of determining attainment and maintenance of the primary and secondary national ambient air quality standards for particulate matter specified in § 50.6 of this chapter. The measurement process is nondestructive, and the PM_{10} sample can be subjected to subsequent physical or chemical analyses. Quality assurance procedures and guidance are provided in part 58, Appendices A and B of this chapter and in references 1 and 2 of section 12.0 of this appendix.

2.0 *Principle.*

2.1 An air sampler draws ambient air at a constant flow rate into a specially shaped inlet where the suspended particulate matter is inertially separated into one or more size fractions within the PM_{10} size range. Each size fraction in the PM_{10} size range is then collected on a separate filter over the specified sampling period. The particle size discrimination characteristics (sampling effectiveness and 50 percent cutpoint) of the sampler inlet are prescribed as performance specifications in part 53 of this chapter.

2.2 Each filter is weighed (after moisture equilibration) before and after use to determine the net weight (mass) gain due to collected PM_{10}. The total volume of air sampled, measured at the actual ambient temperature and pressure, is determined from the measured flow rate and the sampling time. The mass concentration of PM_{10} in the ambient air is computed as the total mass of collected particles in the PM_{10} size range divided by the volume of air sampled, and is expressed in micrograms per actual cubic meter ($\mu g/m^3$).

2.3 A method based on this principle will be considered a reference method only if the associated sampler meets the requirements specified in this appendix and the requirements in part 53 of this chapter, and the method has been designated as a reference method in accordance with part 53 of this chapter.

3.0 *Range.*

3.1 The lower limit of the mass concentration range is determined by the repeatability of filter tare weights, assuming the nominal air sample volume for the sampler. For samplers having an automatic filter-changing mechanism, there may be no upper limit. For samplers that do not have an automatic filter-changing mechanism, the upper limit is determined by the filter mass loading beyond which the sampler no longer maintains the operating flow rate within specified limits due to increased pressure drop across the loaded filter. This upper limit cannot be specified precisely because it is a complex function of the ambient particle size distribution and type, humidity, filter type, and perhaps other factors. Nevertheless, all samplers should be capable of measuring 24-hour PM_{10} mass concentrations of at least 300 $\mu g/m^3$ while maintaining the operating flow rate within the specified limits.

4.0 *Precision.*

4.1 The precision of PM_{10} samplers must be 5 $\mu g/m^3$ for PM_{10} concentrations below 80 $\mu g/m^3$ and 7 percent for PM_{10} concentrations above 80 $\mu g/m^3$, as required by part 53 of this chapter, which prescribes a test procedure that determines the variation in the PM_{10} concentration measurements of identical samplers under typical sampling conditions. Continual assessment of precision via collocated samplers is required by part 58 of this chapter for PM_{10} samplers used in certain monitoring networks.

5.0 *Accuracy.*

5.1 Because the size of the particles making up ambient particulate matter varies over a wide range and the concentration of particles varies with particle size, it is difficult to define the absolute accuracy of PM_{10} samplers. Part 53 of this chapter provides a specification for the sampling effectiveness of PM_{10} samplers. This specification requires that the expected mass concentration calculated for a candidate PM_{10} sampler, when sampling a specified particle size distribution, be within ±10 percent of that calculated for an ideal sampler whose sampling effectiveness is explicitly specified. Also, the particle size for 50 percent sampling effectiveness is required to be 10±0.5 micrometers. Other specifications related to accuracy apply to flow measurement and calibration, filter media, analytical (weighing) procedures, and artifact. The flow rate accuracy of PM_{10} samplers used in certain monitoring networks is required by part 58 of this chapter to be assessed periodically via flow rate audits.

6.0 *Potential Sources of Error.*

6.1 *Volatile Particles.* Volatile particles collected on filters are often lost during shipment and/or storage of the filters prior to the post-sampling weighing [3]. Although shipment or storage of loaded filters is sometimes unavoidable, filters should be reweighed as soon as practical to minimize these losses.

6.2 *Artifacts.* Positive errors in PM_{10} concentration measurements may result from retention of gaseous species on filters [4, 5]. Such errors include the retention of sulfur dioxide and nitric acid. Retention of sulfur dioxide on filters, followed by oxidation to sulfate, is referred to as artifact sulfate formation, a phenomenon which increases with increasing filter alkalinity [6]. Little or no artifact sulfate formation should occur using filters that meet the alkalinity specification in section 7.2.4 of this appendix, Artifact nitrate formation, resulting primarily from retention of nitric acid, occurs to varying degrees on many filter types, including glass fiber, cellulose ester, and many quartz fiber filters [5, 7, 8, 9, 10]. Loss of true atmospheric particulate nitrate during or following sampling may also occur due to dissociation or chemical reaction. This phenomenon has been observed on Teflon® filters [8] and inferred for quartz fiber filters [11, 12]. The magnitude of nitrate artifact errors in PM_{10} mass concentration measurements will vary with location and ambient temperature; however, for most sampling locations, these errors are expected to be small.

6.3 *Humidity.* The effects of ambient humidity on the sample are unavoidable. The filter equilibration procedure in section 9.0 of this appendix is designed to minimize the effects of moisture on the filter medium.

6.4 *Filter Handling.* Careful handling of filters between presampling and postsampling weighings is necessary to avoid errors due to damaged filters or loss of collected particles from the filters. Use of a filter cartridge or cassette may reduce the magnitude of these errors. Filters must also meet the integrity specification in section 7.2.3 of this appendix.

6.5 *Flow Rate Variation.* Variations in the sampler's operating flow rate may alter the particle size discrimination characteristics of the sampler inlet. The magnitude of this error will depend on the sensitivity of the inlet to variations in flow rate and on the particle distribution in the atmosphere during the sampling period. The use of a flow control device, under section 7.1.3 of this appendix, is required to minimize this error.

6.6 *Air Volume Determination.* Errors in the air volume determination may result from errors in the flow rate and/or sampling time measurements. The flow control device serves to minimize errors in the flow rate determination, and an elapsed time meter, under section 7.1.5 of this appendix, is required to minimize the error in the sampling time measurement.

7.0 *Apparatus.*

7.1 PM_{10} Sampler.

7.1.1 The sampler shall be designed to:

(a) Draw the air sample into the sampler inlet and through the particle collection filter at a uniform face velocity.

(b) Hold and seal the filter in a horizontal position so that sample air is drawn downward through the filter.

(c) Allow the filter to be installed and removed conveniently.

(d) Protect the filter and sampler from precipitation and prevent insects and other debris from being sampled.

(e) Minimize air leaks that would cause error in the measurement of the air volume passing through the filter.

(f) Discharge exhaust air at a sufficient distance from the sampler inlet to minimize the sampling of exhaust air.

(g) Minimize the collection of dust from the supporting surface.

7.1.2 The sampler shall have a sample air inlet system that, when operated within a specified flow rate range, provides particle size discrimination characteristics meeting all of the applicable performance specifications prescribed in part 53 of this chapter. The sampler inlet shall show no significant wind direction dependence. The latter requirement can generally be satisfied by an inlet shape that is circularly symmetrical about a vertical axis.

7.1.3 The sampler shall have a flow control device capable of maintaining the sampler's operating flow rate within the flow rate limits specified for the sampler inlet over normal variations in line voltage and filter pressure drop.

7.1.4 The sampler shall provide a means to measure the total flow rate during the sampling period. A continuous flow recorder is recommended but not required. The flow measurement device shall be accurate to ±2 percent.

7.1.5 A timing/control device capable of starting and stopping the sampler shall be used to obtain a sample collection period of 24 ±1 hr (1,440 ±60 min). An elapsed time meter, accurate to within ±15 minutes, shall be used to measure sampling time. This meter is optional for samplers with continuous flow recorders if the sampling time measurement obtained by means of the recorder meets the ±15 minute accuracy specification.

7.1.6 The sampler shall have an associated operation or instruction manual as required by part 53 of this chapter which includes detailed instructions on the calibration, operation, and maintenance of the sampler.

7.2 *Filters.*

7.2.1 *Filter Medium.* No commercially available filter medium is ideal in all respects for all samplers. The user's goals in sampling determine the relative importance of various filter characteristics, e.g., cost, ease of handling, physical and chemical characteristics, etc., and, consequently, determine the choice among acceptable filters. Furthermore, certain types of filters may not be suitable for use with some samplers, particularly under heavy loading conditions (high mass concentrations), because of high or rapid increase in the filter flow resistance that would exceed the capability of the sampler's flow control device. However, samplers equipped with automatic filter-changing mechanisms may allow use of these types of filters. The specifications given below are minimum requirements to ensure acceptability of the filter medium for measurement of PM_{10} mass concentrations. Other filter evaluation criteria should be considered to meet individual sampling and analysis objectives.

7.2.2 *Collection Efficiency.* ≥99 percent, as measured by the DOP test (ASTM–2986) with 0.3 µm particles at the sampler's operating face velocity.

7.2.3 *Integrity.* ±5 µg/m^3 (assuming sampler's nominal 24-hour air sample volume). Integrity is measured as the PM_{10} concentration equivalent corresponding to the average difference between the initial and the final weights of a random sample of test filters that are weighed and handled under actual or simulated sampling conditions, but have no air sample passed through them, i.e., filter blanks. As a minimum, the test procedure must include initial equilibration and weighing, installation on an inoperative sampler, removal from the sampler, and final equilibration and weighing.

7.2.4 *Alkalinity.* <25 microequivalents/gram of filter, as measured by the procedure given in reference 13 of section 12.0 of this appendix following at least two months storage in a clean environment (free from contamination by acidic gases) at room temperature and humidity.

7.3 *Flow Rate Transfer Standard.* The flow rate transfer standard must be suitable for the sampler's operating flow rate and must be calibrated against a primary flow or volume standard that is traceable to the National Institute of Standard and Technology (NIST). The flow rate transfer standard must be capable of measuring the sampler's operating flow rate with an accuracy of ±2 percent.

7.4 *Filter Conditioning Environment.*

7.4.1 *Temperature range.* 15 to 30 C.

7.4.2 *Temperature control.* ±3 C.

7.4.3 *Humidity range.* 20% to 45% RH.

7.4.4 *Humidity control.* ±5% RH.

7.5 *Analytical Balance.* The analytical balance must be suitable for weighing the type and size of filters required by the sampler. The range and sensitivity required will depend on the filter tare weights and mass loadings. Typically, an analytical balance with a sensitivity of 0.1 mg is required for high volume samplers (flow rates >0.5 m^3/min). Lower volume samplers (flow rates <0.5 m^3/min) will require a more sensitive balance.

8.0 *Calibration.*

8.1 *General Requirements.*

8.1.1 Calibration of the sampler's flow measurement device is required to establish traceability of subsequent flow measurements to a primary standard. A flow rate transfer standard calibrated against a primary flow or volume standard shall be used to calibrate or verify the accuracy of the sampler's flow measurement device.

8.1.2 Particle size discrimination by inertial separation requires that specific air velocities be maintained in the sampler's air inlet system. Therefore, the flow rate through the sampler's inlet must be maintained throughout the sampling period within the design flow rate range specified by the manufacturer. Design flow rates are specified as actual volumetric flow rates, measured at existing conditions of temperature and pressure (Q_a).

8.2 *Flow Rate Calibration Procedure.*

8.2.1 PM_{10} samplers employ various types of flow control and flow measurement devices. The specific procedure used for flow rate calibration or verification will vary depending on the type of flow controller and flow rate indicator employed. Calibration is in terms of actual volumetric flow rates (Q_a) to meet the requirements of section 8.1 of this appendix. The general procedure given here serves to illustrate the steps involved in the calibration. Consult the sampler manufacturer's instruction manual and reference 2 of section 12.0 of this appendix for specific guidance on calibration. Reference 14 of section 12.0 of this appendix provides additional information on various other measures of flow rate and their interrelationships.

8.2.2 Calibrate the flow rate transfer standard against a primary flow or volume standard traceable to NIST. Establish a calibration relationship, e.g., an equation or family of curves, such that traceability to the primary standard is accurate to within 2 percent over the expected range of ambient conditions, i.e., temperatures and pressures, under which the transfer standard will be used. Recalibrate the transfer standard periodically.

8.2.3 Following the sampler manufacturer's instruction manual, remove the sampler inlet and connect the flow rate transfer standard to the sampler such that the transfer standard accurately measures the sampler's flow rate. Make sure there are no leaks between the transfer standard and the sampler.

8.2.4 Choose a minimum of three flow rates (actual m^3/min), spaced over the acceptable flow rate range specified for the inlet, under section 7.1.2 of the appendix, that can be obtained by suitable adjustment of the sampler flow rate. In accordance with the sampler manufacturer's instruction manual, obtain or verify the calibration relationship between the flow rate (actual m^3/min) as indicated by the transfer standard and the sampler's flow indicator response. Record the ambient temperature and barometric pressure. Temperature and pressure corrections to subsequent flow indicator readings may be required for certain types of flow measurement devices. When such corrections are necessary, correction on an individual or daily basis is preferable. However, seasonal average temperature and average barometric pressure for the sampling site may be incorporated into the sampler calibration to avoid daily corrections. Consult the sampler manufacturer's instruction manual and reference 2 in section 12.0 of this appendix for additional guidance.

8.2.5 Following calibration, verify that the sampler is operating at its design flow rate (actual m^3/min) with a clean filter in place.

8.2.6 Replace the sampler inlet.

9.0 *Procedure.*

9.1 The sampler shall be operated in accordance with the specific guidance provided in the sampler manufacturer's instruction manual and in reference 2 in section 12.0 of this appendix. The general procedure given here assumes that the sampler's flow rate calibration is based on flow rates at ambient conditions (Q_a) and serves to illustrate the steps involved in the operation of a PM_{10} sampler.

9.2 Inspect each filter for pinholes, particles, and other imperfections. Establish a filter information record and assign an identification number to each filter.

9.3 Equilibrate each filter in the conditioning environment (see 7.4) for at least 24 hours.

9.4 Following equilibration, weigh each filter and record the presampling weight with the filter identification number.

9.5 Install a preweighed filter in the sampler following the instructions provided in the sampler manufacturer's instruction manual.

9.6 (a) Turn on the sampler and allow it to establish run-temperature conditions. Record the flow indicator reading and, if needed, the ambient temperature and barometric pressure. Determine the sampler flow rate (actual m^3/min) in accordance with the instructions provided in the sampler manufacturer's instruction manual.

(b) Note: No onsite temperature or pressure measurements are necessary if the sampler's flow indicator does not require temperature or pressure corrections or if seasonal average temperature and average barometric pressure for the sampling site are incorporated into

the sampler calibration, under section 8.2.4 of this appendix. If individual or daily temperature and pressure corrections are required, ambient temperature and barometric pressure can be obtained by on-site measurements or from a nearby weather station. Barometric pressure readings obtained from airports must be station pressure, not corrected to sea level, and may need to be corrected for differences in elevation between the sampling site and the airport.

9.7 If the flow rate is outside the acceptable range specified by the manufacturer, check for leaks, and if necessary, adjust the flow rate to the specified setpoint. Stop the sampler.

9.8 Set the timer to start and stop the sampler at appropriate times. Set the elapsed time meter to zero or record the initial meter reading.

9.9 Record the sample information (site location or identification number, sample date, filter identification number, and sampler model and serial number).

9.10 Sample for 24±1 hours.

9.11 Determine and record the average flow rate (Q_a) in actual m^3/min for the sampling period in accordance with the instructions provided in the sampler manufacturer's instruction manual. Record the elapsed time meter final reading and, if needed, the average ambient temperature and barometric pressure for the sampling period, in note following section 9.6 of this appendix.

9.12 Carefully remove the filter from the sampler, following the sampler manufacturer's instruction manual. Touch only the outer edges of the filter.

9.13 Place the filter in a protective holder or container, e.g., petri dish, glassine envelope, or manila folder.

9.14 Record any factors such as meteorological conditions, construction activity, fires or dust storms, etc., that might be pertinent to the measurement on the filter information record.

9.15 Transport the exposed sample filter to the filter conditioning environment as soon as possible for equilibration and subsequent weighing.

9.16 Equilibrate the exposed filter in the conditioning environment for at least 24 hours under the same temperature and humidity conditions used for presampling filter equilibration (see section 9.3 of this appendix).

9.17 Immediately after equilibration, reweigh the filter and record the postsampling weight with the filter identification number.

10.0 *Sampler Maintenance.*

10.1 The PM_{10} sampler shall be maintained in strict accordance with the maintenance procedures specified in the sampler manufacturer's instruction manual.

11.0 *Calculations.*

11.1 Calculate the total volume of air sampled as:

$$V = Q_a t$$

where:

V = total air sampled, at ambient temperature and pressure, m^3;

Q_a = average sample flow rate at ambient temperature and pressure, m^3/min; and

t = sampling time, min.

11.2 (a) Calculate the PM_{10} concentration as:

$$PM_{10} = (W_f - W_i) \times 10^6 / V$$

where:

PM_{10} = mass concentration of PM_{10}, $\mu g/m^3$;

W_f, W_i = final and initial weights of filter collecting PM_{1O} particles, g; and

10^6 = conversion of g to µg.

(b) Note: If more than one size fraction in the PM_{10} size range is collected by the sampler, the sum of the net weight gain by each collection filter $[\Sigma(W_f - W_i)]$ is used to calculate the PM_{10} mass concentration.

8. Appendix N is added to read as follows:

Appendix N to Part 50—Interpretation of the National Ambient Air Quality Standards for Particulate Matter

1.0 *General.*

(a) This appendix explains the data handling conventions and computations necessary for determining when the annual and 24-hour primary and secondary national ambient air quality standards for PM specified in § 50.7 of this chapter are met. Particulate matter is measured in the ambient air as PM_{10} and $PM_{2.5}$ (particles with an aerodynamic diameter less than or equal to a nominal 10 and 2.5 micrometers, respectively) by a reference method based on Appendix M of this part for PM_{10} and on Appendix L of this part for $PM_{2.5}$, as applicable, and designated in accordance with part 53 of this chapter, or by an equivalent method designated in accordance with part 53 of this chapter. Data handling and computation procedures to be used in making comparisons between reported PM_{10} and $PM_{2.5}$ concentrations and the levels of the PM standards are specified in the following sections.

(b) Data resulting from uncontrollable or natural events, for example structural fires or high winds, may require special consideration. In some cases, it may be appropriate to exclude these data because they could result in inappropriate values to compare with the levels of the PM standards. In other cases, it may be more appropriate to retain the data for comparison with the level of the PM standards and then allow the EPA to formulate the appropriate regulatory response. Whether to exclude, retain, or make adjustments to the data affected by uncontrollable or natural events is subject to the approval of the appropriate Regional Administrator.

(c) The terms used in this appendix are defined as follows:

Average and *mean* refer to an arithmetic mean.

Daily value for PM refers to the 24-hour average concentration of PM calculated or measured from midnight to midnight (local time) for PM_{10} or $PM_{2.5}$.

Designated monitors are those monitoring sites designated in a State PM Monitoring Network Description for spatial averaging in areas opting for spatial averaging in accordance with part 58 of this chapter.

98^{th} *percentile* (used for $PM_{2.5}$) means the daily value out of a year of monitoring data below which 98 percent of all values in the group fall.

99th *percentile* (used for PM_{10}) means the daily value out of a year of monitoring data below which 99 percent of all values in the group fall.

Year refers to a calendar year.

(d) Sections 2.1 and 2.5 of this appendix contain data handling instructions for the option of using a spatially averaged network of monitors for the annual standard. If spatial averaging is not considered for an area, then the spatial average is equivalent to the annual average of a single site and is treated accordingly in subsequent calculations. For example, paragraph (a)(3) of section 2.1 of this appendix could be eliminated since the spatial average would be equivalent to the annual average.

2.0 *Comparisons with the $PM_{2.5}$ Standards.*

2.1 *Annual $PM_{2.5}$ Standard.*

(a) The annual $PM_{2.5}$ standard is met when the 3-year average of the spatially averaged annual means is less than or equal to 15.0 μg/m^3. The 3-year average of the spatially averaged annual means is determined by averaging quarterly means at each monitor to obtain the annual mean $PM_{2.5}$ concentrations at each monitor, then averaging across all designated monitors, and finally averaging for 3 consecutive years. The steps can be summarized as follows:

(1) Average 24-hour measurements to obtain quarterly means at each monitor.

(2) Average quarterly means to obtain annual means at each monitor.

(3) Average across designated monitoring sites to obtain an annual spatial mean for an area (this can be one site in which case the spatial mean is equal to the annual mean).

(4) Average 3 years of annual spatial means to obtain a 3-year average of spatially averaged annual means.

(b) In the case of spatial averaging, 3 years of spatial averages are required to demonstrate that the standard has been met. Designated sites with less than 3 years of data shall be included in spatial averages for those years that data completeness requirements are met. For the annual $PM_{2.5}$ standard, a year meets data completeness requirements when at least 75 percent of the scheduled sampling days for each quarter have valid data. However, years with high concentrations and more than a minimal amount of data (at least 11 samples in each quarter) shall not be ignored just because they are comprised of quarters with less than complete data. Thus, in computing annual spatially averaged means, years containing quarters with at least 11 samples but less than 75 percent data completeness shall be included in the computation if the resulting spatially averaged annual mean concentration (rounded according to the conventions of section 2.3 of this appendix) is greater than the level of the standard.

(c) Situations may arise in which there are compelling reasons to retain years containing quarters which do not meet the data completeness requirement of 75 percent or the minimum number of 11 samples. The use of less than complete data is subject to the approval of the appropriate Regional Administrator.

(d) The equations for calculating the 3-year average annual mean of the $PM_{2.5}$ standard are given in section 2.5 of this appendix.

2.2 *24-Hour $PM_{2.5}$ Standard.*

(a) The 24-hour $PM_{2.5}$ standard is met when the 3-year average of the 98th percentile values at each monitoring site is less than or equal to 65 μg/m^3. This comparison shall be based on 3 consecutive, complete years of air quality data. A year meets data completeness requirements when at least 75 percent of the scheduled sampling days for each quarter have valid data. However, years with high concentrations shall not be ignored just because they are comprised of quarters with less than complete data. Thus, in computing the 3-year average 98th percentile value, years containing quarters with less than 75 percent data completeness shall be included in the computation if the annual 98th percentile value (rounded according to the conventions of section 2.3 of this appendix) is greater than the level of the standard.

(b) Situations may arise in which there are compelling reasons to retain years containing quarters which do not meet the data completeness requirement. The use of less than complete data is subject to the approval of the appropriate Regional Administrator.

(c) The equations for calculating the 3-year average of the annual 98th percentile values is given in section 2.6 of this appendix.

2.3 *Rounding Conventions.* For the purposes of comparing calculated values to the applicable level of the standard, it is necessary to round the final results of the calculations described in sections 2.5 and 2.6 of this appendix. For the annual $PM_{2.5}$ standard, the 3-year average of the spatially averaged annual means shall be rounded to the nearest 0.1 μg/m^3 (decimals 0.05 and greater are rounded up to the next 0.1, and any decimal lower than 0.05 is rounded down to the nearest 0.1). For the 24-hour $PM_{2.5}$ standard, the 3-year average of the annual 98th percentile values shall be rounded to the nearest 1 μg/m^3 (decimals 0.5 and greater are rounded up to nearest whole number, and any decimal lower than 0.5 is rounded down to the nearest whole number).

2.4 *Monitoring Considerations.*

(a) Section 58.13 of this chapter specifies the required minimum frequency of sampling for $PM_{2.5}$. Exceptions to the specified sampling frequencies, such as a reduced frequency during a season of expected low concentrations, are subject to the approval of the appropriate Regional Administrator. Section 58.14 of 40 CFR part 58 and section 2.8 of Appendix D of 40 CFR part 58, specify which monitors are eligible for making comparisons with the PM standards. In determining a spatial mean using two or more monitoring sites operating in a given year, the annual mean for an individual site may be included in the spatial mean if and only if the mean for that site meets the criterion specified in § 2.8 of Appendix D of 40 CFR part 58. In the event data from an otherwise eligible site is excluded from being averaged with data from other sites on the basis of this criterion, then the 3-year mean from that site shall be compared directly to the annual standard.

(b) For the annual $PM_{2.5}$ standard, when designated monitors are located at the same site and are reporting $PM_{2.5}$ values for the same time periods, and when spatial averaging has been chosen, their concentrations shall be averaged before an area-wide spatial average is calculated. Such monitors will then be considered as one monitor.

2.5 *Equations for the Annual $PM_{2.5}$ Standard.*

(a) An annual mean value for $PM_{2.5}$ is determined by first averaging the daily values of a calendar quarter:

Equation 1

$$\bar{x}_{q,y,s} = \frac{1}{n_q}\sum_{i=1}^{n_q} x_{i,q,y,s}$$

where:

$\bar{x}_{q,y,s}$ = the mean for quarter q of year y for site s;

n_q = the number of monitored values in the quarter; and

$x_{i,q,y,s}$ = the i^{th} value in quarter q for year y for site s.

(b) The following equation is then to be used for calculation of the annual mean:

Equation 2

$$\bar{x}_{y,s} = \frac{1}{4}\sum_{q=1}^{4} \bar{x}_{q,y,s}$$

where:

$\bar{x}_{y,s}$ = the annual mean concentration for year y (y = 1, 2, or 3) and for site s; and

$\bar{x}_{q,y,s}$ = the mean for quarter q of year y for site s.

(c) (1) The spatially averaged annual mean for year y is computed by first calculating the annual mean for each site designated to be included in a spatial average, $\bar{x}_{y,s}$, and then computing the average of these values across sites:

Equation 3

$$\bar{x}_{y} = \frac{1}{n_s}\sum_{s=1}^{n_s} \bar{x}_{y,s}$$

where:

$\bar{x}_{y}$ = the spatially averaged mean for year y;

$\bar{x}_{y,s}$ = the annual mean for year y and site s; and

n_s = the number of sites designated to be averaged.

(2) In the event that an area designated for spatial averaging has two or more sites at the same location producing data for the same time periods, the sites are averaged together before using Equation 3 by:

Equation 4

$$\bar{x}_{y,s*} = \frac{1}{n_c}\sum_{s=1}^{n_c} \bar{x}_{y,s}$$

where:

$\bar{x}_{y,s*}$ = the annual mean for year y for the sites at the same location (which will now be considered one site);

n_c = the number of sites at the same location designated to be included in the spatial average; and

$\bar{x}_{y,s}$ = the annual mean for year y and site s.

(d) The 3-year average of the spatially averaged annual means is calculated by using the following equation:

Equation 5

$$\bar{x} = \frac{1}{3}\sum_{y=1}^{3} \bar{x}_y$$

where:

$\bar{x}$ = the 3-year average of the spatially averaged annual means; and

$\bar{x}_y$ = the spatially averaged annual mean for year y.

Example 1—Area Designated for Spatial Averaging That Meets the Primary Annual $PM_{2.5}$ Standard.

a. In an area designated for spatial averaging, four designated monitors recorded data in at least 1 year of a particular 3-year period. Using Equations 1 and 2, the annual means for $PM_{2.5}$ at each site are calculated for each year. The following table can be created from the results. Data completeness percentages for the quarter with the fewest number of samples are also shown.

Table 1.—Results from Equations 1 and 2

		Site #1	Site #2	Site #3	Site #4	Spatial mean
Year 1	Annual mean (μg/m³)	12.7				12.7
	% data completeness	80	0	0	0	
Year 2	Annual mean (μg/m³)	12.6	17.5	15.2		15.05
	% data completeness	90	63	38	0	
Year 3	Annual mean (μg/m³)	12.5	18.5	14.1	16.9	15.50
	% data completeness	90	80	85	50	
3-year mean						14.42

b. The data from these sites are averaged in the order described in section 2.1 of this appendix. Note that the annual mean from site #3 in year 2 and the annual mean from site #4 in year 3 do not meet the 75 percent data completeness criteria. Assuming the 38 percent data completeness represents a quarter with fewer than 11 samples, site #3 in year 2 does not meet the minimum data completeness requirement of 11 samples in each quarter. The site is therefore excluded from the calculation of the spatial mean for year 2. However, since the spatial mean for year 3 is above the level of the standard and the minimum data requirement of 11 samples in each quarter has been met, the annual mean from site #4 in year 3 is included in the calculation of the spatial mean for year 3 and in the calculation of the 3-year average. The 3-year average is rounded to 14.4 μg/m³, indicating that this area meets the annual $PM_{2.5}$ standard.

Example 2—Area With Two Monitors at the Same Location That Meets the Primary Annual $PM_{2.5}$ Standard.

a. In an area designated for spatial averaging, six designated monitors, with two monitors at the same location (#5 and #6), recorded data in a particular 3-year period. Using Equations 1 and 2, the annual means for $PM_{2.5}$ are calculated for each year. The following table can be created from the results.

Table 2.—Results From Equations 1 and 2

Annual mean (μg/m³)	Site #1	Site #2	Site #3	Site #4	Site #5	Site #6	Average of #5 and #6	Spatial mean
Year 1	12.9	9.9	12.6	11.1	14.5	14.6	14.55	12.21
Year 2	14.5	13.3	12.2	10.9	16.1	16.0	16.05	13.39
Year 3	14.4	12.4	11.5	9.7	12.3	12.1	12.20	12.04
3-Year mean								12.55

b. The annual means for sites #5 and #6 are averaged together using Equation 4 before the spatial average is calculated using Equation 3 since they are in the same location. The 3-year mean is rounded to 12.6 μg/m³, indicating that this area meets the annual $PM_{2.5}$ standard.

Example 3—Area With a Single Monitor That Meets the Primary Annual $PM_{2.5}$ Standard.

a. Given data from a single monitor in an area, the calculations are as follows. Using Equations 1 and 2, the annual means for $PM_{2.5}$ are calculated for each year. If the annual means are 10.28, 17.38, and 12.25 μg/m³, then the 3-year mean is:

$$\bar{x} = (1/3) \times (10.28 + 17.38 + 12.25) = 13.303\ \mu g/m^3.$$

b. This value is rounded to 13.3, indicating that this area meets the annual $PM_{2.5}$ standard.

2.6 *Equations for the 24-Hour $PM_{2.5}$ Standard.*

(a) When the data for a particular site and year meet the data completeness requirements in section 2.2 of this appendix, calculation of the 98th percentile is accomplished by the following steps. All the daily values from a particular site and year comprise a series of values (x_1, x_2, x_3, ..., x_n), that can be sorted into a series where each number is equal to or larger than the preceding number ($x_{[1]}$, $x_{[2]}$, $x_{[3]}$, ..., $x_{[n]}$). In this case, $x_{[1]}$ is the smallest number and $x_{[n]}$ is the largest value. The 98th percentile is found from the sorted series of daily values which is ordered from the lowest to the highest number. Compute $(0.98) \times (n)$ as the number ''i.d'', where ''i'' is the integer part of the result and ''d'' is the decimal part of the result. The 98th percentile value for year y, $P_{0.98,\,y}$, is given by Equation 6:

Equation 6

$$P_{0.98,y} = X_{[i+1]}$$

where:

$P_{0.98,y}$ = 98th percentile for year y;

$x_{[i+1]}$ = the $(i+1)^{th}$ number in the ordered series of numbers; and

i = the integer part of the product of 0.98 and n.

(b) The 3-year average 98th percentile is then calculated by averaging the annual 98th percentiles:

Equation 7

$$P_{0.98} = \frac{\sum_{y=1}^{3} P_{0.98,y}}{3}$$

(c) The 3-year average 98th percentile is rounded according to the conventions in section 2.3 of this appendix before a comparison with the standard is made.

Example 4—Ambient Monitoring Site With Every-Day Sampling That Meets the Primary 24-Hour $PM_{2.5}$ Standard.

a. In each year of a particular 3 year period, varying numbers of daily $PM_{2.5}$ values (e.g., 281, 304, and 296) out of a possible 365 values were recorded at a particular site with the following ranked values (in $\mu g/m^3$):

Table 3.—Ordered Monitoring Data For 3 Years

Year 1		Year 2		Year 3	
j rank	X_j value	j rank	X_j value	j rank	X_j value
275	57.9	296	54.3	290	66.0
276	59.0	297	57.1	291	68.4
277	62.2	298	63.0	292	69.8

b. Using Equation 6, the 98th percentile values for each year are calculated as follows:

$$0.98 \times 281 = 275.38 \Rightarrow i+1 = 276 \Rightarrow P_{0.98,1} = X_{[276]} = 59.0 \mu g / m^3$$

$$0.98 \times 304 = 297.92 \Rightarrow i+1 = 298 \Rightarrow P_{0.98,2} = X_{[298]} = 63.0 \mu g / m^3$$

$$0.98 \times 296 = 290.07 \Rightarrow i+1 = 291 \Rightarrow P_{0.98,3} = X_{[291]} = 68.4 \mu g / m^3$$

c. 1. Using Equation 7, the 3-year average 98th percentile is calculated as follows:

$$P_{0.98} = \frac{59.0 + 63.0 + 68.4}{3} = 63.46 \mu g / m^3, \text{ which rounds to } 63 \mu g / m^3.$$

2. Therefore, this site meets the 24-hour $PM_{2.5}$ standard.

3.0 *Comparisons with the PM_{10} Standards.*

3.1 *Annual PM_{10} Standard.*

(a) The annual PM_{10} standard is met when the 3-year average of the annual mean PM_{10} concentrations at each monitoring site is less than or equal to 50 $\mu g/m^3$. The 3-year average of the annual means is determined by averaging quarterly means to obtain annual mean PM_{10} concentrations for 3 consecutive, complete years at each monitoring site. The steps can be summarized as follows:

(1) Average 24-hour measurements to obtain a quarterly mean.

(2) Average quarterly means to obtain an annual mean.

(3) Average annual means to obtain a 3-year mean.

(b) For the annual PM_{10} standard, a year meets data completeness requirements when at least 75 percent of the scheduled sampling days for each quarter have valid data. However, years with high concentrations and more than a minimal amount of data (at least 11 samples in each quarter) shall not be ignored just because they are comprised of quarters with less than complete data. Thus, in computing the 3-year average annual mean concentration, years containing quarters with at least 11 samples but less than 75 percent data completeness shall be included in the computation if the annual mean concentration (rounded according to the conventions of section 2.3 of this appendix) is greater than the level of the standard.

(c) Situations may arise in which there are compelling reasons to retain years containing quarters which do not meet the data completeness requirement of 75 percent or the minimum number of 11 samples. The use of less than complete data is subject to the approval of the appropriate Regional Administrator.

(d) The equations for calculating the 3-year average annual mean of the PM_{10} standard are given in section 3.5 of this appendix.

3.2 *24-Hour PM_{10} Standard.*

(a) The 24-hour PM_{10} standard is met when the 3-year average of the annual 99th percentile values at each monitoring site is less than or equal to 150 $\mu g/m^3$. This comparison shall be based on 3 consecutive, complete years of air quality data. A year meets data completeness requirements when at least 75 percent of the scheduled sampling days for each quarter have valid data. However, years with high concentrations shall not be ignored just because they are comprised of quarters with less than complete data. Thus, in computing the 3-year average of the annual 99th percentile values, years containing quarters with less than 75 percent data completeness shall be included in the computation if the annual 99th percentile value (rounded according to the conventions of section 2.3 of this appendix) is greater than the level of the standard.

(b) Situations may arise in which there are compelling reasons to retain years containing quarters which do not meet the data completeness requirement. The use of less than complete data is subject to the approval of the appropriate Regional Administrator.

(c) The equation for calculating the 3-year average of the annual 99th percentile values is given in section 2.6 of this appendix.

3.3 *Rounding Conventions.* For the annual PM_{10} standard, the 3-year average of the annual PM_{10} means shall be rounded to the nearest 1 $\mu g/m^3$ (decimals 0.5 and greater are

rounded up to the next whole number, and any decimal less than 0.5 is rounded down to the nearest whole number). For the 24-hour PM_{10} standard, the 3-year average of the annual 99th percentile values of PM_{10} shall be rounded to the nearest 10 μg/m³ (155 μg/m³ and greater would be rounded to 160 μg/m³ and 154 μg/m³ and less would be rounded to 150 μg/m³).

3.4 *Monitoring Considerations.* Section 58.13 of this chapter specifies the required minimum frequency of sampling for PM_{10}. Exceptions to the specified sampling frequencies, such as a reduced frequency during a season of expected low concentrations, are subject to the approval of the appropriate Regional Administrator. For making comparisons with the PM_{10} NAAQS, all sites meeting applicable requirements in part 58 of this chapter would be used.

3.5 *Equations for the Annual PM_{10} Standard.*

(a) An annual arithmetic mean value for PM_{10} is determined by first averaging the 24-hour values of a calendar quarter using the following equation:

Equation 8

$$\bar{x}_{q,y} = \frac{1}{n_q}\sum_{i=1}^{n_q} x_{i,q,y}$$

where:

$\bar{x}_{q,y}$ = the mean for quarter q of year y;

n_q = the number of monitored values in the quarter; and

$x_{i,q,y}$ = the i^{th} value in quarter q for year y.

(b) The following equation is then to be used for calculation of the annual mean:

Equation 9

$$\bar{x}_y = \frac{1}{4}\sum_{q=1}^{4} \bar{x}_{q,y}$$

where:

$\bar{x}_y$ = the annual mean concentration for year y, (y=1, 2, or 3); and

$x_{q,y}$ = the mean for a quarter q of year y.

(c) The 3-year average of the annual means is calculated by using the following equation:

Equation 10

$$\bar{x} = \frac{1}{3}\sum_{y=1}^{3} \bar{x}_y$$

where:

$\bar{x}$ = the 3-year average of the annual means; and

$\bar{x}_y$ = the annual mean for calendar year y.

Example 5—Ambient Monitoring Site That Does Not Meet the Annual PM_{10} Standard.

a. Given data from a PM_{10} monitor and using Equations 8 and 9, the annual means for PM_{10} are calculated for each year. If the annual means are 52.42, 82.17, and 63.23 μg/m³, then the 3-year average annual mean is:

$$\bar{x} = (1/3) \times (52.42 + 82.17 + 63.23) = 65.94, \text{ which is rounded to } 66\ \mu g/m^3.$$

b. Therefore, this site does not meet the annual PM_{10} standard.

3.6 *Equation for the 24-Hour PM_{10} Standard.*

(a) When the data for a particular site and year meet the data completeness requirements in section 3.2 of this appendix, calculation of the 99th percentile is accomplished by the following steps. All the daily values from a particular site and year comprise a series of values (x_1, x_2, x_3, ..., x_n) that can be sorted into a series where each number is equal to or larger than the preceding number ($x_{[1]}$, $x_{[2]}$, $x_{[3]}$, ..., $x_{[n]}$). In this case, $x_{[1]}$ is the smallest number and x[n] is the largest value. The 99th percentile is found from the sorted series of daily values which is ordered from the lowest to the highest number. Compute (0.99) × (n) as the number ''i.d'', where ''i'' is the integer part of the result and ''d'' is the decimal part of the result. The 99th percentile value for year y, $P_{0.99,y}$, is given by Equation 11:

Equation 11

$$P_{0.99,y} = X_{[i+1]}$$

where:

$P_{0.99,y}$ = the 99th percentile for year y;

$x_{[i+1]}$ = the (i+1)th number in the ordered series of numbers; and

i = the integer part of the product of 0.99 and n.

(b) The 3-year average 99th percentile value is then calculated by averaging the annual 99th percentiles:

Equation 12

$$P_{0.99} = \frac{\sum_{y=1}^{3} P_{0.99,y}}{3}$$

(c) The 3-year average 99th percentile is rounded according to the conventions in section 3.3 of this appendix before a comparison with the standard is made.

Example 6—Ambient Monitoring Site With Sampling Every Sixth Day That Meets the Primary 24-Hour PM_{10} Standard.

a. In each year of a particular 3 year period, varying numbers of PM_{10} daily values (e.g., 110, 98, and 100) out of a possible 121 daily values were recorded at a particular site with the following ranked values (in μg/m³):

Table 4.—Ordered Monitoring Data For 3 Years

Year 1		Year 2		Year 3	
j rank	X_j value	j rank	X_j value	j rank	X_j value
108	120	96	143	98	140
109	128	97	148	99	144
110	130	98	150	100	147

b. Using Equation 11, the 99th percentile values for each year are calculated as follows:

$$0.99 \times 110 = 108.9 \Rightarrow i+1 = 109 \Rightarrow P_{0.99,1} = X_{[109]} = 128 \mu g/m^3$$

$$0.99 \times 98 = 97.02 \Rightarrow i+1 = 98 \Rightarrow P_{0.99,2} = X_{[98]} = 150 \mu g/m^3$$

$$0.99 \times 100 = 99 \Rightarrow i + 1 = 100 \Rightarrow P_{0.99,3} = X_{[100]} = 147 \mu g / m^3$$

c. 1. Using Equation 12, the 3-year average 99th percentile is calculated as follows:

$$\frac{128 + 50 + 147}{3} = 141.7 \ \mu g / m^3 \text{ rounds to } 140 \mu g / m^3.$$

2. Therefore, this site meets the 24-hour PM_{10} standard.

Air Quality Designations and Classifications for the Fine Particles (PM2.5) National Ambient Air Quality Standards; Final Rule

ENVIRONMENTAL PROTECTION AGENCY

40 CFR Part 81

[OAR–2003–0061; FRL–7856–1]

RIN–2060–AM04

Air Quality Designations and Classifications for the Fine Particles (PM2.5) National Ambient Air Quality Standards

AGENCY: Environmental Protection Agency (EPA).

ACTION: Final rule.

SUMMARY: This rule sets forth the initial air quality designations and classifications for all areas in the United States, including Indian country, for the fine particles (PM2.5) National Ambient Air Quality Standards (NAAQS). The EPA is issuing this rule so that citizens will know whether the air quality where they live and work is healthful or unhealthful. Health studies have shown significant associations between exposure to PM2.5 and premature death from heart or lung disease. Fine particles can also aggravate heart and lung diseases and have been linked to effects such as cardiovascular symptoms, cardiac arrhythmias, heart attacks, respiratory symptoms, asthma attacks, and bronchitis. These effects can result in increased hospital emissions, emergency room visits, absences from school or work, and restricted activity days.

Individuals that may be particularly sensitive to PM2.5 exposure include people with heart or lung disease, older adults, and children. This rule establishes the boundaries for areas designated as nonattainment, unclassifiable, or attainment/unclassifiable. This rule does not establish or address State and Tribal obligations for planning and control requirements that apply to nonattainment areas for the PM2.5 standards. The EPA will publish a separate rule which will set forth the planning and control requirements that apply to nonattainment areas for the PM2.5 standards.

DATES: The effective date of this rule is April 5, 2005.

ADDRESSES: The EPA has established a docket for this action under Docket ID NO. OAR–2003–0061. All documents in the docket are listed in the EDOCKET index at *http://www.epa.gov/edocket*. Although listed in the index, some information is not publicly available *i.e.*, Confidential Business Information (CBI) or other information whose disclosure is restricted by statute. Certain other material, such as copyrighted material, is not placed on the Internet and will be publicly available only in hard copy form. Publicly available docket materials are available either electronically in the EDOCKET or in hard copy at the Docket, EPA/DC, EPA West, Room B102, 1301 Constitution Ave., NW., Washington, DC. The Public Reading Room is open from 8:30 a.m. to 4:30 p.m. Monday through Friday, excluding legal holidays. The telephone number for the Public Reading Room is (202) 566–1744, and the telephone number for the Office of Air and Radiation Docket and Information Center is (202) 566–1742. In addition, we have placed a copy of the rule and a variety of materials regarding designations on EPA's designation Web site at: *http://www.epa.gov/oar/oaqps/particles/designations/index.htm* and on the Tribal Web site at: *http://www/epa.gov/air/tribal*.

FOR FURTHER INFORMATION CONTACT: Designations: Mr. Rich Damberg, Office of Air Quality Planning and Standards, U.S. Environmental Protection Agency, Mail Code C504–02, Research Triangle Park, NC 27711, phone number (919) 541–5592 or by e-mail at: *damberg.rich@epa.gov*.

Designations and Part 81 Code of Federal Regulations: Dr. Larry D. Wallace, Office of Air Quality Planning and Standards, U.S. Environmental Protection Agency, Mail Code C504–02, Research Triangle Park, NC 27711, phone number (919) 541–0906 or by e-mail at: *wallace.larry@epa.gov*.

Technical Issues Related to Designations: Mr. Thomas Rosendahl, Office of Air Quality Planning and Standards, U.S. Environmental Protection Agency, Mail Code C504–02, Research Triangle Park, NC 27711, phone number (919) 541–5314 or by e-mail at: *rosendahl.tom@epa.gov*.

PM2.5 Air Quality Data Issues: Mr. Mark Schmidt, Office of Air Quality Planning and Standards, U.S. Environmental Protection Agency, Mail Code C304–01, Research Triangle Park, NC 27711, phone number (919) 541–5314 or by e-mail at: *schmidt.mark@epa.gov*.

TSD Technical Support Document
U.S. United States
VOC Volatile Organic Compounds

II. What Is the Purpose of This Document?

The purpose of this document is to announce and promulgate designations and boundaries for areas of the country with respect to the PM2.5 NAAQS in accordance with the requirements of the CAA. The list of areas in each State, the boundaries of each area, and the designation of each area, appear in the table at the end of this final rule. This rule was signed by the EPA Administrator, Mike Leavitt, on December 17, 2004. Several steps were taken to announce that this rule is available. We posted the notice on several EPA Web sites and provided a copy of the rule to States and Tribes.

III. What Are Fine Particles?

Fine particles in the atmosphere are made up of a complex mixture of components. Common constituents include: sulfate (SO_4); nitrate (NO_3); ammonium (NH4); elemental carbon; a great variety of organic compounds; water; and inorganic material (including metals, dust, sea salt, and other trace elements), which often is categorized as ''crustal'' material. Airborne particles with a nominal aerodynamic diameter of 2.5 micrometers or less (a micrometer is one-millionth of a meter; 2.5 micrometers is less than about one-thirtieth the thickness of a human hair) are considered to be ''fine particles,'' and are also known as PM2.5. ''Primary'' particles are emitted directly into the air as a solid or liquid particle (*e.g.*, elemental carbon and organic particles from diesel engines or burning activities). ''Secondary'' particles (*e.g.*, sulfate and nitrate) form in the atmosphere as a result of various chemical transformations of gaseous precursors such as sulfur dioxide (SO_2) and oxides of nitrogen (NO_X).

IV. What Are the Health Concerns Addressed by the PM2.5 Standard?

Epidemiological studies have shown a significant association between elevated PM2.5 levels and a number of serious health effects, including premature mortality, aggravation of respiratory and cardiovascular disease (as indicated by increased hospital admissions, emergency room visits, absences from school or work, and restricted activity days), lung disease, decreased lung function, asthma attacks, and certain cardiovascular problems such as heart attacks and cardiac arrhythmia. Individuals particularly sensitive to PM2.5 exposure include older adults, people with heart and lung disease, and children.

More information on the health effects of PM2.5 can be found at the following Web site: *http://www.epa.gov/ttn/naaqs/pm/pm25_index.html*.

V. What Is the Chronology of Events Leading Up to This Rule?

This section summarizes the relevant activities leading up to today's action, including promulgation of the PM2.5 NAAQS and litigation challenging that standard. The CAA establishes a process for air quality management through the establishment and implementation of the NAAQS. After the promulgation of a new or revised NAAQS, EPA is required to designate areas, pursuant to section 107(d)(1) of the CAA, as attainment, nonattainment, or unclassifiable.

On July 18, 1997, EPA revised the NAAQS for particulate matter to add new standards for PM2.5, using PM2.5 as the indicator for the pollutant. The EPA established health-based (primary) annual and 24-hour standards for PM2.5 (62 FR 38652). The annual standard is a level of 15 micrograms per cubic meter, based on a 3-year average of annual mean PM2.5 concentrations. The

24-hour standard is a level 65 micrograms per cubic meter, based on a 3-year average of the 98th percentile of 24-hour concentrations. The EPA established the standards based on significant evidence and numerous health studies demonstrating that serious health effects are associated with exposures to particulate matter.

The PM2.5 NAAQS were challenged by numerous litigants and in May 1999, the U.S. Court of Appeals for the D.C. Circuit issued a decision remanding, but not vacating, the standards. *American Trucking Assoc.* v. *EPA*, 175 F.3d 1027, 1047–48, *on rehearing* 195 F.3d 4 (D.C. Cir., 1999). The EPA sought review of two aspects of that decision in the U.S. Supreme Court. The Supreme Court upheld the PM2.5 standards. *EPA* v. *American Trucking Assoc.*, 531 U.S. 457 (2001). In March 2002, the D.C. Circuit rejected all remaining challenges to the PM2.5 standards, *American Trucking Assoc.* v. *EPA*, 283 F.3d 355 (D.C. Cir., 2002). Since final resolution of the litigation over the PM2.5 NAAQS, EPA has been acting to implement the standards.

The process for designating areas following promulgation of a new or revised NAAQS is contained in section 107(d)(1) of the CAA. In June 1998, Congress adopted the Transportation Equity Act for the 21st Century (TEA–21). Section 6102(c)(1)(d) of TEA–21 amended section 107 of the CAA by extending the time period for EPA to initiate the designations process for the PM2.5 NAAQS until 3 calendar years of air quality data, measured at Federal Reference Method monitors, were gathered. The EPA and State air quality agencies initiated the monitoring process for the PM2.5 NAAQS in 1999, and deployed all air quality monitors by January 2001. The EPA is designating areas across the country for the PM2.5 NAAQS based upon air quality monitoring data from these monitors for calendar years 2001–2003.

VI. What Are the Clean Air Act (CAA) Requirements for Air Quality Designations and What Action has EPA Taken to Meet These Requirements?

This section summarizes the provisions of section 107(d)(1) of the CAA which governs the process that States and EPA must follow in order to recommend and promulgate designations. Following the promulgation of a new or revised standard, each State Governor or Tribal leader has an opportunity to recommend air quality designations, including the appropriate boundaries for areas, to EPA. By no later than 120 days prior to promulgating designations, EPA is required to notify States or Tribes of any intended modifications to their boundaries that EPA deems necessary. States and Tribes then have an opportunity to provide a demonstration as to why the proposed modification indicated by EPA is inappropriate. Whether or not a State or Tribe provides a recommendation, EPA must promulgate the designation that it deems appropriate.

In April 2003, EPA requested that States and Tribes submit their designation recommendations and supporting documentation to EPA by February 15, 2004. After receiving recommendations from the States and Tribes and carefully reviewing and evaluating each recommendation, EPA on June 28 and 29, 2004, provided a response to each State and Tribe indicating whether or not EPA intended to make modifications to the initial recommendations, and explaining EPA's reasons for making any such modifications. The EPA provided an opportunity for States and Tribes to respond to any proposed modifications to their initial boundary recommendations until September 1, 2004. In response to our June 28 and 29, 2004 letters, EPA received letters from many States and Tribes suggesting changes to EPA's modifications and providing additional information. The EPA evaluated each supplemental letter, and all of the timely technical support information provided, before arriving at the final designation decisions reflected in today's action. Some of the designations reflect our modifications to the State and Tribal recommendations. We have placed these State and Tribal letters, and our responses to the issues contained in them, in the EPA docket for this action.

Tribal designation activities are covered under the authority of section 301(d) of the CAA. This provision of the CAA authorizes EPA to treat eligible Indian Tribes in the same manner as States. Pursuant to section 301(d)(2), we promulgated regulations, known as the Tribal Authority Rule (TAR), on February 12, 1999. 63 FR 7254, codified at 40 CFR 49 (1999). This rule specifies those provisions of the CAA for which it is appropriate to treat Tribes as States. Under the TAR, Tribes may choose to develop and implement their own CAA programs, but are not required to do so. The TAR also establishes procedures and criteria by which Tribes may request from EPA a determination of eligibility for such treatment. The designations process contained in section 107(d) of the CAA is included among those provisions determined to be appropriate by EPA for treatment of Tribes in the same manner as States. As authorized by the TAR, Tribes may request an opportunity to submit designation recommendations to us. In cases where Tribes do not make their own recommendations, EPA, in consultation with the Tribes, will promulgate the designation that EPA deems appropriate on their behalf. All Tribes were invited to submit recommendations concerning designations for PM2.5.

The EPA worked with the Tribes that requested an opportunity to submit designation recommendations. Eligible Tribes were provided an opportunity to submit their own recommendations and supporting documentation. The EPA reviewed the recommendations made by Tribes and, in consultation with the Tribes, made modifications as deemed necessary and appropriate. Under the TAR, Tribes generally are not subject to the same submission schedules imposed by the CAA on States.

VII. What Guidance Did EPA Issue and How Did EPA Apply the Statutory Requirements and Applicable Guidance To Determine Boundaries for the PM2.5 NAAQS?

Section 107(d)(1)(A)(I) of the CAA defines a nonattainment area as an area that is violating an ambient standard or is contributing to air quality in a nearby area that is violating the standard. If an area meets either prong of this definition, then EPA is obligated to designate the area as nonattainment. Section 107(d)(1)(A)(iii) provides that any area which EPA cannot designate on the basis of available information as meeting or not meeting the standards should be designated unclassifiable.

In April 2003, EPA issued designation guidance concerning how to determine the boundaries for PM2.5 nonattainment areas.[1] The guidance provided that EPA would use the 3 most recent calendar years of monitoring data for PM2.5 to determine each county's designation. For today's PM2.5 designations, we are basing our decision on air quality monitoring data from calendar years 2001–2003. When evaluating individual areas, we started with the premise that data recorded by a PM2.5 monitor in most cases represents air quality throughout the area in which it is located. In addition, we considered the county boundary as the basic jurisdictional boundary for determining the extent of the area reflected by the PM2.5 monitor. As a result, if a PM2.5

[1] *See* ''Designations for the Fine Particle National Ambient Air Quality Standards.'' memorandum to Regional Administrators, Regions I–X, from Jeffrey R. Holmstead, Assistant Administrator, OAR, dated April 1, 2003.

monitor was violating the standard based on the 2001–2003 data, at a minimum we designated the entire county where that monitor is located as nonattainment. We made exceptions to this approach in a few very large western counties where a significant geographic feature such as a mountain range divided a county, resulting in different air quality in different parts of the county. In such cases, we considered designations of partial counties to be appropriate. After identifying the counties with violating monitors, we then proceeded to identify nearby counties that were potentially contributing to the violation(s) at the monitors.

In assessing whether nearby areas contributed to a violation, EPA started with the Consolidated Metropolitan Statistical Area (CMSA) and the Metropolitan Statistical Area (MSA) as the presumptive boundaries for PM2.5 nonattainment areas. A metropolitan area, as defined by the Office of Management and Budget (OMB) in 1999, consisted of a single MSA in some cases, or a CMSA in other cases. These metropolitan areas provide boundaries for the geographic extent of urban areas. We suggested the use of metropolitan area boundaries as the presumptive boundaries for urban nonattainment areas for air quality purposes, based upon evidence that violations of the PM2.5 air quality standards generally include a significant urban-scale contribution as well as a regional contribution. The actual size of each nonattainment area may be larger or smaller than the presumptive boundaries, depending upon the application of the nine factors contained in the April 2003 designations guidance for PM2.5.

In June 2003, OMB released a new list of metropolitan area descriptions. Because we had already issued the April 2003 designations guidance which recommended use of the 1999 OMB metropolitan definitions as a starting point, and because States and Tribes were already actively using this guidance in their planning efforts, we decided that it would be disruptive to recommend the use of the 2003 OMB definitions as the presumptive boundaries. Instead, we issued a second guidance memorandum in February 2004, which indicated that we would continue to consider the 1999 MSA boundaries as the presumptive boundaries, but that States should nevertheless take into consideration the 2003 OMB revised MSA boundaries. We particularly urged consideration of the 2003 MSA boundaries for those counties that OMB added to an existing metropolitan area due to growth, or because of a high degree of social and economic integration with the primary urban area.[2]

The April 2003 guidance memorandum described nine factors that EPA would take into consideration in determining appropriate nonattainment area boundaries, whether larger or smaller than the presumptive boundaries: (1) Emissions and air quality in adjacent areas (including adjacent CMSAs and MSAs), (2) air quality in potentially included versus excluded areas, (3) population density and degree of urbanization including commercial development in included versus excluded areas, (4) traffic and commuting patterns, (5) expected growth (including extent, pattern and rate of growth), (6) meteorology (weather/transport patterns), (7) geography/topography (*e.g.*, mountain ranges or other air basin boundaries), (8) jurisdictional boundaries (*e.g.*, counties, air districts, Reservations, etc.), and (9) level of existing controls on emission sources.

In assessing emissions under the first factor, we developed a ''weighted emissions score'' that valued the effect of direct emissions of PM2.5 and its precursors that contribute to ''urban excess'' PM2.5 concentrations at monitor sites. The ''urban excess'' concentrations for each PM2.5 component (direct or precursor emissions) are calculated from two PM2.5 speciation monitors by subtracting the regional concentration from the urban concentration for each component. The methodology we used to calculate urban excess concentration and the weighted emission score is explained in more detail in the technical support document (TSD).

We used this metric to compare the relative emissions contribution of different counties in and around each metropolitan area. Using this approach, we were able to take into consideration, in a single metric, the county-level emissions of carbonaceous particles, inorganic particles, SO_2, and NO_X (all of which contribute to PM2.5 formation) in the vicinity of each violating monitor. By comparing weighted emissions scores across counties in a metropolitan area, EPA was able to identify those counties having the highest estimated emissions contribution to the local nonattainment problem. In addition, by examining the data from the urban speciation monitors, we could draw some conclusions concerning the likely sources of emissions contributing to the violation. Knowing the likely sources of the emissions, we could better evaluate which of the nearby counties had emissions likely to be contributing to the ambient concentrations at the violating monitor.

Evaluation of the weighted emissions score and speciation data was an important element in our nine factor analysis, and we believe that it provided a reasonable tool for evaluating the relative contribution of nearby areas to violations at a monitor, given the variety of precursors and sources that participate in the formation of PM2.5. Further discussion of the weighted emissions score, and area-specific explanations of its application, appear in the TSD.

In some cases, considering the factors and additional information provided by the State, we determined that only part of a nearby county (*e.g.*, the part of the county that contained the significant sources of contributing emissions) should be considered as contributing to the violation at the monitor, and therefore included only a portion of that adjacent county in the nonattainment area. In other cases, we determined that the emissions from an identifiable large power plant in a county were contributing to the violations in a nearby area. In these cases, we concluded that it was appropriate to designate only the portion of the county where the source is located, even if that portion is not contiguous with the remainder of the nonattainment area. We adopted this approach where we determined, following the nine factor analysis, that it would be inappropriate to include other portions of a county, merely because those portions lay between the large stationary source and the remainder of the designated nonattainment area. We selected the boundaries for these noncontiguous portions of nonattainment areas by relying on legally recognized governmental boundaries (*e.g.*, townships, tax districts, or census blocks) in which the source is located.

We believe that the individual facts and circumstances of each area must be considered in determining whether to include a county as contributing to a particular nonattainment problem. Thus, our guidance does not establish bright lines or cut-points for how a particular factor is applied. For example, the guidance does not identify a set amount of a pollutant, or a specific level of commuting between counties, that would automatically require a county to be included in a nonattainment area as a contributing

[2] See ''Additional Guidiance on Defining Area Boundaries for PM–2.5 Designations,'' memorandum to Air Division Directors. Regions I–X, from Lydia N. Wegman, Director, AQSSD, dated February 13, 2004.

county. We analyzed the information provided by each State or Tribe in its recommendation letter, subsequently submitted information, and any other pertinent information available to EPA, in order to determine whether a county should be designated nonattainment. We evaluated each State's or Tribe's designation recommendation in light of the nine factors, bringing to bear our best technical and policy judgement. If the result of the evaluation showed that a county, whether inside or outside of the CMSA or MSA contributes to the violation in a nearby area with a violating monitor, we designated the area as nonattainment.

In a small number of areas, EPA concluded that there was insufficient information to designate a given area as either nonattainment or attainment/unclassifiable. In these instances, we have designated the area as unclassifiable. In each instance, these areas had violating monitors for the years 2000–2002, but incomplete data or other data issues for the years 2001–2003. Further explanation of the unclassifiable designations may be found in the TSD for this action.

The EPA did not rely on planned or potential regional PM2.5 reduction strategies in making decisions regarding nonattainment designations, even if those strategies predict that an area may attain the standard in the future. We recognize that some areas with a violating monitor may be projected to come into attainment in the future without additional local emission controls because of State and/or national programs that will reduce transported emissions. However, the CAA requires EPA to make nonattainment designations based on current data. While we cannot consider projected future attainment in determining current designations, we intend to expedite the redesignation of areas to attainment once they monitor clean air quality. We also intend to apply our policy which streamlines the planning process for nonattainment areas that are meeting the NAAQS but are not yet redesignated to attainment.[3]

Today's designation action is a final rule which establishes designations for all areas of the country for the PM2.5 NAAQS. In this action, we have added regulatory text to provide for the amendment of 40 CFR part 81 to identify the designation of areas across the country for the PM2.5 standard.

VIII. Has EPA Used 2004 Air Quality Data?

The final PM2.5 designations announced in today's action are based upon air quality data for calendar years 2001 through 2003. Over the course of the designations process, a number of States have provided comments to EPA suggesting that the agency should delay designations in order to permit consideration of additional air quality data from 2004 as a part of the designation decision. As discussed above, EPA must by law make the designations by December 31, 2004. This statutory deadline and the practical difficulties of obtaining complete,[4] quality assured, certified data for calendar year 2004 by December 31, 2004, have precluded EPA from using 2004 data for today's action. Under normal circumstances, we would not expect such data to be available for some time following the end of the calendar year, and under the applicable regulations States would not be required to have submitted such data until April 1, 2005, and would not be required to have certified such data until July 1, 2005. However, because we are promulgating the designations so near the end of calendar year 2004, and because complete, quality assured, certified 2004 data may become available for some areas quickly, we are interested in providing a process by which we could utilize 2004 data where possible in the designation process.

We have provided that the final PM2.5 designations announced in today's action will be effective on the date 90 days following the date of publication. If any State submits complete, quality assured, certified 2004 data to EPA by February 22, 2005, that suggest that a change of designation status is appropriate for any area within that State, and we agree that a change of designation status is appropriate, then we will withdraw the designation announced in today's action for such area and issue another designation that reflects the inclusion of 2004 data. We emphasize that we will conduct this process only for those States that submit the necessary complete, quality assured, certified data by the deadline and in those instances where we can complete the analysis and effect the change of designation status before the original effective date established by today's final action.

If inclusion of 2004 data causes an area to change from nonattainment to attainment, EPA will change the designation if every county in the area is neither monitoring a violation of the standards nor contributing to a violation of the standards in another nearby area. If inclusion of 2004 data results in nonattainment in an area that was designated attainment, we will evaluate the reasons for the violation in the area and determine the appropriate course of action, which could include redesignation of the area to nonattainment. Also, EPA commits to evaluate 2004 data for unclassifiable areas when it receives complete, quality assured, certified data from the State, which is due no later than July 2005. At that time, EPA will determine whether a change of designation for an unclassifiable area is appropriate.

IX. How Do Designations Affect Indian Country?

All counties, partial counties or Air Quality Control Regions listed in the table at the end of this document are designated as indicated, and include Indian Country geographically located within such areas, except as otherwise indicated in the table.

As mentioned earlier in this document, EPA's guidance for determining nonattainment area boundaries presumes that the CMSA or MSA monitor forms the presumptive boundary of the nonattainment areas but that the size of the area can be larger or smaller depending on contribution to the violation from nearby areas and other air quality-related technical factors. In general, and consistent with relevant air quality information, EPA intends to include Indian country encompassed within the presumptive CMSA or MSA boundaries as within the boundaries of the area for designation purposes, in order to protect public health and welfare. The EPA anticipates that in most cases, relevant air quality information will indicate that areas of Indian country located within CMSAs or MSAs should have the same designation as the surrounding area. However, based on the nine factors outlined in our guidance, there may be instances where a different designation is appropriate.

A State recommendation for a designation of an area that surrounds Indian country does not indicate the designation for Indian country. However, the conditions that support a State's designation recommendation, such as air quality data at the location of the sources, may indicate the likelihood that similar conditions exists for the Indian country located in that

[3] *See* ''Clean Data Policy for the Fine Particle National Ambient Air Quality Standards'' memorandum to Air Division Directors, Regions I–X from Steve Page, Director, Office of Air Quality Planning and Standards, December 14, 2004.

[4] Fine particle monitoring data is to be determined as ''complete'' according to data handling regulations for the PM2.5 standards in 40 CFR Part 50, Appendix N (62 FR 138, July 18, 1997).

area. States generally have neither the responsibility nor the authority for planning and regulatory activities under the CAA in Indian country.

X. Where Can I Find Information Forming the Basis for This Rule and Exchanges Between EPA, States, and Tribes Related to This Rule?

Information providing the basis for today's action and related decisions are provided in the TSD. The TSD, applicable EPA guidance memoranda, copies of correspondence regarding this process between EPA and the States, Tribes, and other parties, and EPA's responses to comments, are available for review at the EPA Docket Center listed above in the addresses section of this document and on our designation Web site at *http://www.epa.gov/oar/oaqps/particles/designations/index.htm.* State specific information is available at the EPA Regional Offices.

XI. Statutory and Executive Order Reviews

Upon promulgation of a new or revised NAAQS, the CAA requires EPA to designate areas as attaining or not attaining the NAAQS. The CAA then specifies requirements for areas based on whether such areas are attaining or not attaining the NAAQS. In this final rule, EPA assigns designations to areas as required.

A. Executive Order 12866: Regulatory Planning and Review

Under Executive Order 12866 (58 FR 51735, October 4, 1993), EPA must determine whether the regulatory action is ''significant'' and, therefore, subject to OMB review and the requirements of the Executive Order. The order defines ''significant regulatory action'' as one that is likely to result in a rule that may: (1) Have an annual effect on the economy of $100 million or more or adversely affect in a material way the economy, a sector of the economy, productivity, competition, jobs, the environment, public health or safety, or State, local, or Tribal governments or communities; (2) create a serious inconsistency or otherwise interfere with an action taken or planned by another agency; (3) materially alter the budgetary impact of entitlements, grants, user fees, or loan programs or the rights and obligations of recipients thereof; or (4) raise novel legal or policy issues arising out of legal mandates, the President's priorities, or the principles set forth in the Executive Order.

Pursuant to the terms of Executive Order 12866, it has been determined that this rule is not a ''significant regulatory action'' because none of the above factors apply. As such, this final rule was not formally submitted to OMB for review.

B. Paperwork Reduction Act

This action does not impose an information collection burden under the provisions of the Paperwork Reduction Act, 44 U.S.C. 3501 *et seq.* This rule responds to the requirement to promulgate air quality designations after promulgation of a NAAQS. This requirement is prescribed in the CAA section 107 of title 1. The present final rule does not establish any new information collection apart from that required by law. Burden means that total time, effort, or financial resources expended by persons to generate, maintain, retain, or disclose or provide information to or for a Federal agency. This includes the time needed to review instructions; develop, acquire, install, and utilize technology and systems for the purposes of collecting, validating, and verifying information, processing and maintaining information, and disclosing and providing information; adjust the existing ways to comply with any previously applicable instructions and requirements; train personnel to be able to respond to a collection of information; search data sources; complete and review the collection of information; and transmit or otherwise disclose the information. An Agency may not conduct or sponsor, and a person is not required to respond to a collection of information unless it displays a currently valid OMB control number. The OMB control numbers for EPA's regulations in the CFR are listed in 40 CFR part 9.

C. Regulatory Flexibility Act

The Regulatory Flexibility Act (RFA) generally requires an agency to prepare a regulatory flexibility analysis of any rule subject to notice and comment rulemaking requirements under the Administrative Procedures Act or any other statute unless the agency certifies that the rule will not have a significant economic impact on a substantial number of small entities. Small entities include small businesses, small organizations, and small governmental jurisdictions.

For the purpose of assessing the impacts of today's final rule on small entities, small entity is defined as: (1) A small business that is a small industry entity as defined in the United States Small Business Administration (SBA) size standards (*See* 13 CFR part 121); (2) a small governmental jurisdiction that is a government of a city, county, town, school district or special district with a population of less than 50,000; and (3) a small organization that is any not-for-profit enterprise which is independently owned and operated and is not dominate in its field.

The rule designating nonattainment areas for the PM2.5 NAAQS is not subject to RFA because it was not subject to notice and comment rulemaking requirements. *See* CAA section 107(d)(2)(B).

After considering the economic impacts of today's final rule on small entities, I certify that this rule will not have a significant economic impact on a substantial number of small entities.

D. Unfunded Mandates Reform Act

Title II of the Unfunded Mandates Reform Act of 1995 (UMRA), Public Law 104–4, establishes requirements for Federal Agencies to assess the effects of their regulatory actions on State, local and Tribal governments and the private sector. Under section 202 of the UMRA, EPA generally must prepare a written statement, including a cost-benefit analysis, for proposed and final rules with ''Federal mandate'' that may result in expenditures to State, local, and Tribal governments, in the aggregate, or to the private sector, of $100 million or more in any 1 year. Before promulgating an EPA rule for which a written statement is needed, section 205 of the UMRA generally requires EPA to identify and consider a reasonable number of regulatory alternatives and adopt the least costly, most cost-effective or least burdensome alternative that achieves the objectives of the rule. The provisions of section 205 do not apply when they are inconsistent with applicable law. Moreover, section 205 allows EPA to adopt an alternative other than the least costly, most cost-effective or least burdensome alternative if the Administrator publishes with the final rule an explanation of why that alternative was not adopted. Before EPA establishes any regulatory requirements that may significantly or uniquely affect small governments, including Tribal governments, it must have developed under section 203 of the UMRA a small government agency plan. The plan must provide for notifying potentially affected small governments to have meaningful and timely input in the development of EPA regulatory proposals with significant Federal intergovernmental mandates, and informing, educating, and advising small government on compliance with regulatory requirements.

Today's final action does not include a Federal mandate within the meaning of UMRA that may result in expenditures of $100 million or more in any 1 year by either State, local, or

Tribal governments in the aggregate or to the private sector, and therefore, is not subject to the requirements of sections 202 and 205 of the UMRA. It does not create any additional requirements beyond those of the PM2.5 NAAQS (62 FR 38652; July 18, 1997), therefore, no UMRA analysis is needed. This rule establishes the application of the PM2.5 standard and the designation for each area of the country for the PM2.5 NAAQS. The CAA requires States to develop plans, including control measures, based on their designations and classifications.

One mandate that may apply as a consequence of this action to all designated nonattainment areas is the requirement under CAA section 176(c) and associated regulations to demonstrate conformity of Federal actions to State Implementation Plans (SIPs). These rules apply to Federal agencies and Metropolitan Planning Organizations (MPOs) making conformity determinations. The EPA concludes that such conformity determinations will not cost $100 million or more in the aggregate.

The EPA believes that any new controls imposed as a result of this action will not cost in the aggregate $100 million or more annually. Thus, this Federal action will not impose mandates that will require expenditures of $100 million or more in the aggregate in any 1 year.

Nonetheless, EPA carried out consultation with government entities affected by this rule, including States, Tribal governments, and local air pollution control agencies.

E. Executive Order 13132: Federalism

Executive Order 13132, entitled ''Federalism'' (64 FR 43255, August 10, 1999), requires EPA to develop an accountable process to ensure ''meaningful and timely input by State and local officials in the development of regulatory policies that have federalism implications.'' ''Policies that have federalism implications'' is defined in the Executive Order to include regulations that have ''substantial direct effects on the States, or the relationship between the national government and the States, or on the distribution of power and responsibilities among the various levels of government.''

This final rule does not have federalism implications. It will not have substantial direct effects on the States, on the relationship between the national government and the States, or on the distribution of power and responsibilities among the various levels of government, as specified in Executive Order 13132. The CAA establishes the scheme whereby States take the lead in developing plans to meet the NAAQS. This rule will not modify the relationship of the States and EPA for purposes of developing programs to implement the NAAQS. Thus, Executive Order 13132 does not apply to this rule.

F. Executive Order 13175: Consultation and Coordination With Indian Tribal Governments

Executive Order 13175, entitled ''Consultation and Coordination with Indian Tribal Governments'' (65 FR 67249, November 9, 2000), requires EPA to develop an accountable process to ensure ''meaningful and timely input by Tribal officials in the development of regulatory policies that have Tribal implications.'' This final rule does not have ''Tribal implications'' as specified in Executive Order 13175. This rule concerns the designation and classification of areas as attainment and nonattainment for the PM2.5 air quality standard. The CAA provides for States to develop plans to regulate emissions of air pollutants within their jurisdictions. The TAR provides Tribes the opportunity to develop and implement CAA programs such as programs to attain and maintain the PM2.5 NAAQS, but it leaves to the discretion of the Tribe the decision of whether to develop these programs and which programs, or appropriate elements of a program, the Tribe will adopt.

This final rule does not have Tribal implications as defined by Executive Order 13175. It does not have a substantial direct effect on one or more Indian Tribes, since no Tribe has implemented a CAA program to attain the PM2.5 NAAQS at this time. Furthermore, this rule does not affect the relationship or distribution of power and responsibilities between the Federal government and Indian Tribes. The CAA and the TAR establish the relationship of the Federal government and Tribes in developing plans to attain the NAAQS, and this rule does nothing to modify that relationship. Because this rule does not have Tribal implications, Executive Order 13175 does not apply.

Although Executive Order 13175 does not apply to this rule, EPA did outreach to Tribal leaders and environmental staff regarding the designations process. The EPA supports a national ''Tribal Designations and Implementation Work Group'' which provides an open forum for all Tribes to voice concerns to EPA about the designations and implementation process for the NAAQS, including the PM2.5 NAAQS. These discussions informed EPA about key Tribal concerns regarding designations as the rule was under development and gave Tribes the opportunity to express concerns about designations to EPA. Furthermore, EPA sent individualized letters to all federally recognized Tribes about EPA's intention to designate areas for the PM2.5 standard and gave Tribal leaders the opportunity for consultation.

G. Executive Order 13045: Protection of Children From Environmental Health and Safety Risks

Executive Order 13045: ''Protection of Children From Environmental Health and Safety Risks'' (62 FR 19885, April 23, 1997) applies to any rule that (1) is determined to be ''economically significant'' as defined under Executive Order 12866, and (2) concerns an environmental health and safety risk that EPA has reason to believe may have a disproportionate effect on children. If the regulatory action meets both criteria, EPA must evaluate the environmental health or safety effects of the planned rule on children, and explain why the planned regulation is preferable to other potentially effective and reasonably feasible alternatives considered by the EPA.

The final rule is not subject to Executive Order 13045 because it is not economically significant as defined in Executive Order 12866, and because EPA does not have reason to believe that the environmental health risks or safety risks addressed by this rule present a disproportionate risk or safety risk to children. Nonetheless, we have evaluated the environmental health or safety effects of the PM2.5 NAAQS on children. The results of this risk assessment are contained in the NAAQS for PM2.5, Final Rule (July 18, 1997, 62 FR 38652).

H. Executive Order 13211: Actions That Significantly Affect Energy Supply, Distribution, or Use

This rule is not subject to Executive Order 13211, ''Actions That Significantly Affect Energy Supply, Distribution, or Use,'' (66 FR 28355, May 22, 2001) because it is not a significant regulatory action under Executive Order 12866.

Information on the methodology and data regarding the assessment of potential energy impacts is found in Chapter 6 of U.S. EPA 2002, Cost, Emission Reduction, Energy, and the Implementation Framework for the PM2.5 NAAQS, prepared by the Innovative Strategies and Economics Group, Office of Air Quality Planning and Standards, Research Triangle Park, NC, April 24, 2003.

I. National Technology Transfer Advancement Act (NTTAA)

Section 12(d) of the NTTAA of 1995, Public Law No. 104–113, section 12(d) (15 U.S.C. 272 note) directs EPA to use voluntary consensus standards (VCS) in its regulatory activities unless to do so would be inconsistent with applicable law or otherwise impracticable. Voluntary consensus standards are technical standards (*e.g.*, materials specifications, test methods, sampling procedures, and business practices) that are developed or adopted by VCS bodies. The NTTAA directs EPA to provide Congress, through OMB, explanations when the Agency decides not to use available and applicable VCS.

This action does not involve technical standards. Therefore, EPA did not consider the use of any VCS.

J. Congressional Review Act

The Congressional Review Act, 5 U.S.C. 801 *et seq.*, as added by the Small Business Regulatory Enforcement Fairness Act of 1996, generally provides that before a rule may take effect, the agency promulgating the rule must submit a rule report, which includes a copy of the rule, to each House of the Congress and to the Comptroller General of the United States. The EPA will submit a report containing this rule and other required information to the U.S. Senate, the U.S. House of Representatives, and the Comptroller General of the United States prior to publication of the rule in the **Federal Register**. A major rule cannot take effect until 60 days after it is published in the **Federal Register**. This action is not a ''major rule'' as defined by 5 U.S.C. 804(2). This rule will be effective April 5, 2005.

K. Judicial Review

Section 307 (b) (1) of the CAA indicates which Federal Courts of Appeal have venue for petitions of review of final actions by EPA. This section provides, in part, that petitions for review must be filed in the Court of Appeals for the District of Columbia Circuit (i) when the agency action consists of ''nationally applicable regulations promulgated, or final actions taken, by the Administrator,'' or (ii) when such action is locally or regionally applicable, if ''such action is based on a determination of nationwide scope or effect and if in taking such action the Administrator finds and publishes that such action is based on such a determination.''

This rule designating areas for the PM2.5 NAAQS is ''nationally applicable'' within the meaning of section 307(b)(1). This rule establishes designations for all areas of the United States for the PM2.5 NAAQS. At the core of this rulemaking is EPA's interpretation of the definition of nonattainment under section 107(d)(1) of the CAA. In determining which areas should be designated nonattainment (or conversely, should be designated attainment/unclassifiable), EPA used a set of nine technical factors that it applied consistently across the United States.

For the same reasons, the Administrator also is determining that the final designations are of nationwide scope and effect for the purposes of section 307(b)(1). This is particularly appropriate because in the report on the 1977 Amendments that revised section 307(b)(1) of the CAA, Congress noted that the Administrator's determination that an action is of ''nationwide scope or effect'' would be appropriate for any action that has ''scope or effect beyond a single judicial circuit.'' H.R. Rep. No. 95–294 at 323, 324, *reprinted* in 1977 U.S.C.C.A.N. 1402–03. Here, the scope and effect of this rulemaking extends to numerous judicial circuits since the designations apply to all areas of the country. In these circumstances, section 307(b)(1) and its legislative history calls for the Administrator to find the rule to be of ''nationwide scope or effect'' and for venue to be in the D.C. Circuit.

Thus, any petitions for review of final designations must be filed in the Court of Appeals for the District of Columbia Circuit within 60 days from the date final action is published in the **Federal Register**.

List of Subjects in 40 CFR Part 81

Environmental protection, Air pollution control, National parks, Wilderness areas.

Dated: December 17, 2004.

Michael O. Leavitt,

EPA Administrator.

■ For the reasons set forth in the preamble, 40 CFR Part 81, Subpart C is amended as follows:

PART 81—DESIGNATIONS OF AREAS FOR AIR QUALITY PLANNING PURPOSES

■ 1. The authority citation for part 81 continues to read as follows:

Authority: 42 U.S.C. 7401, *et seq.*

Subpart C—Section 107 Attainment Status Designations

■ 2. Section 81.300 is amended by revising paragraph (a) to read as follows:

§ 81.300 Scope.

(a) Attainment status designations as approved or designated by the Environmental Protection Agency (EPA) pursuant to section 107 of the CAA are listed in this subpart. Area designations are subject to revision whenever sufficient data becomes available to warrant a redesignation. Both the State and EPA can initiate changes to these designations, but any State redesignation must be submitted to EPA for concurrence. The EPA has replaced the national ambient air quality standards for particulate matter measured as total suspended particulate with standards measured as particulate matter with an aerodynamic diameter less than or equal to a nominal 10 micrometers (PM–10). Accordingly, area designations for PM–10 are included in the lists in subpart C of this part. However, the TSP area designations will also remain in effect until the Administrator determines that the designations are no longer necessary for implementing the maximum allowable increases in concentrations of particulate matter pursuant to section 163(b) of the CAA, as explained in paragraph (b) of this section. The EPA has also added national ambient air quality standards for fine particulate matter measured as particulate matter with an aerodynamic diameter less than or equal to a nominal 2.5 micrometers (PM2.5). Accordingly, area designations for PM2.5 are included in the lists in subpart C of this part.

The islands located in the South Central Coast Air Basin, including San Miguel, Santa Rosa, Santa Cruz, and San Nicolas.		
Ventura County (part)	.....	Unclassifiable/Attainment.
Anacapa and San Nicolas Islands.		
Great Basin Valleys Air Basin:		
Alpine County	.....	Unclassifiable/Attainment.
Inyo County (part)	.....	Unclassifiable/Attainment.
That portion of Inyo County that lies outside Hydrologic Unit Number 18090205.		
Mono County	.....	Unclassifiable/Attainment.
Coso Junction:		
Inyo County (part)	.....	Unclassifiable/Attainment.
That portion of Inyo County that lies inside Hydrologic Unit Number 18090205.		
Eastern Kern County:		
Kern County (part)	.....	Unclassifiable/Attainment.

CALIFORNIA.—PM2.5—Continued

Designated area	Designation [a]	
	Date [1]	Type
That portion of Kern County (with the exception of that portion in Hydrologic Unit Number 18090205 —the Indian Wells Valley) east and south of a line described as follows: Beginning at the Kern—Los Angeles County boundary and running north and east along the northwest boundary of the Rancho La Liebre Land Grant to the point of intersection with the range line common to Range 16 West and Range 17 West, San Bernardino Base and Meridian; north along the range line to the point of intersection with the Rancho El Tejon Land Grant boundary; then southeast, northeast, and northwest along the boundary of the Rancho El Tejon Grant to the northwest corner of Section 3, Township 11 North, Range 17 West; then west 1.2 miles; then north to the Rancho El Tejon Land Grant boundary; then northwest along the Rancho El Tejon line to the southeast corner of Section 34, Township 32 South, Range 30 East, Mount Diablo Base and Meridian; then north to the northwest corner of Section 35, Township 31 South, Range 30 East; then northeast along the boundary of the Rancho El Tejon Land Grant to the southwest corner of Section 18, Township 31 South, Range 31 East; then east to the southeast corner of Section 13, Township 31 South, Range 31 East; then north along the range line common to Range 31 East and Range 32 East, Mount Diablo Base and Meridian, to the northwest corner of Section 6, Township 29 South, Range 32 East; then east to the southwest corner of Section 31, Township 28 South, Range 32 East; then north along the range line common to Range 31 East and Range 32 East to the northwest corner of Section 6, Township 28 South, Range 32 East, then west to the southeast corner of Section 36, Township 27 South, Range 31 East, then north along the range line common to Range 31 East and Range 32 East to the Kern-Tulare County boundary.		
Indian Wells Valley:		
Kern County (part)	.....	Unclassifiable/Attainment.
That portion of Kern County that lies inside Hydrologic Unit Number 18090205.		
Western Mojave Desert and Antelope Valley:		
Los Angeles County (part)	.....	Unclassifiable
That portion of Los Angeles County which lies north and east of a line described as follows: Beginning at the Los Angeles—San Bernardino County boundary and running west along the Township line common to Township 3 North and Township 2 North, San Bernardino Base and Meridian; then north along the range line common to Range 8 West and Range 9 West; then west along the Township line common to Township 4 North and Township 3 North; then north along the range line common to Range 12 West and Range 13 West to the southeast corner of Section 12, Township 5 North and Range 13 West; then west along the south boundaries of Sections 12, 11, 10, 9, 8, and 7, Township 5 North and Range 13 West to the boundary of the Angeles National Forest which is collinear with the range line common to Range 13 West and Range 14 West; then north and west along the Angeles National Forest boundary to the point of intersection with the Township line common to Township 7 North and Township 6 North (point is at the northwest corner of Section 4 in Township 6 North and Range 14 West); then west along the Township line common to Township 7 North and Township 6 North; then north along the range line common to Range 15 West and Range 16 West to the southeast corner of Section 13, Township 7 North and Range 16 West; then along the south boundaries of Sections 13, 14, 15, 16, 17, and 18, Township 7 North and Range 16 West; then north along the range line common to Range 16 West and Range 17 West to the north boundary of the Angeles National Forest (collinear with the Township line common to Township 8 North and Township 7 North); then west and north along the Angeles National Forest boundary to the point of intersection with the south boundary of the Rancho La Liebre Land Grant; then west and north along this land grant boundary to the Los Angeles-Kern County boundary.		
San Bernardino County (part)	.....	Unclassifiable/Attainment.
That portion of San Bernardino County (with the exception of that portion in Hydrologic Unit Number 18090205) which lies north and east of a line described as follows: Beginning at the San Bernardino—Riverside County boundary and running north along the range line common to Range 3 East and Range 2 East, San Bernardino Base and Meridian; then west along the Township line common to Township 3 North and Township 2 North to the San Bernardino—Los Angeles County boundary; And that portion of San Bernardino County which lies south and west of a line described as follows: latitude 35 degrees, 10 minutes north and longitude 115 degrees, 45 minutes west.		
Trona:		
San Bernardino County (part)	.....	Unclassifiable/Attainment.
That portion of San Bernardino County that lies inside Hydrologic Unit Number 18090205.		
Coachella Valley:		
Riverside County (part)	.....	Unclassifiable/Attainment.

CALIFORNIA.—PM2.5—Continued

Designated area	Designation [a]	
	Date [1]	Type
That portion of Riverside County which lies to the east of a line described as follows: Beginning at the Riverside—San Diego County boundary and running north along the range line common to Range 4 East and Range 3 East, San Bernardino Base and Meridian; then east along the Township line common to Township 8 South and Township 7 South; then north along the range line common to Range 5 East and Range 4 East; then west along the Township line common to Township 6 South and Township 7 South to the southwest corner of Section 34, Township 6 South, Range 4 East; then north along the west boundaries of Sections 34, 27, 22, 15, 10, and 3, Township 6 South, Range 4 East; then west along the Township line common to Township 5 South and Township 6 South; then north along the range line common to Range 4 East and Range 3 East; then west along the south boundaries of Sections 13, 14, 15, 16, 17, and 18, Township 5 South, Range 3 East; then north along the range line common to Range 2 East and Range 3 East;, to the Riverside-San Bernardino County line: And that portion of Riverside County which lies to the west of a line described as follows: That segment of the southwestern boundary line of Hydrologic Unit Number 18100100 within Riverside County, further described as follows: Beginning at the Riverside-Imperial County boundary and running north along the range line common to Range 17 East and Range 16 East, San Bernardino Base and Meridian; then northwest along the ridge line of the Chuckwalla Mountains, through Township 8 South, Range 16 East and Township 7 South, Range 16 East, until the Black Butte Mountain, elevation 4504'; then west and northwest along the ridge line to the southwest corner of Township 5 South, Range 14 East; then north along the range line common to Range 14 East and Range 13 East; then west and northwest along the ridge line to Monument Mountain, elevation 4834'; then southwest and then northwest along the ridge line of the Little San Bernardino Mountains to Quail Mountain, elev. 5814'; then northwest along the ridge line to the Riverside-San Bernardino County line.		
Far Eastern Riverside and San Bernardino Counties:		
San Bernardino County (remainder)	.....	Unclassifiable/Attainment.
Riverside County (remainder)	.....	Unclassifiable/Attainment.
Imperial County:		
Imperial County	.....	Unclassifiable/Attainment.
San Diego County Tribal Area:		
San Diego County (part).		
La Posta Areas #1 and #2[b]	.....	Unclassifiable/Attainment.
Cuyapaipe Area[b]	.....	Unclassifiable/Attainment.
Manzanita Area[b]	.....	Unclassifiable/Attainment.
Campo Areas #1 and #2[b]	.....	Unclassifiable/Attainment.

[a] Includes Indian Country located in each county or area, except as otherwise specified.
[1] This date is 90 days after January 5, 2005, unless otherwise noted.
[b] The boundaries for these designated areas are based on coordinates of latitude and longitude derived from EPA Region 9's GIS database and are illustrated in a map entitled ''Southeastern San Diego County Unclassifiable/Attainment. Areas for the PM–2.5 NAAQS,'' dated December 10, 2004, including an attached set of coordinates. The map and attached set of coordinates are available at EPA's Region 9 Air Division office. The designated areas roughly approximate the boundaries of the reservations for these tribes, but their inclusion in this table is intended for the CAA planning purposes only and is not intended to be a federal determination of the exact boundaries of the reservations. Also, the specific listing of these areas in this table does not confer, deny, or withdraw Federal recognition of any of the tribes so listed nor any of the tribes not listed.

■ 7. In § 81.306, the table entitled ''Colorado—PM2.5'' is added to the end of the section to read as follows:

[FR Doc. 05–1 Filed 1–4–05; 8:45 am]
BILLING CODE 6560–50–P

Air and Radiation (OAR) is now nearing completion of the analytical work for the second prospective study. The AQMS met on February 19, 2010 [**Federal Register** Notice dated January 26, 2010 (75 FR 4070–4071)] to review technical documents pertaining to modeling of air quality for seven emissions scenarios: a 1990 baseline simulation; and simulations for 2000, 2010 and 2020 with and without the CAAA. Materials for the February 19 meeting are available on the Council Web site at *http://yosemite.epa.gov/sab/SABPRODUCT.NSF/MeetingCal/962D3C3D233888B085257695005098B5?OpenDocument.* The purpose of the March 15 teleconference meeting is to discuss and finalize the AQMS draft advisory report.

Technical Contacts: The Office of Air and Radiation technical contact for the Second Section 812 Benefit-Cost Analysis of the Clean Air Act is Mr. Jim DeMocker at (202) 564–1673 or *democker.jim@epa.gov*.

Availability of Meeting Materials: The AQMS draft advisory report and meeting agenda for the March 2010 teleconference will be posted to the Council Web site (*http://www.epa.gov/advisorycouncilcaa*) prior to the meeting. EPA draft documents provided to the AQMS are available at *http://www.epa.gov/oar/sect812/prospective2.html.*

Procedures for Providing Public Input: Interested members of the public may submit relevant written or oral information for the AQMS to consider on the topics of this advisory activity. *Oral Statements:* In general, individuals or groups requesting an oral presentation at a teleconference meeting will be limited to three minutes per speaker, with no more than a total of one hour for all speakers. Interested parties should contact Ms. Sanzone at the contact information provided above by March 10, 2010, to be placed on the public speaker list for the March 15, 2010 meeting. *Written Statements:* Written statements should be received in the SAB Staff Office by March 10, 2010, so that the information can be made available to the AQMS for their consideration prior to the meeting. Written statements should be supplied to Ms. Sanzone in the following formats: one hard copy with original signature and one electronic copy via e-mail (acceptable file format: Adobe Acrobat PDF, MS Word, WordPerfect, MS PowerPoint, or Rich Text files). Submitters are asked to provide electronic versions of each document submitted with *and* without signatures, because the SAB Staff Office does not publish documents with signatures on its Web sites.

Accessibility: For information on access or services for individuals with disabilities, please contact Ms. Sanzone at (202) 343–9697, or via e-mail at *sanzone.stephanie@epa.gov,* preferably at least ten (10) days prior to the meeting, to give EPA as much time as possible to process your request.

Dated: February 24, 2010.

Anthony Maciorowski,

Deputy Director, EPA Science Advisory Board Staff Office.

BILLING CODE 6560–50–P

ENVIRONMENTAL PROTECTION AGENCY

[FRL–9121–1]

Official Release of the MOVES2010 Motor Vehicle Emissions Model for Emissions Inventories in SIPs and Transportation Conformity

AGENCY: Environmental Protection Agency (EPA).

ACTION: Notice of availability.

SUMMARY: EPA is approving and announcing the availability of the Motor Vehicle Emissions Simulator model (MOVES2010) for official use outside of California. MOVES2010 is the state-of-the-art upgrade to EPA's modeling tools for estimating emissions from cars, trucks, motorcycles, and buses, based on analysis of millions of emission test results and considerable advances in the Agency's understanding of vehicle emissions.

Today's notice approves the use of MOVES2010 in official State implementation air quality plan (SIP) submissions to EPA and for certain transportation conformity analyses outside of California. This notice starts a two-year grace period before the MOVES2010 emission model is required to be used in new regional emissions analyses for transportation conformity determinations outside of California. EPA is not approving MOVES2010 for project-level transportation conformity hot-spot analyses at this time; the Agency will approve the model for such analyses in the near future in a separate **Federal Register** notice when guidance is finalized.

EPA strongly encourages areas to use the interagency consultation process to examine how MOVES2010 will affect future transportation plan and transportation improvement program (TIP) conformity determinations so, if necessary, SIPs and motor vehicle emissions budgets can be revised with MOVES2010 or transportation plans and TIPs can be revised as appropriate prior to the end of the MOVES2010 conformity grace period. EPA also encourages State and local air agencies to consider how the release of MOVES2010 will affect analyses supporting SIP submissions under development.

DATES: EPA's approval of the MOVES2010 emissions model for SIPs and regional emissions analyses for transportation conformity is effective March 2, 2010. As discussed further below, today's approval also starts a two-year transportation conformity grace period which ends on *March 2, 2012,* after which MOVES2010 is required to be used for new regional emissions analyses for transportation conformity.

FOR FURTHER INFORMATION CONTACT: For technical model questions regarding the official release or use of MOVES2010, please e-mail EPA at *mobile@epa.gov* or call (734) 214–4636. For questions about SIPs, contact Rudy Kapichak at *Kapichak.Rudolph@epa.gov* or (734) 214–4574. For transportation conformity questions, contact Meg Patulski at *Patulski.Meg@epa.gov* or (734) 214–4842.

SUPPLEMENTARY INFORMATION: The contents of this notice are as follows:

Availability of MOVES2010 and Support Materials

Copies of the official version of the MOVES2010 model, along with user guides and supporting documentation, are available on EPA's MOVES Web site: *http://www.epa.gov/otaq/models/moves/index.htm.*

Guidance on how to apply MOVES2010 for SIPs and transportation conformity purposes, including "Policy Guidance on the Use of MOVES2010 for State Implementation Plan Development, Transportation Conformity, and Other Purposes" (EPA–420–B–09–046, December 2009) and "Technical Guidance on the Use of MOVES2010 for Emission Inventory Preparation in State Implementation Plans and Transportation Conformity" (EPA–420–B–09–042, December 2009) can be found on the EPA's transportation conformity Web site at: *http://www.epa.gov/otaq/stateresources/transconf/policy.htm.*

EPA will continue to update this Web site as other MOVES support materials and guidance are developed.

Individuals who wish to receive EPA announcements related to the MOVES2010 model should subscribe to the EPA–MOBILENEWS e-mail listserver. To subscribe to the EPA–MOBILENEWS listserver, send a blank e-mail to EPA at *join-EPA-MOBILENEWS@lists.epa.gov.* Your e-mail address will then be added to the list of subscribers and a confirmation message will be sent to your e-mail address. Whenever a message is posted to the EPA–MOBILENEWS listserver by the listserver owner (the Assessment and Standards Division of EPA's Office of Transportation and Air Quality), a copy of that message will be sent to every person who has subscribed. You can remove yourself from the list by sending a blank e-mail to EPA at *leave-EPA-MOBILENEWS@lists.epa.gov.* This e-mail must be sent from the same e-mail address that you used to subscribe. For more information about the EPA–MOBILENEWS listserver, visit EPA's Web site at *http://www.epa.gov/otaq/models/mobilelist.htm.*

I. What Is MOVES2010?

MOVES2010 is the state-of-the-art upgrade to EPA's modeling tools for estimating emissions from highway vehicles, based on analysis of millions of emission test results and considerable advances in the Agency's understanding of vehicle emissions. Today's notice approves MOVES2010 as EPA's official motor vehicle emissions factor model for estimating volatile organic compounds (VOCs), nitrogen oxides (NO_X), carbon monoxide (CO), direct particulate matter (PM_{10} and $PM_{2.5}$) and other precursors from cars, trucks, buses, and motorcycles by State and local agencies for SIP purposes and regional emissions analyses for transportation conformity outside of California. For these purposes, MOVES2010 replaces the previous emissions model, MOBILE6.2, which was released in 2004 (69 FR 28830).[1]

MOVES2010 improves upon MOBILE6.2 in several key respects. For example, MOVES2010 is based on a review of the vast amount of in-use vehicle data collected and analyzed since the release of MOBILE6.2, including millions of emissions measurements from light-duty vehicles. Analysis of this data has enhanced EPA's understanding of how on-road mobile sources contribute to emissions inventories, and has also improved the agency's understanding of the relative effectiveness of various control strategies. MOVES2010 has a database-centered design that allows users much greater flexibility in organizing input and output data. This structure also allows EPA to update emissions data incorporated in MOVES2010 more easily.

MOVES2010 includes the capability to estimate vehicle exhaust and evaporative emissions as well as brake wear and tire wear emissions for criteria pollutants and precursors. However, MOVES2010 does not include the capability to estimate emissions of re-entrained road dust. To estimate emissions from re-entrained road dust, practitioners should continue to use the latest approved methodologies.[2]

II. SIP Policy for MOVES2010

EPA has articulated its policy regarding the use of MOVES2010 in SIP development in its "Policy Guidance on the Use of MOVES2010 for State Implementation Plan Development, Transportation Conformity, and Other Purposes" (EPA–420–B–09–046, December 2009). Today's notice highlights certain aspects of the guidance, but State and local governments should refer to the guidance for more detailed information on how and when to use MOVES2010 in reasonable further progress SIPs, attainment demonstrations, maintenance plans, inventory updates, and other SIP submission requirements.

Although MOVES2010 should be used in SIP development as expeditiously as possible, EPA also recognizes the time and effort that States have already undertaken in SIP development using MOBILE6.2. SIPs that EPA has already approved are not required to be revised solely based on existence of the new model. States that have already submitted SIPs or will submit SIPs shortly after EPA's approval of MOVES2010 are not required to revise these SIPs simply because a new motor vehicle emissions model is now available. States can choose to use MOVES2010 in these SIPs, for example, if it is determined that it is appropriate to update motor vehicle emissions budgets ("budgets") with the MOVES2010 model for future conformity determinations. However, EPA does not believe that a State's use of MOBILE6.2 should be an obstacle to EPA approval for SIPs that have been or will soon be submitted, assuming that such SIPs are otherwise approvable and significant SIP work has already occurred (*e.g.,* attainment modeling for an attainment SIP has already been completed with MOBILE6.2). It would be unreasonable in such cases to require States to revise these SIPs with MOVES2010 since significant work has already occurred, and EPA intends to act on these SIPs in a timely manner.

States should use MOVES2010 where SIP development is in its initial stages or hasn't progressed far enough along that switching to MOVES2010 would create a significantly adverse impact on State resources. For example, States (except California) that will be developing on-road mobile source inventories for 2006 24-hour $PM_{2.5}$ NAAQS SIPs should base those inventories on MOVES2010. EPA designated nonattainment areas for this NAAQS on November 13, 2009 (74 FR 58688), which should give State and local agencies time to incorporate MOVES2010 into SIP submissions for this NAAQS. MOVES2010 should be incorporated into these and other SIPs, as appropriate, since MOVES2010 emissions estimates are based on the best information currently available, as required by Clean Air Act section 172(c)(3) and 40 CFR 51.112(a)(1).

III. Transportation Conformity Policy for MOVES2010

EPA is establishing a two-year grace period before MOVES2010 is required for new transportation plan and TIP conformity determinations and regional emissions analyses. This grace period begins today and ends March 2, 2012. The remainder of this section describes how the transportation conformity grace period was determined and summarizes how it will be implemented, including those circumstances when the grace period could be shorter than two years. However, for complete explanations of how MOVES2010 is to be implemented for transportation conformity, including details about using MOVES2010 during the grace period, refer to "Policy Guidance on the Use of MOVES2010 for State Implementation Plan Development, Transportation Conformity, and Other Purposes" (EPA–420–B–09–046, December 2009). EPA coordinated closely with the U.S.

[1] Today's notice does not affect emissions model requirements within California, where the EMFAC2007 emissions model is currently approved for SIP purposes and for regional emissions analyses and CO hot-spot analyses for transportation conformity (73 FR 3464).

[2] *See* EPA's notice of availability published in the **Federal Register** on May 19, 2004, 69 FR 28830–28832. Also see EPA's memoranda: "Policy Guidance on the Use of the November 1, 2006, Updated to AP–42 for Re-entrained Road Dust for SIP Development and Transportation Conformity," August 2, 2007; and "Policy Guidance on the Use of MOBILE6.2 and the December 2003 AP–42 Method for Re-entrained Road Dust for SIP Development and Transportation Conformity," February 24, 2004. These documents are available on EPA's Web site at: *http://www.epa.gov/otaq/stateresources/transconf/policy.htm.*

Department of Transportation (DOT) in the establishment of the grace period.

A. Length of Conformity Grace Period

Transportation conformity is a Clean Air Act requirement to ensure that Federally supported highway and transit activities are consistent with ("conform to") the SIP. Conformity to a SIP means that a transportation activity will not cause or contribute to new air quality violations; worsen existing violations; or delay timely attainment of the national ambient air quality standards or any interim milestone. Transportation conformity applies in nonattainment and maintenance areas for transportation-related pollutants: ozone, carbon monoxide (CO), $PM_{2.5}$, PM_{10}, and nitrogen dioxide.

The transportation conformity rule (40 CFR parts 51 and 93) requires that conformity determinations be based on the latest motor vehicle emissions model approved by EPA. Section 176(c)(1) of the Clean Air Act states that "* * * [t]he determination of conformity shall be based on the most recent estimates of emissions, and such estimates shall be determined from the most recent population, employment, travel, and congestion estimates * * *." When EPA approves a new emissions model such as MOVES2010, a grace period is established before the model is required for conformity analyses. The conformity rule provides for a grace period for new emissions models of between three and 24 months (40 CFR 93.111(b)(1)).

EPA articulated its intentions for establishing the length of a conformity grace period in the preamble to the 1993 transportation conformity rule (58 FR 62211):

> EPA and DOT will consider extending the grace period if the effects of the new emissions model are so significant that previous SIP demonstrations of what emission levels are consistent with attainment would be substantially affected. In such cases, States should have an opportunity to revise their SIPs before MPOs [metropolitan planning organizations] must use the model's new emissions factors.

In consultation with DOT, EPA must consider many factors when establishing a grace period for conformity determinations, including the degree of change in emissions models and the effects of the new model on the transportation planning process (40 CFR 93.111(b)(2)).

Upon consideration of all of these factors, EPA is establishing a two-year grace period, which begins today and ends on March 2, 2012, before MOVES2010 is required to be used for regional transportation conformity purposes. During this grace period, areas should use the interagency consultation process to examine the impact of using MOVES2010 in their future transportation plan and TIP conformity determinations and regional emissions analyses.

B. Circumstances When Grace Period Will Be Shorter Than Two Years

The grace period will be shorter than two years for a given pollutant if an area revises its SIP and budgets with MOVES2010, and such budgets become applicable for regional conformity purposes prior to the end of the two-year grace period. In this case, the new regional emissions analysis must use MOVES2010 if the conformity determination is based on a MOVES2010-based budget.

Areas that are designated nonattainment or maintenance for multiple pollutants may rely on both MOVES2010 and MOBILE6.2 to determine conformity for different pollutants during the grace period. For example, if an area revises a previously submitted (but not approved) MOBILE6.2-based PM_{10} SIP with MOVES2010 and EPA finds these revised MOVES2010 budgets adequate for conformity, such budgets would apply for conformity on the effective date of the **Federal Register** notice announcing EPA's adequacy finding. In this example, if an area was in nonattainment for PM_{10} and ozone, the MOVES2010 grace period would end for PM_{10} once EPA found the new MOVES2010-based SIP budgets adequate. However, MOBILE6.2 could continue to be used for ozone conformity determinations until the end of the MOVES2010 grace period.[3] EPA Regional Offices should be consulted for questions regarding such situations in multi-pollutant areas.

In addition, if an area revises a previously approved SIP using MOVES2010, the revised MOVES2010 budgets would be used for conformity purposes once EPA approves the MOVES2010 SIP revision, in most cases. In general, submitted SIPs cannot supersede approved budgets until they are approved. However, 40 CFR 93.118(e)(1) allows an approved budget to be replaced by an adequate budget if EPA's approval of the initial budgets specifies that the budgets being approved may be replaced in the future by new adequate budgets. This flexibility has been used in limited situations in the past, such as during the transition from MOBILE5 to MOBILE6. In such cases, the MOVES2010-based budgets would be used for conformity purposes once they have been found adequate, if requested by the State in its SIP submission and specified in EPA's SIP approval. States should consult with their EPA Regional Office to determine if this flexibility applies to their situation.

C. Use of MOVES2010 During the Grace Period

During the conformity grace period, areas should use the interagency consultation process to examine how MOVES2010 will impact their future transportation plan and TIP conformity determinations and any regional emissions analyses. Areas should carefully consider whether the SIP and budgets should be revised with MOVES2010 or if transportation plans and TIPs should be revised before the end of the conformity grace period, since doing so may be necessary to ensure conformity in the future.

Regional emissions analyses that are started during the grace period can use either MOBILE6.2 or MOVES2010. When the grace period ends on March 2, 2012, MOVES2010 will become the only approved motor vehicle emissions model for regional emissions analyses for transportation conformity in States other than California. In general, this means that all new transportation plan and TIP conformity determinations started after the end of the grace period must be based on MOVES2010, even if the SIP is based on MOBILE6.2.

Finally, the conformity rule provides some flexibility for regional emissions analyses that are started before the end of the grace period. Analyses that begin before or during the grace period may continue to rely on MOBILE6.2. The interagency consultation process should be used if it is unclear if a MOBILE6.2-based analysis was begun before the end of the grace period. If you have questions about which model should be used in your conformity determination, you can also consult with your EPA Regional Office.

IV. Future Notice Approving MOVES2010 for Project-level Conformity Hot-spot Analyses

Today's notice does not approve MOVES2010 for use in transportation conformity hot-spot analyses in $PM_{2.5}$, PM_{10}, and CO nonattainment and

[3] In this example, such an area would use MOVES2010 to develop a regional emissions analysis for comparison to the revised MOVES2010-based budgets (*e.g.,* PM_{10} and NOx budgets). The regional emissions analysis for ozone could be based on MOBILE6.2 for the VOC and NOx budgets in the ozone SIP for the remainder of the conformity grace period.

maintenance areas.[4] EPA will approve MOVES2010 for these purposes, and establish a separate two-year conformity grace period, in a subsequent **Federal Register** notice. Details on how EPA intends to implement MOVES2010 for quantitative CO, $PM_{2.5}$, and PM_{10} hot-spot analyses can be found in "Policy Guidance on the Use of MOVES2010 for State Implementation Plan Development, Transportation Conformity, and Other Purposes" (EPA–420–B–09–042, December 2009).

Dated: February 24, 2010.

Margo Tsirigotis Oge,

Director, Office of Transportation and Air Quality.

EXPORT-IMPORT BANK OF THE UNITED STATES

Notice of Open Meeting of the Advisory Committee of the Export-Import Bank of the United States (Ex-Im Bank)

SUMMARY: The Advisory Committee was established by Public Law 98–181, November 30, 1983, to advise the Export-Import Bank on its programs and to provide comments for inclusion in the reports of the Export-Import Bank of the United States to Congress.

TIME AND PLACE: Friday, March 12, 2010 beginning at 2:30 p.m. The meeting will be held in the Palladian Room at the Onmi Shoreham Hotel, 2500 Calvert Street, NW., Washington, DC 20008.

Agenda: Agenda items include a briefing on the status of the 2010 Advisory Committee's Subcommittees and the challenges for 2010.

Public Participation: The meeting will be open to public participation, and the last 10 minutes will be set aside for oral questions or comments. Members of the public may also file written statement(s) before or after the meeting. If any person wishes auxiliary aids (such as a sign language interpreter) or other special accommodations, please contact, prior to March 3, 2010, Susan Houser, Room 1273, 811 Vermont Avenue, NW., Washington, DC 20571, *Voice:* (202) 565–3232 or TDD (202) 565–3377.

FOR FURTHER INFORMATION CONTACT: For further information, contact Susan Houser, Room 1273, 811 Vermont Ave., NW., Washington, DC 20571, (202) 565–3232.

Jonathan Cordone,

Senior Vice President and General Counsel.

FARM CREDIT ADMINISTRATION

Farm Credit Administration Board; Sunshine Act; Regular Meeting

AGENCY: Farm Credit Administration.

SUMMARY: Notice is hereby given, pursuant to the Government in the Sunshine Act (5 U.S.C. 552b(e)(3)), of the regular meeting of the Farm Credit Administration Board (Board).

DATE AND TIME: The regular meeting of the Board will be held at the offices of the Farm Credit Administration in McLean, Virginia, on March 11, 2010, from 9 a.m. until such time as the Board concludes its business.

FOR FURTHER INFORMATION CONTACT: Roland E. Smith, Secretary to the Farm Credit Administration Board, (703) 883–4009, TTY (703) 883–4056.

ADDRESSES: Farm Credit Administration, 1501 Farm Credit Drive, McLean, Virginia 22102–5090.

SUPPLEMENTARY INFORMATION: This meeting of the Board will be open to the public (limited space available). In order to increase the accessibility to Board meetings, persons requiring assistance should make arrangements in advance. The matters to be considered at the meeting are:

Open Session

A. Approval of Minutes

- February 24, 2010

B. New Business

Environmental Protection Agency

40 CFR Part 81

Air Quality Designations for the Fine Particles (PM2.5) National Ambient Air Quality Standards—Supplemental Amendments; Final Rule

ENVIRONMENTAL PROTECTION AGENCY

40 CFR Part 81

[OAR–2003–0061; FRL–7896–8]

RIN–2060–AM04

Air Quality Designations for the Fine Particles (PM2.5) National Ambient Air Quality Standards—Supplemental Amendments

AGENCY: Environmental Protection Agency (EPA).

ACTION: Final rule; supplemental amendments.

SUMMARY: On January 5, 2005, EPA promulgated air quality designations for all areas for the national ambient air quality standards (NAAQS) for fine particles (*i.e.* particles less than 2.5 microns in diameter, also known as PM2.5) (70 FR 944). We designated 47 areas composed of 224 counties and the District of Columbia as nonattainment. We designated 5 areas comprised of 7 counties as unclassifiable. We designated the remaining counties in the United States as attainment/unclassifiable. We based the designations in the January 5, 2005, final rule on air quality monitoring data from the 3-year period of 2001 to 2003. In that action, we provided that these designations would be effective 90 days from the date of publication in the **Federal Register**, which is April 5, 2005. Because the designations occurred at the end of 2004, we indicated our desire to consider 2004 data where feasible in order to evaluate attainment status based upon data from the 3-year period of 2002 to 2004. We explained that we would consider any complete, quality-assured, and certified 2004 PM2.5 data submitted by any State to EPA by February 22, 2005, if such data indicated that a change in the designation for the entire area would be appropriate.

In the January 5, 2005, action, we stated that if EPA agreed that a change in the designation was appropriate based upon the inclusion of 2004 data, then EPA would withdraw the initial designation for the area and issue a designation that reflected the consideration of the new data before the April 5, 2005, effective date. Today's action addresses areas for which States have submitted complete, quality-assured, and certified PM2.5 air quality data for 2004, and it modifies the designation status to attainment for eight areas we originally designated as nonattainment and for four areas we originally designated as unclassifiable. This action also includes technical corrections related to boundary descriptions for a few areas included in the January 5, 2005, action. The EPA has received a number of other petitions in connection with the PM2.5 designations pertaining to issues other than inclusion of 2004 data as a basis for changing the designation prior to the effective date. The EPA is not responding to those petitions in this document and will be evaluating and responding to those petitions separately.

DATES: Effective upon April 5, 2005.

ADDRESSES: The EPA has established a docket for this action under Docket ID No. OAR–2003–0061. All documents in the docket are listed in the EDOCKET index at *http://www.epa.gov/edocket*. Although listed in the index, some information is not publicly available, *i.e.*, Confidential Business Information (CBI) or other information whose disclosure is restricted by statute. Certain other material, such as copyrighted material, is not placed on the Internet and will be publicly available only in hard copy form. Publicly available docket materials are available either electronically in the EDOCKET or in hard copy at the Docket, EPA/DC, EPA West, Room B102, 1301 Constitution Ave., NW., Washington, DC. The Public Reading Room is open from 8:30 a.m. to 4:30 p.m. Monday through Friday, excluding legal holidays. The telephone number for the public Reading Room is (202) 566–1744, and the telephone number for the Office of Air and Radiation Docket and Information Center is (202) 566–1742. In addition, we have placed a copy of the rule and a variety of materials regarding designations on EPA's designation Web site at: *http://www.epa.gov/oar/oaqps/particles/designations/index.htm* and on the Tribal Web site at: *http://www/epa.gov/air/tribal*.

Table of Contents

The following is an outline of the Preamble.

I. What Is the Purpose of Today's Action?

On January 5, 2005, EPA promulgated air quality designations for all areas in the United States for the NAAQS for PM2.5 (70 FR 944), in accordance with section 107(d) of the Clean Air Act (CAA). The list of areas in each State, the boundaries of each area, and the designation of each area, appear in a table at the end of that action. The purpose of today's action is to modify the PM2.5 designation for a number of areas that we designated nonattainment or unclassifiable in the January 5, 2005 action, and to make certain technical corrections to the table of areas described in 40 CFR part 81.

The January 5, 2005, PM2.5 designations were based on air quality data for 2001 through 2003. We designated 47 areas comprised of 224 counties and the District of Columbia were designated as nonattainment. We designated 5 areas comprised of 7 counties as unclassifiable. We designated the remaining counties in the United States as attainment/unclassifiable. We based the designations in the January 5, 2005, action on air quality monitor data from the 3-year period of 2001 to 2003. The action provided that these designations would be effective 90 days from the date of publication (*i.e.* April 5, 2005).

Because the designation process occurred so close to the end of the 2004 calendar year, EPA indicated that we would consider any complete, quality-assured, and certified PM2.5 data for 2004 submitted by any State by February 22, 2005, if such data indicated that the attainment status for the entire area, based on 2002–2004 data, would differ from the status indicated in the January 5 action. In other words, we indicated that the agency would consider changing the designation status of an area from nonattainment to attainment, or unclassifiable to attainment, if *each* monitor in the initially designated area had air quality data for the 2002–2004 period below the level of the standards.

The EPA received complete, quality-assured, and certified air quality data for 2004 from a number of States prior to February 22, 2005. Based on our evaluation of this data, in today's action, EPA is changing the designation status from nonattainment to attainment for eight areas, and from unclassifiable to attainment for four areas. Today's modifications to the initial designations for these areas do not represent ''redesignations'' because these changes are being made prior to the effective date of the initial PM2.5 designations. We are making these changes to reflect the most recent 3 years of complete, quality-assured, and certified data that are available prior to the effective date of the designations. After April 5, 2005, any change in the PM2.5 designation status for an area, other than those that might result from a petition for reconsideration or error correction, would be subject to the redesignation provisions of section 107(d)(3) of the CAA.

In the January 5, 2005, action, we also stated that if certified 2004 data indicated a violation of the standard in an area we initially designated as attainment based on 2001–2003 data, EPA would evaluate the reason for the violation and determine the appropriate course of action, including the possibility of redesignation to nonattainment. No States submitted certified 2004 data by February 22, 2005, to indicate that the status of any area should change from attainment or unclassifiable to nonattainment. The EPA has committed to evaluate all 2004 data for areas initially designated as unclassifiable. Under existing regulations, States are required to certify air quality data for 2004 by July 1, 2005. At that time, EPA will evaluate whether a change of designation for an unclassifiable area is appropriate.

II. Designation Decisions Based on 2002–2004 Data

Areas changing from nonattainment to attainment based on 2002–2004 data. A number of States, including AL, CA, GA, IN, KY, OH, PA, TN, and WV, submitted certified 2004 air quality monitoring data to EPA by February 22, 2005. (All correspondence from States related to this action can be found in docket OAR–2003–0061 for this action.) Based upon our technical evaluation of the certified 2004 data provided by these States, we have determined that the nonattainment designation for seven areas listed in the January 5 action (based on 2001–2003 data) should be changed to attainment (based on 2002–

2004 data). In each of these areas, all PM2.5 monitors have complete, quality-assured, and certified data below the level of the PM2.5 standards for the 2002–2004 period. These seven areas are:

—Athens, Georgia (Clarke county);
—Elkhart, Indiana (Elkhart and St. Joseph's counties);
—Lexington, Kentucky (Fayette and Mercer counties);
—Marion county, WV (Marion, Monangalia, and Harrison counties);
—San Diego, California (San Diego county);
—Toledo, Ohio (Lucas and Wood counties); and
—Youngstown, OH-PA (Columbiana, Mahoning, and Trumbull counties, Ohio; Mercer county, Pennsylvania).

(A summary of the air quality data for these areas is included in the technical support document for this action. Comprehensive information for these areas is available from EPA's Air Quality Subsystem at: *http://www.epa.gov/ttn/airs/airsaqs/index.htm*.)

Areas changing from unclassifiable to attainment based on 2002–2004 data. In addition, we have determined that for four areas the unclassifiable designation in the January 5 action (based on 2001–2003 data) should now be changed to attainment (based on 2002–2004 data). In each of these areas, all PM2.5 monitors have complete, quality-assured, and certified data below the level of the PM2.5 standards for the 2002–2004 period. These four areas are:

—Dekalb county, Alabama;
—Gadsden, Alabama (Etowah county);
—McMinn county, Tennessee; and
—Muncie, Indiana (Delaware county).

(A summary of the air quality data for these areas is included in the technical support document for this action. Comprehensive information for these areas is available from EPA's Air Quality Subsystem at: *http://www.epa.gov/ttn/airs/airsaqs/index.htm*.)

For all of the areas changing from either nonattainment or unclassifiable to attainment based upon the consideration of 2004 data, EPA has determined that it is appropriate to revise the initial designation announced in the January 5, 2005, action before the April 5, 2005, effective date. The EPA believes that the specific redesignation requirements of the CAA, including those set forth in section 107(d)(3)(E), do not apply until after the effective date of a designation. The EPA has concluded that, where possible, inclusion of 2004 data results in the appropriate initial designation. Subsequent changes to the designation of these or other areas may require compliance with the statutory provisions governing the formal redesignation process.

Requests to change individual counties to attainment. The EPA received requests from a number of States to change the status of a selected county within a larger nonattainment area from nonattainment to attainment based upon 2004 data. For five counties in four nonattainment areas (see table below), States submitted certified 2004 data showing that the 2002–2004 value for all monitors in the specific county at issue is below the level of the PM2.5 annual standard. In each of these situations, however, there are other monitors in the larger nonattainment area identified in the January 5, 2005 action which continue to violate the annual standard based on 2002–2004 data. The following table lists the State and county in question, the associated nonattainment area, and the other violating county in the area.

State	County	PM2.5 nonattainment area	Other county in area violating with 2002–2004 data
Indiana	Lake	Chicago	Cook County, IL
Indiana	Vanderburgh	Evansville	Dubois County, IN
Michigan	Monroe	Detroit	Wayne County, IL
Ohio	Scioto, Lawrence	Huntington, WV-OH	Cabell County, WV

The EPA indicated in the January 5 action that we would make changes in status from nonattainment to attainment based on certified 2004 data *only* for entire areas in which all PM2.5 monitors were attaining: ''If inclusion of 2004 data causes an area to change from nonattainment to attainment, EPA will change the designation if every county in the area is neither monitoring a violation of the standards nor contributing to a violation of the standards in another nearby area.'' In addition, EPA has examined the data and concluded that each of these counties continues to contribute to the overall air quality problem in the larger nonattainment area. As explained in the January 5, 2005 action, EPA has designated as nonattainment not only those counties with violating monitors, but also those nearby counties that contribute to the problem at the violating monitor. For these reasons, EPA is not changing the designation status for Lake and Vanderburgh Counties in Indiana, Monroe County in Michigan, and Scioto and Lawrence Counties in Ohio. The technical support document for this action includes additional discussion on each of these individual counties and nonattainment areas.

Also, EPA received a number of petitions from States and local governments that did not meet our request for submission of 2004 data indicating that a change of designation was appropriate for the entire area. In general, these petitions pertained to the degree of contribution to nonattainment of one or more counties within a nonattainment area or to the boundaries of specific nonattainment areas. The EPA is evaluating these petitions and intends to respond to them separately at a later date.

Chattanooga, TN request to invalidate multiple monitoring samples and change status to attainment. The Chattanooga-Hamilton County Air Pollution Control Bureau and the State of Georgia have submitted requests to EPA to invalidate samples for 25 days at monitors in Hamilton County, TN and Walker County, GA. They based their requests on claims that these sites were impacted by various fire events occurring in locations such as Kansas, Alaska, and Canada. Chattanooga claimed that if all such days were invalidated, then the Hamilton County, TN monitors would have incomplete data and could not remain designated as nonattainment. Georgia contended that if these samples were invalidated, the Walker County, GA monitor would then attain the standards. In addition, Georgia has maintained that if Walker County attains the standard, then the status for Catoosa County should be changed to attainment because the State claims its contribution to nonattainment does not extend to Hamilton County, TN. The EPA has concluded that Catoosa County contributes to both Hamilton and Walker Counties based upon evaluation of the factors applied

by EPA in the initial designation decision (particularly population, commuting, and emissions) as discussed in the original technical support document.

We have reviewed the data for the 25 days in question and the supporting information provided by local and State agencies for the Chattanooga area. Previously, EPA disapproved the request to invalidate 10 days in 2002. For the 15 days in 2003 and 2004 requested by Chattanooga to be invalidated due to fire impacts, EPA has determined that there is insufficient evidence to show impacts from the fire events for at least 7 of these days, and is disapproving the requests to invalidate air quality data for those days. This determination is based on EPA's review of the supporting information provided to EPA, as well as additional analyses conducted by EPA. These analyses include back trajectories and a review of chemical composition data for the area, and they are available in the technical support document and docket for this action.

The EPA has determined that it is not necessary to reach a final conclusion with respect to the remaining 8-flagged days. Even if it were appropriate to invalidate the data from all of the remaining days, the monitor in Hamilton County, TN would still violate the PM2.5 standards for 2002–2004 with a design value of 15.4. Assuming invalidation of all 7 days, the monitor in Walker County, GA would attain the standard at 14.8. However, even though the Walker County monitor would be below the level of the standard, we continue to conclude that Walker County contributes to the nonattainment problem at the Hamilton County, TN monitor, thus requiring the inclusion of that county in the nonattainment area.

Thus, even if it was appropriate to invalidate all of the remaining 8-flagged days, EPA has determined that at least one county in the Chattanooga nonattainment area would continue to have a violating monitor. As stated in the January 5, 2005, action, we indicated that it might be appropriate to change the nonattainment designation of an area only if all monitors in the area show attainment. Because there is a continuing violation at one monitor in the area, and because there is continued contribution from the other counties to the violating monitor, EPA has determined that the area still would violate the standard even if all additional flagged days were invalidated. Moreover, any uncertainty concerning the possible invalidation of the remaining flagged days is not an appropriate basis for designating this area unclassifiable. That designation is reserved for those areas where EPA lacks sufficient information upon which to make a judgment whether or not the area is attaining the PM2.5 NAAQS. In this instance, given that invalidation of the remaining flagged days would not change the outcome, the area does not meet the NAAQS. For this reason, EPA is not modifying the nonattainment status of Hamilton County in Tennessee or Walker or Catoosa Counties in Georgia.

Columbus, GA-AL: Request for spatial averaging and request for attainment based on 2002–2004 data.

Any State or States requesting spatial averaging of PM2.5 monitoring sites must demonstrate that the sites meet several criteria as described in EPA regulations (40 CFR part 58.). First, the annual mean for each site must be within 20 percent of the annual mean calculated with spatial averaging. Second, the sites must show ''similar day-to-day variability'' (*e.g.*, 0.60 correlation). Third, the States must demonstrate that the sites are affected by the same emissions sources. Fourth, the States must provide adequate notice to the public of the proposed change in the monitoring plan and potential effect on attainment status, including a public hearing and opportunity for public comment.

In June 2004, the States of Georgia and Alabama submitted proposed changes to their monitoring plans to conduct spatial averaging for three monitoring sites in the Columbus, GA-AL area (two in Muscogee County, GA and one in Russell County, AL). In November 2004, EPA denied the request for spatial averaging on the basis that: (1) the submittal did not provide a basis for a 3-site community monitoring zone, and (2) the information did not demonstrate that all monitors were impacted by similar emissions sources. The letter also questioned the validity of several samples collected at the Russell county site during 2001 and 2002.

In December 2004, both States submitted revised monitoring plans requesting spatial averaging for the two downtown monitoring sites, one in Muscogee County, GA and one in Russell County, AL. In February 2005, both States submitted certified 2004 data for the two sites in question, and they also requested a change in status from nonattainment to attainment for the area, provided that EPA approved their pending spatial averaging request and that 2002–2004 data for the two sites could be averaged.

The EPA has conducted an extensive technical review of the information provided by both States to support the most recent spatial averaging proposals. Based on our review of a number of factors, we are approving the spatial averaging request. We also have determined that when 2002–2004 air quality data for the two sites are averaged, the Columbus, GA-AL metropolitan area now attains the PM2.5 standards. The spatial average for 2002–2004 is just under the standard at a level of 15.04.

In evaluating the spatial averaging proposals, EPA considered a number of factors in accordance with the PM2.5 NAAQS and PM2.5 monitoring regulations. The two monitors (one operated in Phenix City by AL and one in Columbus by GA) are less that 2 km apart. Both monitors are located in the inner city and are influenced by similar emission sources. The 3-year design value for each site is within ±2 percent of the new approved spatial average design value of 15.04. Furthermore, the monitors exhibit similar day-to-day variability indicated by a 0.85 correlation of 24-hr concentrations.

However, EPA also notes that annual concentrations at the two monitors are trending upward, with each site recording its highest annual average concentration in 2004. The 2004 average for these monitors is 15.4 $\mu g/m^3$. The EPA also notes that the monitors exhibit the highest disparity in their 24-hr concentrations during the 1st calendar quarter. Therefore, EPA will continue to monitor the PM2.5 measurements particularly during the winter period to ensure that we have a continuing understanding of any air quality changes that may occur in the future.

Therefore, for the above reasons and others discussed in the technical support document, EPA is approving the December 2004 2-site spatial averaging plan for the Columbus, GA-AL nonattainment area in today's action. It is therefore appropriate to change the designation of Muscogee County, GA and Russell County, AL from nonattainment to attainment. Please refer to the technical support document for more detailed information on EPA's review of the spatial averaging plan for this area.

III. Technical Corrections for Area Boundaries

In today's rule, EPA is also making minor technical corrections to certain attainment area boundary descriptions included in the January 5 action. Technical corrections for boundaries listed in 40 CFR part 81 are included for the following areas: (1) The State of Louisiana to correct the listings for air quality control region 106, (2) the boundary description for Placer County,

CA, (3) a change to the boundary description for Randolph County, IL to change Baldwin Village to Baldwin Township, and (4) the boundary description for Gallia County, OH to remove Addison Township and to include Cheshire Township. These corrections are being made to provide an accurate description of the boundaries for the affected areas as previously submitted to EPA by the States and/or included in the January 5 technical support document. In the January 5, 2005, action, these errors were inadvertently made in the process of drafting the text for the part 81 tables. The corrections made by EPA in today's rule are listed in the tables at the end of this notice, and these changes will be reflected in a revision of 40 CFR part 81.

IV. Significance of Today's Action

Based on the foregoing discussion, EPA is today making changes to the January 5, 2005 (70 FR 944), rulemaking which designated areas for the PM2.5 NAAQS. The corrections made by EPA in today's rule, related to the designations for the PM2.5 standard, are set forth in the tables at the end of this notice, and will change the designation description for the affected areas in 40 CFR part 81 initially announced in the January 5, 2005, action. States with areas designated as nonattainment for the PM2.5 NAAQS are required to submit State Implementation Plans (SIPs) addressing nonattainment area requirements within 3 years of designation, pursuant to section 172 of the CAA. Therefore, within 3 years following the April 5, 2005, effective date for the designations identified in the January 5, 2005 (70 FR 944), rulemaking, States will be required to submit SIPs for nonattainment areas. The EPA intends to issue another rule that will assist States in developing SIPs that meet the requirements of the CAA. The EPA plans to issue the proposal for that rulemaking in the near future.

V. Effective Date of Today's Action

The effective date of designations of areas corrected or changed in today's rule is April 5, 2005, the date indicated in the January 5, 2005 (70 FR 944), PM2.5 designation rulemaking. The EPA is making these changes without notice and comment in accordance with section 107(d)(2) of the CAA, which exempts the promulgation of these designations from the notice and comment provisions of the Administrative Procedures Act. Section 553(d) of the Administrative Procedures Act generally provides that rulemakings shall not be effective less than 30 days after publication except where a substantive rule relieves a restriction or where the agency finds good cause for an earlier date. 5 U.S.C. 553(d)(1) and (3). Were EPA not to expedite the effective date of today's action, a number of areas would continue to be designated nonattainment or unclassifiable, in spite of 2004 data that indicate a change of designation is appropriate. Because EPA has concluded that a change of designation is already appropriate based on available information, EPA believes that it would serve no purpose to require the States in question to pursue redesignation through other means that may result in delay and the unnecessary expenditure of resources. The effective date for today's action is therefore justified because: (1) It relieves a restriction by eliminating a restriction by eliminating inappropriate nonattainment or unclassifiable designations that would otherwise become effective on April 5, 2005, and (2) it is in the public interest to avoid the potential delay and waste of resources associated with allowing the January 5, 2005 designations to go into effect for these areas.

VI. Statutory and Executive Order Reviews

Upon promulgation of a new or revised NAAQS, the CAA requires EPA to designate areas with respect to their attainment of such NAAQS. The CAA imposes requirements for areas based upon whether such areas are attaining or not attaining the NAAQS. In this final rule, EPA assigns designations to areas as required.

A. Executive Order 12866: Regulatory Planning and Review.

Under Executive Order 12866 (58 FR 51735, October 4, 1993), EPA must determine whether the regulatory action is ''significant'' and, therefore, subject to the Office of Management and Budget (OMB) review and the requirements of the Executive Order. The order defines ''significant regulatory action'' as one that is likely to result in a rule that may: (1) Have an annual effect on the economy of $100 million or more or adversely affect in a material way the economy, a sector of the economy, productivity, competition, jobs, the environment, public health or safety, or State, local, or Tribal governments or communities; (2) create a serious inconsistency or otherwise interfere with an action taken or planned by another agency; (3) materially alter the budgetary impact of entitlements, grants, user fees, or loan programs or the rights and obligations of recipients thereof; or (4) raise novel legal or policy issues arising out of legal mandates, the President's priorities, or the principles set forth in the Executive Order.

Pursuant to the terms of Executive Order 12866, it has been determined that this rule is not a ''significant regulatory action'' because none of the above factors apply. As such, this final rule was not formally submitted to OMB for review.

B. Paperwork Reduction Act

This action does not impose an information collection burden under the provisions of the Paperwork Reduction Act, 44 U.S.C. 3501 *et seq.* This rule responds to the requirement to promulgate air quality designations after promulgation of a NAAQS. This requirement is prescribed in the CAA section 107 of title 1. The present final rule does not establish any new information collection apart from that required by law. Burden means that total time, effort, or financial resources expended by persons to generate, maintain, retain, or disclose or provide information to or for a Federal agency. This includes the time needed to review instructions; develop, acquire, install, and utilize technology and systems for the purposes of collecting, validating, and verifying information, processing and maintaining information, and disclosing and providing information; adjust the existing ways to comply with any previously applicable instructions and requirements; train personnel to be able to respond to a collection of information; search data sources; complete and review the collection of information; and transmit or otherwise disclose the information. An Agency may not conduct or sponsor, and a person is not required to respond to a collection of information unless it displays a currently valid OMB control number. The OMB control numbers for EPA's regulations in the CFR are listed in 40 CFR part 9.

C. Regulatory Flexibility Act

Today's rule is not subject to the Regulatory Flexibility Act (RFA), which generally requires an agency to prepare a regulatory flexibility analysis for any rule that will have a significant economic impact on a substantial number of small entities. The RFA applies only to rules subject to notice and comment rulemaking requirements under the Administrative Procedure Act (APA) or any other statute. This rule is not subject to notice and comment requirements under the APA or any other statute because it was not subject to notice and comment rulemaking requirements. *See* CAA section 107(d)(2)(B).

D. Unfunded Mandates Reform Act

Title II of the Unfunded Mandates Reform Act of 1995 (UMRA), Public Law 104–4, establishes requirements for Federal Agencies to assess the effects of their regulatory actions on State, local and Tribal governments and the private sector. Under section 202 of the UMRA, EPA generally must prepare a written statement, including a cost-benefit analysis, for proposed and final rules with ''Federal mandates'' that may result in expenditures to State, local, and Tribal governments, in the aggregate, or to the private sector, of $100 million or more in any 1 year. Before promulgating an EPA rule for which a written statement is needed, section 205 of the UMRA generally requires EPA to identify and consider a reasonable number of regulatory alternatives and adopt the least costly, most cost-effective or least burdensome alternative that achieves the objectives of the rule. The provisions of section 205 do not apply when they are inconsistent with applicable law. Moreover, section 205 allows EPA to adopt an alternative other than the least costly, most cost-effective or least burdensome alternative if the Administrator publishes with the final rule an explanation of why that alternative was not adopted. Before EPA establishes any regulatory requirements that may significantly or uniquely affect small governments, including Tribal governments, it must have developed under section 203 of the UMRA a small government agency plan. The plan must provide for notifying potentially affected small governments to have meaningful and timely input in the development of EPA regulatory proposals with significant Federal intergovernmental mandates, and informing, educating, and advising small government on compliance with regulatory requirements.

Today's final action does not include a Federal mandate within the meaning of UMRA that may result in expenditures of $100 million or more in any 1 year by either State, local, or Tribal governments in the aggregate or to the private sector, and therefore, is not subject to the requirements of sections 202 and 205 of the UMRA. It does not create any additional requirements beyond those of the PM2.5 NAAQS (62 FR 38652; July 18, 1997), therefore, no UMRA analysis is needed. This rule establishes the application of the PM2.5 standard and the designation for each area of the country for the PM2.5 NAAQS. The CAA requires States to develop plans, including control measures, based on their designations and classifications.

One mandate that may apply as a consequence of this action to all designated nonattainment areas is the requirement under CAA section 176(c) and associated regulations to demonstrate conformity of Federal actions to SIPs. These rules apply to Federal agencies and Metropolitan Planning Organizations (MPOs) making conformity determinations. The EPA concludes that such conformity determinations will not cost $100 million or more in the aggregate.

The EPA believes that any new controls imposed as a result of this action will not cost in the aggregate $100 million or more annually. Thus, this Federal action will not impose mandates that will require expenditures of $100 million or more in the aggregate in any 1 year.

Nonetheless, EPA carried out consultation with government entities affected by this rule, including States, Tribal governments, and local air pollution control agencies.

E. Executive Order 13132: Federalism

Executive Order 13132, entitled ''Federalism'' (64 FR 43255, August 10, 1999), requires EPA to develop an accountable process to ensure ''meaningful and timely input by State and local officials in the development of regulatory policies that have federalism implications.'' ''Policies that have federalism implications'' is defined in the Executive Order to include regulations that have ''substantial direct effects on the States, or the relationship between the national government and the States, or on the distribution of power and responsibilities among the various levels of government.''

This final rule does not have federalism implications. It will not have substantial direct effects on the States, on the relationship between the national government and the States, or on the distribution of power and responsibilities among the various levels of government, as specified in Executive Order 13132. The CAA establishes the scheme whereby States take the lead in developing plans to meet the NAAQS. This rule will not modify the relationship of the States and EPA for purposes of developing programs to implement the NAAQS. Thus, Executive Order 13132 does not apply to this rule.

F. Executive Order 13175: Consultation and Coordination With Indian Tribal Governments

Executive Order 13175, entitled ''Consultation and Coordination with Indian Tribal Governments'' (65 FR 67249, November 9, 2000), requires EPA to develop an accountable process to ensure ''meaningful and timely input by Tribal officials in the development of regulatory policies that have Tribal implications.'' This final rule does not have ''Tribal implications'' as specified in Executive Order 13175. This rule concerns the designation and classification of areas as attainment and nonattainment for the PM2.5 air quality standard. The CAA provides for States to develop plans to regulate emissions of air pollutants within their jurisdictions. The Tribal Authority Rule (TAR) provides Tribes the opportunity to develop and implement CAA programs such as programs to attain and maintain the PM2.5 NAAQS, but it leaves to the discretion of the Tribe the decision of whether to develop these programs and which programs, or appropriate elements of a program, the Tribe will adopt.

This final rule does not have Tribal implications as defined by Executive Order 13175. It does not have a substantial direct effect on one or more Indian Tribes, since no Tribe has implemented a CAA program to attain the PM2.5 NAAQS at this time. Furthermore, this rule does not affect the relationship or distribution of power and responsibilities between the Federal government and Indian Tribes. The CAA and the TAR establish the relationship of the Federal government and Tribes in developing plans to attain the NAAQS, and this rule does nothing to modify that relationship. Because this rule does not have Tribal implications, Executive Order 13175 does not apply.

Although Executive Order 13175 does not apply to this rule, EPA did outreach to Tribal leaders and environmental staff regarding the designations process. The EPA supports a national ''Tribal Designations and Implementation Work Group'' which provides an open forum for all Tribes to voice concerns to EPA about the designations and implementation process for the NAAQS, including the PM2.5 NAAQS. These discussions informed EPA about key Tribal concerns regarding designations as the rule was under development and gave Tribes the opportunity to express concerns about designations to EPA. Furthermore, EPA sent individualized letters to all federally recognized Tribes about EPA's intention to designate areas for the PM2.5 standard and gave Tribal leaders the opportunity for consultation.

G. Executive Order 13045: Protection of Children From Environmental Health and Safety Risks

Executive Order 13045: ''Protection of Children From Environmental Health and Safety Risks'' (62 FR 19885, April 23, 1997) applies to any rule that (1) is determined to be ''economically significant'' as defined under Executive Order 12866, and (2) concerns an environmental health and safety risk that EPA has reason to believe may have a disproportionate effect on children. If the regulatory action meets both criteria, EPA must evaluate the environmental health or safety effects of the planned rule on children, and explain why the planned regulation is preferable to other potentially effective and reasonably feasible alternatives considered by the EPA.

This final rule is not subject to Executive Order 13045 because it is not economically significant as defined in Executive Order 12866, and because EPA does not have reason to believe that the environmental health risks or safety risks addressed by this rule present a disproportionate risk or safety risk to children. Nonetheless, we have evaluated the environmental health or safety effects of the PM2.5 NAAQS on children. The results of this risk assessment are contained in the NAAQS for PM2.5, Final Rule (July 18, 1997, 62 FR 38652).

H. Executive Order 13211: Actions That Significantly Affect Energy Supply, Distribution, or Use

This rule is not subject to Executive Order 13211, ''Actions That Significantly Affect Energy Supply, Distribution, or Use,'' (66 FR 28355, May 22, 2001) because it is not a significant regulatory action under Executive Order 12866.

Information on the methodology and data regarding the assessment of potential energy impacts is found in Chapter 6 of U.S. EPA 2002, Cost, Emission Reduction, Energy, and the Implementation Framework for the PM2.5 NAAQS, prepared by the Innovative Strategies and Economics Group, Office of Air Quality Planning and Standards, Research Triangle Park, NC, April 24, 2003.

I. National Technology Transfer Advancement Act (NTTAA)

Section 12(d) of the NTTAA of 1995, Public Law 104–113, section 12(d) (15 U.S.C. 272 note) directs EPA to use voluntary consensus standards (VCS) in its regulatory activities unless to do so would be inconsistent with applicable law or otherwise impracticable. Voluntary consensus standards are technical standards (*e.g.*, materials specifications, test methods, sampling procedures, and business practices) that are developed or adopted by VCS bodies. The NTTAA directs EPA to provide Congress, through OMB, explanations when the EPA decides not to use available and applicable VCS.

This action does not involve technical standards. Therefore, EPA did not consider the use of any VCS.

J. Congressional Review Act

The Congressional Review Act, 5 U.S.C. 801 *et seq.*, as added by the Small Business Regulatory Enforcement Fairness Act of 1996, generally provides that before a rule may take effect, the agency promulgating the rule must submit a rule report, which includes a copy of the rule, to each House of the Congress and to the Comptroller General of the United States. A major rule cannot take effect until 60 days after it is published in the **Federal Register**. This action is not a ''major rule'' as defined by 5 U.S.C. 804(2). Pursuant to 5 U.S.C. 801, whether major or not, a rule generally cannot take effect until after submission of a rule report, including a copy of the rule, to each House of Congress and to the Comptroller General of the United States. A statutory exception to that requirement is provided in 5 U.S.C. 808(2), which provides that for a rule for which an agency for good cause finds ''that notice and public procedure thereon are impractical, unnecessary, or contrary to the public interest, [the rule] shall take effect at such time as the Federal agency promulgating the rule determines.'' The EPA finds that the criteria for the exception contained in 5 U.S.C. 808(2) are satisfied for the following reasons. Section 107(d)(2)(B) of the CAA explicitly exempts the designation process from compliance with the notice and comment procedures of the Administrative Procedures Act and EPA has concluded that it is appropriate to promulgate the designations following the specific procedures provided within section 107(d) of the CAA. Thus, EPA believes that additional notice and public procedure are unnecessary. Given the short time period between the submission by States of 2004 data and today's action, any such additional notice and public process would have been impracticable. Moreover, EPA has concluded that it is in the public interest to modify the designations of certain areas based upon inclusion of 2004 data in order to avoid the potential for delay and the waste of resources for such areas to pursue redesignation through other means. Therefore, EPA finds that notice and public comment procedures are unnecessary, impracticable, and contrary to the public interest for this rule. Thus, in accordance with 5 U.S.C. 808(2), EPA has concluded that today's rule can be effective on April 5, 2005. The EPA will submit a report containing this rule and other required information to the U.S. Senate, the U.S. House of Representatives, and the Comptroller General of the United States prior to publication of the rule in the **Federal Register**.

K. Judicial Review

Section 307(b)(1) of the CAA indicates which Federal Courts of Appeal have venue for petitions of review of final actions by EPA. This section provides, in part, that petitions for review must be filed in the Court of Appeals for the District of Columbia Circuit: (i) When EPA action consists of ''nationally applicable regulations promulgated, or final actions taken, by the Administrator,'' or (ii) when such action is locally or regionally applicable, if ''such action is based on a determination of nationwide scope or effect and if in taking such action the Administrator finds and publishes that such action is based on such a determination.''

This rule designating areas for the PM2.5 NAAQS is ''nationally applicable'' within the meaning of section 307(b)(1). This rule establishes designations for all areas of the United States for the PM2.5 NAAQS. At the core of this rulemaking is EPA's interpretation of the definition of nonattainment under section 107(d)(1) of the CAA. In determining which areas should be designated nonattainment (or conversely, should be designated attainment/unclassifiable), EPA used a set of nine technical factors that it applied consistently across the United States.

For the same reasons, the Administrator also is determining that the final designations are of nationwide scope and effect for the purposes of section 307(b)(1). This is particularly appropriate because in the report on the 1977 Amendments that revised section 307(b)(1) of the CAA, Congress noted that the Administrator's determination that an action is of ''nationwide scope or effect'' would be appropriate for any action that has ''scope or effect beyond a single judicial circuit.'' H.R. Rep. No. 95–294 at 323, 324, *reprinted* in 1977 U.S.C.C.A.N. 1402–03. Here, the scope and effect of this rulemaking extends to numerous judicial circuits since the designations apply to all areas of the

country. In these circumstances, section 307(b)(1) and its legislative history calls for the Administrator to find the rule to be of ''nationwide scope or effect'' and for venue to be in the D.C. Circuit.

Thus, any petitions for review of final designations must be filed in the Court of Appeals for the District of Columbia Circuit within 60 days from the date final action is published in the **Federal Register**.

List of Subjects in 40 CFR Part 81

Environmental protection, Air pollution control, National parks, Wilderness areas.

Dated: April 5, 2005.

Stephen L. Johnson,

Acting Administrator.

■ For the reasons set forth in the preamble, 40 CFR part 81, subpart C is amended as follows:

PART 81—DESIGNATIONS OF AREAS FOR AIR QUALITY PLANNING PURPOSES

■ 1. The authority citation for part 81 continues to read as follows:

Authority: 42 U.S.C. 7401, *et seq.*

Subpart C—Section 107 Attainment Status Designations

■ 2. In § 81.301, the ''Alabama—PM2.5'' table is amended by revising the entries for ''Columbus, GA-AL'',''DeKalb County, AL'' and ''Gadsen, AL'' to read as follows:

§ 81.301 Alabama.

* * * * *

ALABAMA—PM2.5

Designated area	Designation [a]	
	Date [1]	Type
* * * * *	*	*
Columbus GA-AL:		
Russell County, AL	.....	Unclassifiable/Attainment.
* * * * *	*	*
DeKalb County, AL:		
DeKalb County	.....	Unclassifiable/Attainment.
* * * * *	*	*
Gadsden, AL:		
Etowah County	.....	Unclassifiable/Attainment.
* * * * *	*	*

[a] Includes Indian Country located in each county or area, except as otherwise specified.
[1] This date is 90 days after January 5, 2005, unless otherwise noted.

■ 3. In § 81.305, the ''California—PM2.5'' table is amended as follows:

■ a. Under ''Lake Tahoe Air Basin:'' by revising the entry for ''Placer County (part)''.

■ b. By revising the entry for ''Western Mojave Desert and Antelope Valley''.

■ c. By removing the entries for ''San Diego, CA:'' and ''San Diego County Tribal Area:''.

■ d. By adding a new entry for ''San Diego, CA'' at the end of table.

§ 81.305 California.

* * * * *

CALIFORNIA—PM2.5

Designated area	Designation [a]	
	Date [1]	Type
* * * * *	*	*
Lake Tahoe Air Basin:		
* * * * *	*	*
Placer County (part):		
That portion of Placer County within the drainage area naturally tributary to Lake Tahoe including said Lake, plus that area in the vicinity of the head of the Truckee River described as follows: commencing at the point common to the aforementioned drainage area crestline and the line common to Townships 15 North and 16 North, Mount Diablo Base and Meridian, and following that line in a westerly direction to the northwest corner of Section 3, Township 15 North, Range 16 East, Mount Diablo Base and Meridian, thence south along the west line of Sections 3 and 10, Township 15 North, Range 16 East, Mount Diablo Base and Meridian, to the intersection with the said drainage area crestline, thence following the said drainage area boundary in a southeasterly, then northeasterly direction to and along the Lake Tahoe Dam, thence following the said drainage area crestline in a northeasterly, then northwesterly direction to the point of beginning.	.....	Unclassifiable/Attainment.
* * * * *	*	*
Western Mojave Desert and Antelope Valley:		

CALIFORNIA—PM2.5—Continued

Designated area	Designation [a]	
	Date [1]	Type
Los Angeles County (part):		
That portion of Los Angeles County which lies north and east of a line described as follows: Beginning at the Los Angeles—San Bernardino County boundary and running west along the Township line common to Township 3 North and Township 2 North, San Bernardino Base and Meridian; then north along the range line common to Range 8 West and Range 9 West; then west along the Township line common to Township 4 North and Township 3 North; then north along the range line common to Range 12 West and Range 13 West to the southeast corner of Section 12, Township 5 North and Range 13 West; then west along the south boundaries of Sections 12, 11, 10, 9, 8, and 7, Township 5 North and Range 13 West to the boundary of the Angeles National Forest which is collinear with the range line common to Range 13 West and Range 14 West; then north and west along the Angeles National Forest boundary to the point of intersection with the Township line common to Township 7 North and Township 6 North (point is at the northwest corner of Section 4 in Township 6 North and Range 14 West); then west along the Township line common to Township 7 North and Township 6 North; then north along the range line common to Range 15 West and Range 16 West to the southeast corner of Section 13, Township 7 North and Range 16 West; then along the south boundaries of Sections 13, 14, 15, 16, 17, and 18, Township 7 North and Range 16 West; then north along the range line common to Range 16 West and Range 17 West to the north boundary of the Angeles National Forest (collinear with the Township line common to Township 8 North and Township 7 North); then west and north along the Angeles National Forest boundary to the point of intersection with the south boundary of the Rancho La Liebre Land Grant; then west and north along this land grant boundary to the Los Angeles-Kern County boundary.	.....	Unclassifiable/Attainment.

RIN 2060–AK74

Clean Air Fine Particle Implementation Rule

AGENCY: Environmental Protection Agency (EPA).

ACTION: Final rule.

SUMMARY: This final action provides rules and guidance on the Clean Air Act (CAA) requirements for State and Tribal plans to implement the 1997 fine particle ($PM_{2.5}$) national ambient air quality standards (NAAQS). Fine particles and precursor pollutants are emitted by a wide range of sources, including power plants, cars, trucks, industrial sources, and other burning or combustion-related activities. Health effects that have been associated with exposure to $PM_{2.5}$ include premature death, aggravation of heart and lung disease, and asthma attacks. Those particularly sensitive to $PM_{2.5}$ exposure include older adults, people with heart and lung disease, and children.

Air quality designations became effective on April 5, 2005 for 39 areas (with a total population of 90 million) that were not attaining the 1997 $PM_{2.5}$ standards. By April 5, 2008, each State having a nonattainment area must submit to EPA an attainment demonstration and adopted regulations ensuring that the area will attain the standards as expeditiously as practicable, but no later than 2015. This rule and preamble describe the requirements that States and Tribes must meet in their implementation plans for attainment of the 1997 fine particle NAAQS. (Note that this rule does not include final $PM_{2.5}$ requirements for the new source review (NSR) program; the final NSR rule will be issued at a later date.)

DATES: This rule is effective on May 29, 2007.

ADDRESSES: The EPA has established a docket for this action under Docket ID EPA–HQ–OAR–2003–0062. All documents relevant to this action are listed in the Federal docket management system at *www.regulations.gov*. Although listed in the index, some information is not publicly available (e.g. Confidential Business Information or other information whose disclosure is restricted by statute). Certain other material, such as copyrighted material, is not placed on the Internet and will be publicly available only in hard copy form. Publicly available docket materials are available either electronically through www.regulations.gov or in hard copy format at the EPA Docket Center, EPA/DC, EPA West, Room 3334, 1301 Constitution Avenue, NW., Washington, DC. The Public Reading Room is open from 8:30 a.m. to 4:30 p.m., Monday through Friday, excluding legal holidays. The telephone number for the Public Reading Room is (202) 566–1744, and the telephone number for the Office of Air and Radiation Docket and Information Center is (202) 566–1742. A variety of information and materials related to the fine particle NAAQS and implementation program are also available on EPA's Web site: *http://www.epa.gov/air/particles*.

FOR FURTHER INFORMATION CONTACT: For general information, contact Mr. Richard Damberg, U.S. Environmental Protection Agency, Office of Air Quality Planning and Standards, Mail Code C539–01, Research Triangle Park, NC 27711, phone number (919) 54l–5592 or by e-mail at: *damberg.rich@epa.gov*.

SUPPLEMENTARY INFORMATION:

General Information

A. Does this action apply to me?

Entities potentially regulated by this action are State and local air quality agencies.

B. Where can I get a copy of this document and other related information?

In addition to being available in the docket, an electronic copy of this final rule will also be available on the World Wide Web. Following signature by the EPA Administrator, a copy of this final rule will be posted at *http://www.epa.gov/particles/actions.html*.

C. How is the preamble organized?

I. Background

Fine particles in the atmosphere are comprised of a complex mixture of components. Common constituents include: sulfate (SO_4); nitrate (NO_3); ammonium; elemental carbon; a great variety of organic compounds; and inorganic material (including metals, dust, sea salt, and other trace elements) generally referred to as ''crustal'' material, although it may contain material from other sources. Airborne particles generally less than or equal to 2.5 micrometers in diameter are considered to be ''fine particles'' (also referred to as $PM_{2.5}$). (A micrometer is one-millionth of a meter, and 2.5 micrometers is less than one-seventh the average width of a human hair.) ''Primary'' particles are emitted directly into the air as a solid or liquid particle (e.g., elemental carbon from diesel engines or fire activities, or condensable organic particles from gasoline engines). ''Secondary'' particles (e.g., sulfate and nitrate) form in the atmosphere as a result of various chemical reactions. (Section II of the proposed rule included detailed technical discussion on $PM_{2.5}$, its precursors, formation processes, and emissions sources.)

The EPA established air quality standards for $PM_{2.5}$ based on evidence from numerous health studies demonstrating that serious health effects are associated with exposures to elevated levels of $PM_{2.5}$. Epidemiological studies have shown statistically significant correlations between elevated $PM_{2.5}$ levels and premature mortality. Other important

effects associated with $PM_{2.5}$ exposure include aggravation of respiratory and cardiovascular disease (as indicated by increased hospital admissions, emergency room visits, absences from school or work, and restricted activity days), changes in lung function and increased respiratory symptoms, as well as new evidence for more subtle indicators of cardiovascular health. Individuals particularly sensitive to $PM_{2.5}$ exposure include older adults, people with heart and lung disease, and children.

On July 18, 1997, we revised the NAAQS for particulate matter (PM) to add new standards for fine particles, using $PM_{2.5}$ as the indicator. We established health-based (primary) annual and 24-hour standards for $PM_{2.5}$ (62 FR 38652).[1] The annual standard was set at a level of 15 micrograms per cubic meter, as determined by the 3-year average of annual mean $PM_{2.5}$ concentrations. The 24-hour standard was set at a level of 65 micrograms per cubic meter, as determined by the 3-year average of the 98th percentile of 24-hour concentrations.

Attainment of the 1997 $PM_{2.5}$ standards is estimated to lead to reductions in health impacts, including tens of thousands fewer premature deaths each year, thousands fewer hospital admissions and emergency room visits each year, hundreds of thousands fewer absences from work and school, and hundreds of thousands fewer respiratory illnesses in children annually. The EPA's evaluation of the science concluded that there was not sufficient information to either support or refute the existence of a threshold for health effects from PM exposure.[2]

We subsequently completed in October 2006 another review of the NAAQS for PM. With regard to the primary standards, the 24-hour $PM_{2.5}$ standard was strengthened to a level of 35 micrograms per cubic meter, based on the 3-year average of the 98th percentile of 24-hour concentrations, and the level of the annual standard remained unchanged.[3] Attainment of the 2006 $PM_{2.5}$ standards is estimated to lead to additional reductions in health impacts, including approximately 1,200 to 13,000 fewer premature deaths each year, 1,630 fewer hospital admissions and 1,200 fewer emergency room visits for asthma each year, 350,000 fewer absences from work and school, and 155,300 fewer respiratory illnesses in children annually.[4]

In both 1997 and 2006 EPA established welfare-based (secondary) standards identical to the levels of the primary standards. The secondary standards are designed to protect against major environmental effects of $PM_{2.5}$ such as visibility impairment, soiling, and materials damage. The EPA also established the regional haze regulations in 1999 for the improvement of visual air quality in national parks and wilderness areas across the country. Because regional haze is caused primarily by light scattering and light absorption by fine particles in the atmosphere, EPA is encouraging the States to integrate their efforts to attain the $PM_{2.5}$ standards with those efforts to establish reasonable progress goals and associated emission reduction strategies for the purposes of improving air quality in our treasured natural areas under the regional haze program.

The scientific assessments used in the development of the $PM_{2.5}$ standards included a scientific peer review and public comment process. We developed scientific background documents based on the review of hundreds of peer-reviewed scientific studies. The Clean Air Scientific Advisory Committee, a congressionally mandated group of independent scientific and technical experts, provided extensive review of these assessments, and found that EPA's review of the science provided an adequate basis for the EPA Administrator to make a decision. More detailed information on health effects of $PM_{2.5}$ can be found on EPA's Web site at: *http://www.epa.gov/air/urbanair/pm/index.html*. Additional information on EPA's scientific assessment documents supporting the 1997 standards are available at *http://www.epa.gov/ttn/oarpg/t1cd.html*; additional scientific assessment information on the 2006 standards is available at: *http://www.epa.gov/ttn/naaqs/standards/pm/s_pm_cr_cd.html.*

The EPA issued final $PM_{2.5}$ designations for areas violating the 1997 standards on December 17, 2004. They were published in the **Federal Register** on January 5, 2005 (70 FR 944). On April 5, 2005, EPA issued a supplemental notice which changed the designation status of eight areas from nonattainment to attainment based on newly updated 2002–2004 air quality data (70 FR 19844; published in the **Federal Register** on April 14, 2005). A total of 39 areas were designated as nonattainment for the 1997 $PM_{2.5}$ standards. The population of these areas is estimated at about 90 million (or more than 30% of the U.S. population). Most of these areas only violate the annual standard, but a few violate both the annual and 24-hour standards.

The nonattainment designation for an area starts the process whereby a State or Tribe must develop an implementation plan that includes, among other things, a demonstration showing how it will attain the ambient standards by the attainment dates required in the CAA. Under section 172(b), States have up to 3 years after EPA's final designations to submit their SIPs to EPA. These SIPs will be due on April 5, 2008, 3 years from the effective date of the designations.

Section 172(a)(2) of the Act requires States to attain the standards as expeditiously as practicable but within 5 years of designation (i.e. attainment date of April 2010 based on air quality data for 2007–2009), or within up to 10 years of designation (i.e. to April 2015) if the EPA Administrator extends an area's attainment date by 1–5 years based upon the severity of the nonattainment problem or the feasibility of implementing control measures.

Virtually all nonattainment problems appear to result from a combination of local emissions and transported emissions from upwind areas. The structure of the CAA requires EPA to develop national rules for certain types of sources which are also significant contributors to local air quality problems, including motor vehicles and fuels. It also provides for States to address emissions sources on an area-specific basis through such requirements as RACT, RACM, and RFP.

We believe that to attain the $PM_{2.5}$ standards, it is important to pursue emissions reductions simultaneously on the local, regional, and national levels. The EPA issued the Clean Air Interstate

[1] The original annual and daily standards for particles generally less than or equal to 10 micrometers in diameter (also referred to as PM_{10}) were established in 1987. In the 1997 PM NAAQS revision, EPA also revised the standards for PM_{10}, but these revised PM_{10} standards were later vacated by the court, and the 1987 PM_{10} standards remained in effect. In the 2006 NAAQS revision, the 24-hour PM_{10} standard was retained but the annual standard was revoked. Today's implementation rule and guidance does not address PM_{10}.

Research Triangle Park, NC: National Center for Environmental Assessment—RTP, Office of Research and Development, U.S. Environmental Protection Agency, Research Triangle Park, NC 27711; report no. EPA/600/P–99/002aF and EPA/600/P–99/002bF. October 2004.

[3] The revised fine particle NAAQS were published on October 17, 2006 (71 FR 61144). See EPA's Web site for additional information: *http://www.epa.gov/pm/index.html.*

[4] Regulatory Impact Analysis for Particulate Matter National Ambient Air Quality Standards (September 2006), page ES–8. The mortality range includes estimates based on the results of an expert elicitation study, along with published epidemiological studies.

Rule (CAIR)[5] on March 10, 2005 to address the interstate transport of sulfur dioxide and nitrogen oxide emissions primarily from power plants. Section 110 gives EPA the authority to require SIPs to ''prohibit * * * any source or other type of emission activity within the State from emitting any air pollutant in amounts which will contribute significantly to nonattainment in, or interfere with maintenance by, any other State with respect to'' any NAAQS, and to prohibit sources or emission activities from emitting pollutants in amounts which will interfere with measures required to be included in State plans to prevent significant deterioration of air quality or to protect visibility (such as the protection of 156 mandatory Federal class I areas under the regional haze rule[6]). CAIR employs the same emissions trading approach used to achieve cost-effective emission reductions under the acid rain program. It outlines a two-phase program with increasingly tighter power plant emissions caps for 28 eastern states and the District of Columbia: SO_2 caps of 3.6 million tons in 2010, and 2.5 million in 2015; NO_X caps of 1.5 in 2009 and 1.3 in 2015; and NO_X ozone season caps of 580,000 tons in 2009 and 480,000 tons in 2015. Emission caps are divided into State SO_2 and NO_X budgets. By the year 2015, the Clean Air Interstate Rule is estimated to result in:

—$85 to $100 billion in annual health benefits, including preventing 17,000 premature deaths, millions of lost work and school days, and tens of thousands of non-fatal heart attacks and hospital admissions annually.
—Nearly $2 billion in annual visibility benefits in southeastern national parks, such as Great Smoky and Shenandoah.
—Significant regional reductions in sulfur and nitrogen deposition, reducing the number of acidic lakes and streams in the eastern U.S.

Over the past several years, EPA has also issued a number of regulations addressing emissions standards for new cars, trucks and buses. These standards are providing reductions in motor vehicle emissions of volatile organic compounds (VOCs, also referred to as hydrocarbons), NO_X, and direct PM emissions (such as elemental carbon) as older vehicles are retired and replaced. Other existing rules are designed to reduce emissions from several categories of nonroad engines. The Tier 2 motor vehicle emission standards, together with the associated requirements to reduce sulfur in gasoline, are estimated to provide additional benefits nationally beginning in 2004.[7] When the new tailpipe and sulfur standards are fully implemented, Americans are estimated to benefit from the clean-air equivalent of removing 164 million cars from the road. These new standards require passenger vehicles to have emissions 77 to 95 percent cleaner than those on the road today and require fuel manufacturers to reduce the sulfur content of gasoline by up to 90 percent. In addition, the 2001 heavy-duty diesel engine regulations[8] will lead to continued emissions reductions as older vehicles in that engine class are retired and fleets turn over. New emission standards began to take effect for model year 2007 and apply to heavy-duty highway engines and vehicles. These standards are based on the use of high-efficiency catalytic exhaust emission control devices or comparably effective advanced technologies. Because these devices are damaged by sulfur, the level of sulfur in highway diesel fuel was to be reduced by 97 percent by mid-2006. We project a 2.6 million ton reduction of NO_X emissions in 2030 when the current heavy-duty vehicle fleet is completely replaced with newer heavy-duty vehicles that comply with these emission standards. By 2030, we estimate that this program will reduce annual emissions of hydrocarbons by 115,000 tons and PM by 109,000 tons. These emissions reductions are on par with those that we anticipate from new passenger vehicles and low sulfur gasoline under the Tier 2 program.

The EPA also finalized national rules in May 2004 to reduce significantly $PM_{2.5}$ and NO_X emissions from nonroad diesel-powered equipment.[9] These nonroad sources include construction, agricultural, and industrial equipment, and their emissions constitute an important fraction of the inventory for direct $PM_{2.5}$ emissions (such as elemental carbon and organic carbon), and NO_X. The EPA estimates that affected nonroad diesel engines currently account for about 44 percent of total diesel PM emissions and about 12 percent of total NO_X emissions from mobile sources nationwide. These proportions are even higher in some urban areas. The diesel emission standards will reduce emissions from this category by more than 90 percent, and are similar to the onroad engine requirements implemented for highway trucks and buses. Because the emission control devices can be damaged by sulfur, EPA also established requirements to reduce the allowable level of sulfur in nonroad diesel fuel by more than 99 percent by 2010. In 2030, when the full inventory of older nonroad engines has been replaced, the nonroad diesel program will annually prevent up to 12,000 premature deaths, one million lost work days, 15,000 heart attacks and 6,000 children's asthma-related emergency room visits.

The EPA expects the implementation of regional and national emission reduction programs such as CAIR and the suite of mobile source rules described above to provide significant air quality improvements for $PM_{2.5}$ nonattainment areas. At the same time, analyses for the final CAIR rule indicate that without implementation of local measures, a number of $PM_{2.5}$ areas are projected to remain in nonattainment status in the 2010–2015 timeframe. Thus, EPA believes that local and State emission reduction efforts will need to play an important role in addressing the $PM_{2.5}$ problem as well. The EPA will work closely with States, Tribes, and local governments to develop appropriate in-state pollution reduction measures to complement regional and national strategies to meet the standards expeditiously and in a cost-effective manner. States will need to evaluate technically and economically feasible emission reduction opportunities and determine which measures can be reasonably implemented in the near term. Local and regional emission reduction efforts should proceed concurrently and expeditiously.

The promulgation of a revised 24-hour $PM_{2.5}$ standard effective on December 18, 2006 has initiated another process of State recommendations, and the eventual designation by EPA of areas not attaining the revised standard. The additional designations are to be completed within two years from the effective date, although EPA may take an additional year to complete the designations if it determines it does not have sufficient information. State plans to attain the 24-hour standard would then be due within three years of the final designations. A number of areas, including some that are already designated as not attaining the 1997 standards, may be exceeding the revised 24-hour standard. The EPA encourages State and local governments to be mindful of the strengthened 24-hour standard as they adopt emission reduction strategies to attain the 1997 standards. Such steps may help with

future attainment efforts, or even help some areas avoid a nonattainment designation for the 24-hour standard in the first place.

The public health benefits of meeting the $PM_{2.5}$ standards are estimated to be significant. Even small reductions in $PM_{2.5}$ levels may have substantial health benefits on a population level. For example, in a moderate-sized metropolitan area with a design value of 15.5 µg/m3, efforts to improve annual average air quality down to the level of the standard (15.0 µg/m3) are estimated to result in as many as 25–50 fewer mortalities per year due to air pollution exposure. In a smaller city, the same air quality improvement from 15.5 to 15.0 µg/m3 still are estimated to result in a number of avoided mortalities per year. These estimates are based on EPA's standard methodology for calculating health benefits as used in recent rulemakings.[10] In addition, because many different precursors contribute to the formation of fine particles, reductions in pollutants that contribute to $PM_{2.5}$ also can provide concurrent benefits in addressing a number of other air quality problems—such as ground-level ozone, regional haze, toxic air pollutants, and urban visibility impairment.

In order to assist States in developing effective plans to address the local component of the $PM_{2.5}$ nonattainment problem, EPA is issuing this final fine particle implementation rule. The EPA is issuing this rule to implement the 1997 $PM_{2.5}$ NAAQS in accordance with the statutory requirements of the CAA set forth in Subpart 1 of Part D of Title 1, *i.e.*, sections 171–179B of the Act. The EPA believes that the CAA directs the Agency to implement new or revised NAAQS in nonattainment areas solely in accordance with Subpart 1, unless another Subpart of the Act also applies to the particular NAAQS at issue. In this case, EPA has concluded that Congress did not intend the Agency to implement particulate matter NAAQS other than those using PM_{10} as the indicator in accordance with Subpart 4 of Part D of Title 1, *i.e.*, sections 188–190 of the CAA. Moreover, EPA believes that implementation of the $PM_{2.5}$ NAAQS under the provisions of Subpart 1 is more appropriate, given the inherent nature of the $PM_{2.5}$ nonattainment problem. In contrast to PM_{10}, EPA anticipates that achieving the NAAQS for $PM_{2.5}$ will generally require States to evaluate different sources for controls, to consider controls of one or more precursors in addition to direct PM emissions, and to adopt different control strategies. As a result, EPA has concluded that the provisions of Subpart 1 will allow States and EPA to tailor attainment plans so that they can be based more specifically upon the facts and circumstances of each nonattainment area.

The proposed clean air fine particle implementation rule was issued on November 1, 2005 (70 FR 65984). About 100 comments were received from private citizens and parties representing industry, state and local governments, environmental groups, and federal agencies. Section II of this document describes the primary elements of the fine particle implementation program. Each section summarizes the relevant policies and options discussed in the proposed rule, discusses the final policy set forth by EPA in the final rule, and provides responses to the major comments received on each issue.

II. Elements of the Clean Air Fine Particle Implementation Rule

A. Precursors and Pollutants Contributing to Fine Particle Formation

1. Introduction

The main precursor gases associated with fine particle formation are SO_2, NO_X, volatile organic compounds (VOC), and ammonia. This section provides technical background on each precursor, discusses the policy approach for addressing each precursor under the $PM_{2.5}$ implementation program, and responds to key issues raised in the public comment process. A subsection is also included on direct $PM_{2.5}$ emissions to address key comments received on this issue as well.

Gas-phase precursors SO_2, NO_X, VOC, and ammonia undergo chemical reactions in the atmosphere to form secondary particulate matter. Formation of secondary PM depends on numerous factors including the concentrations of precursors; the concentrations of other gaseous reactive species; atmospheric conditions including solar radiation, temperature, and relative humidity (RH); and the interactions of precursors with preexisting particles and with cloud or fog droplets. Several atmospheric aerosol species, such as ammonium nitrate and certain organic compounds, are semivolatile and are found in both gas and particle phases. Given the complexity of PM formation processes, new information from the scientific community continues to emerge to improve our understanding of the relationship between sources of PM precursors and secondary particle formation.

As an initial matter, it is helpful to clarify the terminology we use throughout this notice to discuss precursors. We recognize NO_X, SO_2, VOCs, and ammonia as precursors of $PM_{2.5}$ in the scientific sense because these pollutants can contribute to the formation of $PM_{2.5}$ in the ambient air. In section II.K on emission inventory issues, we make the point that because of the complex and variable interaction of multiple pollutants and precursors in the formation of fine particles, it is important for States and EPA to continue to characterize and improve the emissions inventories for all $PM_{2.5}$ precursors. The States and EPA need to use the best available information available in conducting air quality modeling and other assessments. At the same time, the refinement of emissions inventories, the overall contribution of different fine particle precursors to $PM_{2.5}$ formation, and the efficacy of alternative potential control measures will vary by location. This requires that we further consider in this action how States should address these $PM_{2.5}$ precursors in their $PM_{2.5}$ attainment plan programs. Thus, we require emission inventories to include the best available information on all pollutants and precursors that contribute to $PM_{2.5}$ concentrations, and at same time we use the term ''$PM_{2.5}$ attainment plan precursor'' to describe only those precursors that are required to be evaluated for control strategies in a specific $PM_{2.5}$ nonattainment area or maintenance area plan.

In this rule, EPA has not made a finding that all precursors should be evaluated for possible controls in each specific nonattainment area. The policy approach in the rule instead requires sulfur dioxide to be evaluated for control measures in all areas, and describes general presumptive policies for NO_X, ammonia, and VOC for all nonattainment areas. The rule provides a mechanism by which the State and/or EPA can make an area-specific demonstration to reverse the general presumption for these three precursors. States must also consider any relevant information brought forward by interested parties in the SIP planning and development process. (See section II.A.8 for additional discussion on these issues.)

In the following sections, we discuss how States must evaluate $PM_{2.5}$ precursors for nonattainment program issues in $PM_{2.5}$ implementation plans,

[10] See: U.S. EPA 2006. Regulatory Impact Analysis for the Particulate Matter National Ambient Air Quality Standards. Air Benefits and Cost Group, Office of Air Quality Planning and Standards, Research Triangle Park, N.C. October 6, 2006. Appendix A provides an analysis of estimated benefits and costs of attaining the 1997 PM NAAQS standards in 2015.

including issues such as RACT, RACM, and reasonable further progress. This discussion in the final rule is linked to precursor policies for the implementation of the new source review program, the transportation conformity program, the general conformity program, and the regional haze program. All of these programs take effect prior to approval of SIPs for attaining the $PM_{2.5}$ NAAQS. In the case of NSR, the program applies on the effective date of the nonattainment area designation. In the case of transportation conformity and general conformity, the program takes effect 1 year from the effective date of designation of the nonattainment area (i.e., April 5, 2006 for areas designated nonattainment effective April 5, 2005). Thus, for each of these programs there is an interim period between the date the program becomes applicable to a given nonattainment area and the date the State receives EPA approval of its overall $PM_{2.5}$ implementation plan.

2. Legal Authority to Regulate Precursors

a. Background

The CAA authorizes the Agency to regulate criteria pollutant precursors. The term ''air pollutant'' is defined in section 302(g) to include ''any precursors to the formation of any air pollutant, to the extent the Administrator has identified such precursor or precursors for the particular purpose for which the term 'air pollutant' is used.'' The first clause of this second sentence in section 302(g) explicitly authorizes the Administrator to identify and regulate precursors as air pollutants under other parts of the CAA. In addition, the second clause of the sentence indicates that the Administrator has discretion to identify which pollutants should be classified as precursors for particular regulatory purposes. Thus, we do not necessarily construe the CAA to require that EPA identify a particular precursor as an air pollutant for all regulatory purposes where it can be demonstrated that various CAA programs address different aspects of the air pollutant problem. Likewise, we do not interpret the CAA to require that EPA treat all precursors of a particular pollutant the same under any one program when there is a basis to distinguish between such precursors. For example, in a rule addressing $PM_{2.5}$ precursors for purposes of the transportation conformity program, we chose to adopt a different approach for one precursor based on the limited emissions of that precursor from onroad mobile sources and the degree to which it contributes to $PM_{2.5}$ concentrations. (70 FR 24280; May 6, 2005).

Other provisions of the CAA reinforce our reading of section 302(g) that Congress intended precursors to NAAQS pollutants to be subject to the air quality planning and control requirements of the CAA, but also recognized that there may be circumstances where it is not appropriate to subject precursors to certain requirements of the CAA. Section 182 of the CAA provides for the regulation of NO_X and VOCs as precursors to ozone in ozone nonattainment areas, but also provides in section 182(f) that major stationary sources of NO_X (an ozone precursor) are not subject to emission reductions controls for ozone where the State shows through modeling that NO_X reductions do not decrease ozone. Section 189(e) provides for the regulation of PM_{10} precursors in PM_{10} nonattainment areas, but also recognizes that there may be certain circumstances (e.g. if precursor emission sources do not significantly contribute to PM_{10} levels) where it is not appropriate to apply control requirements to PM_{10} precursors. The legislative history of Section 189(e) recognized the complexity behind the science of precursor transformation into PM_{10} ambient concentrations and the need to harmonize the regulation of PM_{10} precursors with other provisions of the CAA:

> The Committee notes that some of these precursors may well be controlled under other provisions of the CAA. The Committee intends that * * * the Administrator will develop models, mechanisms, and other methodology to assess the significance of the PM_{10} precursors in improving air quality and reducing PM_{10}. Additionally, the Administrator should consider the impact on ozone levels of PM_{10} precursor controls. The Committee expects the Administrator to harmonize the PM_{10} reduction objective of this section with other applicable regulations of this CAA regarding PM_{10} precursors, such as NO_X. See H. Rpt. 101–490, Pt. 1, at 268 (May 17, 1990), reprinted in S. Prt. 103–38, Vol. II, at 3292.

In summary, section 302(g) of the CAA clearly calls for the regulation of precursor pollutants, but the CAA also identifies circumstances when it may not be appropriate to regulate precursors and gives the Administrator discretion to determine how to address particular precursors under various programs required by the CAA. Due to the complexities associated with precursor emissions and their variability from location to location, we believe that in certain situations it may not be effective or appropriate to control a certain precursor under a particular regulatory program or for EPA to require similar control of a particular precursor in all areas of the country.

b. Final Rule

The final rule maintains the same legal basis for regulating precursors as was described in the proposal and in the background section above. We also include a clarification of the term ''significant contributor.''

In the proposal, when considering the impacts of the precursors NO_X, VOC and ammonia on ambient concentrations of particulate matter, we referred to the possibility of reversing the presumed approach for regulating or not regulating a precursor if it can be shown that the precursor in question is or is not a ''significant contributor'' to $PM_{2.5}$ concentrations within the specific nonattainment area. ''Significant contribution'' in this context is a different concept than that in Section 110(a)(2)(D). Section 110(a)(2)(D) prohibits States from emitting air pollutants in amounts which significantly contribute to nonattainment or other air quality problems in other states. Consistent with the discussion of sections 189(e) and 302(g) above, we are clarifying that the use in this implementation rule of the term ''significant contribution'' to the nonattainment area's $PM_{2.5}$ concentration means that a significant change in emissions of the precursor from sources in the state would be projected to provide a significant change in $PM_{2.5}$ concentrations in the nonattainment area. For example, if modeling indicates that a reduction in a state's NO_X emissions would reduce ambient $PM_{2.5}$ levels in the nonattainment area, but that a reduction in ammonia emissions would result in virtually no change in ambient $PM_{2.5}$ levels, this would suggest that NO_X is a significant contributor but that ammonia is not. The EPA in this rule is not establishing a quantitative test for determining whether $PM_{2.5}$ levels in a nonattainment area change significantly in response to reductions in precursor emissions in a state. However, in considering this question, it is relevant to consider that relatively small reductions in $PM_{2.5}$ levels are estimated to result in worthwhile public health benefits.

This approach to identifying a precursor for regulation reflects atmospheric chemistry conditions in the area and the magnitude of emissions of the precursor in the area or State. Assessments of which source categories are more cost effective or technically feasible to control should be part of the later RACT and RACM assessment, to

occur after the basic assessment of which precursors are to be regulated is completed.

In the proposed regulatory text, the provisions for reversing presumptions for NO_X, VOC and ammonia included consideration of whether the precursor would significantly contribute to ''other downwind air quality concerns.'' In the final rule we have removed that language to clarify that identification of attainment plan precursors involves evaluation of the impact on $PM_{2.5}$ levels in a nonattainment area of precursor emissions from sources within the state(s) where the nonattainment area is located. Other parts of the Act, notably section 110(a)(2)(D) and section 126, focus on interstate transport of pollutants.

c. Comments and Responses

Comment: The EPA received several comments supporting EPA's interpretation of 302(g) to determine the appropriate regulatory status of each precursor pollutant.

Response: The EPA agrees with the commenters. In establishing section 302(g), Congress intended that precursors to NAAQS pollutants be subject to the air quality planning and control requirements of the CAA. However, the CAA also recognizes that there may be circumstances where it is not appropriate to subject precursors to certain requirements of the CAA.

Comment: The EPA received several comments regarding the applicability of section 189(e), noting that it requires states to presumptively control sources of PM_{10} precursors except where the EPA ''determines that such sources [of precursors] do not significantly contribute to PM_{10} levels which exceed the standard in the area.'' Several commenters stated that EPA does not have the legal authority to regulate $PM_{2.5}$ precursors in a different manner. Several commenters maintained that all $PM_{2.5}$ precursors presumptively should be subject to regulation unless demonstrated by the State as not a significant contributor to $PM_{2.5}$ concentrations in a specific area.

Response: As stated above, EPA believes that section 302(g) allows the Administrator to presumptively not require certain precursors to be addressed in $PM_{2.5}$ implementation plans generally, while allowing the State or EPA to make a finding for a specific area to override the general presumption. In the following pollutant-specific sections of this preamble, EPA finds that at this time there is sufficient uncertainty regarding whether certain precursors significantly contribute to $PM_{2.5}$ concentrations in all nonattainment areas such that the policy set forth in this rule does not presumptively require certain precursors (ammonia, VOC) to be controlled in each area. However, the State or EPA may reverse the presumption and regulate a precursor if it provides a demonstration showing that the precursor is a significant contributor to $PM_{2.5}$ concentrations in the area. In addition, if in the State's SIP planning and adoption process a commenter provides additional information suggesting an alternative policy for regulating a particular precursor, the State will need to respond to this information in its rulemaking action.

3. Policy for Ammonia

[Section II.E.2 of November 1, 2005 proposed rule (70 FR 65999); sec. 51.1002 in draft and final regulatory text.]

a. Background

Ammonia (NH_3) is a gaseous pollutant that is emitted by natural and anthropogenic sources. Emissions inventories for ammonia are considered to be among the most uncertain of any species related to PM. Ammonia serves an important role in neutralizing acids in clouds, precipitation and particles. In particular, ammonia neutralizes sulfuric acid and nitric acid, the two key contributors to acid deposition (acid rain). Deposited ammonia also can contribute to problems of eutrophication in water bodies, and deposition of ammonium particles may effectively result in acidification of soil as ammonia is taken up by plants. The NARSTO Fine Particle Assessment [11] indicates that reducing ammonia emissions where sulfate concentrations are high may reduce $PM_{2.5}$ mass concentrations, but may also increase the acidity of particles and precipitation. An increase in particle acidity is suspected to be linked with human health effects and with an increase in the formation of secondary organic compounds. Based on the above information and further insights gained from the NARSTO Fine Particle Assessment, it is apparent that the formation of particles related to ammonia emissions is a complex, nonlinear process.

Though recent studies have improved our understanding of the role of ammonia in aerosol formation, ongoing research is required to better describe the relationships between ammonia emissions, particulate matter concentrations, and related impacts. The control techniques for ammonia and the analytical tools to quantify the impacts of reducing ammonia emissions on atmospheric aerosol formation are both evolving. Also, area-specific data are needed to evaluate the effectiveness of reducing ammonia emissions on reducing $PM_{2.5}$ concentrations in different areas, and to determine where ammonia decreases may increase the acidity of particles and precipitation.

The proposal showed consideration for the uncertainties about ammonia emissions inventories and about the potential efficacy of ammonia control measures by providing for a case-by-case approach. It was recommended that each State should evaluate whether reducing ammonia emissions would lead to $PM_{2.5}$ reductions in their specific $PM_{2.5}$ nonattainment areas. The proposed policy did not require States to address ammonia as a $PM_{2.5}$ attainment plan precursor, unless a technical demonstration by the State or EPA showed that ammonia emissions from sources in the State significantly contribute to $PM_{2.5}$ concentrations in a given nonattainment area or to other downwind air quality concerns. Where the State or EPA has determined that ammonia is a significant contributor to $PM_{2.5}$ formation in a nonattainment area, the State would be required to evaluate control measures for ammonia emissions in its nonattainment SIP due in 2008, in the implementation of the PM program, and in other associated programs in that area.

b. Final Rule

In the final rule, ammonia is presumed not to be a $PM_{2.5}$ attainment plan precursor, meaning that the State is not required to address ammonia in its attainment plan or evaluate sources of ammonia emissions for reduction measures. This presumption can be reversed based on an acceptable technical demonstration for a particular area by the State or EPA. If a technical demonstration by the State or EPA shows that ammonia emissions from sources in the State significantly contribute to $PM_{2.5}$ concentrations in a given nonattainment area, the State must then evaluate and consider control strategies for reducing ammonia emissions in its nonattainment SIP due in 2008, in the implementation of the $PM_{2.5}$ program. Technical demonstrations on ammonia should also consider the potential for atmospheric and particle acidity to increase with ammonia reductions. Further discussion about technical demonstrations to

[11] NARSTO (2004) (*Particulate Matter Assessment for Policy Makers:* A NARSTO Assessment. P. McMurry, M. Shepherd, and J. Vickery, eds. Cambridge University Press, Cambridge, England. ISBN 0 52 184287 5.

support reversing a $PM_{2.5}$ precursor presumption is included in section II.A.8 below.

This approach was retained from the proposal because of continued uncertainties regarding ammonia emission inventories and the effects of ammonia emission reductions. Ammonia emission inventories are presently very uncertain in most areas, complicating the task of assessing potential impacts of ammonia emissions reductions. In addition, data necessary to understand the atmospheric composition and balance of ammonia and nitric acid in an area are not widely available across $PM_{2.5}$ nonattainment areas, making it difficult to predict the results of potential ammonia emission reductions. Ammonia reductions may be effective and appropriate for reducing $PM_{2.5}$ concentrations in selected locations, but in other locations such reductions may lead to minimal reductions in $PM_{2.5}$ concentrations and increased atmospheric acidity. Research projects continue to expand our collective understanding of these issues, but at this time EPA believes this case-by-case policy approach is appropriate. In light of these uncertainties, we encourage States to continue efforts to better understand the role of ammonia in its fine particle problem areas.

c. Comments and Responses

Comment: One commenter stated that scientific understanding of the complexities of PM formation from ammonia is limited. The commenter claimed that the reduction of ammonia will not reduce PM in many areas, and speciated PM data to investigate the potential decrease in PM from ammonia emissions reductions is not available in all areas.

Response: The final rule takes these uncertainties into consideration by allowing ammonia to be addressed on a case-by-case basis. For any area about which enough information is available to determine that ammonia emission reductions would lead to a beneficial reduction in $PM_{2.5}$, the State can develop a technical demonstration justifying the control of ammonia. If the State chooses to develop such a demonstration, preferably it should be completed as part of the SIP development process and prior to the adoption of control measures, in consultation with the appropriate EPA regional office.

Comment: Some commenters claimed that requiring no action on some precursors is counter to the requirement in sections 172(a)(2) and 188 to attain the NAAQS as expeditiously as practicable. They also asserted that presuming that ammonia is not a $PM_{2.5}$ attainment plan precursor violates 302(g) by improperly delegating authority to the States.

Response: In many areas, reducing ammonia emissions could have little effect on $PM_{2.5}$ concentrations and could lead to the potentially harmful effect of increased atmospheric acidity. While States are not required to take action on ammonia sources under this policy, States would be required to address information on ammonia brought to their attention during the planning and rule adoption process. Under this approach, States should assess whether ammonia reductions would lead to reduced $PM_{2.5}$ concentrations in specific nonattainment areas. If the State decides that ammonia reductions could yield beneficial reductions in $PM_{2.5}$, the State should complete a technical demonstration supporting a reversal of the presumption. The EPA does not believe that this approach improperly delegates authority to the States. It establishes a general presumption for all areas through this rulemaking process, and allows for the presumption to be modified by the State or EPA on a case-by-case basis. EPA still retains the ability to make a technical demonstration for any area if appropriate to reverse the presumption and require ammonia to be addressed in its attainment plan.

Comment: Some commenters stated that the results of a large study on air emissions from concentrated animal feeding operations (CAFOs) should be evaluated before requiring control of ammonia in areas where agriculture is alleged to be a major source.

Response: The $15 million national CAFO consent agreement study coordinated by Purdue University will greatly improve ammonia and VOC emissions inventories and our understanding of the impacts of agricultural emissions on particle formation. The EPA recognizes that the agricultural emissions study is expected to provide data for future planning purposes, and we expect that some of the results of the study will not be available in time to be considered in the development of $PM_{2.5}$ State Implementation Plans dues in April 2008. However, if a State believes it has sufficient technical information to warrant regulation of ammonia emissions in their 2008 implementation plans, it may include in its plan a demonstration to reverse the presumption as well as emission reduction measures. The EPA will review each submittal on a case-by-case basis.

Comment: A presumption to not address ammonia will impede certain states (*i.e.* those that have provisions requiring their regulations to be ''no stricter than Federal'' provisions) from regulating ammonia.

Response: This presumptive approach to ammonia will not restrict States from addressing ammonia in their $PM_{2.5}$ attainment plans. If a State has information indicating that reductions in ammonia emissions would cause beneficial reductions in $PM_{2.5}$ concentrations, the State can make a technical demonstration to reverse the presumption. In such cases, inclusion of ammonia as a $PM_{2.5}$ attainment plan precursor would not be considered stricter than Federal requirements. Under the policy in the final rule, the Federal government or the State may assess the impact of ammonia in a particular area and determine whether the presumption of insignificance is appropriate or whether ammonia is in fact a significant contributor to the $PM_{2.5}$ problem in the area.

4. Policy for VOC

[Section II.E.2 of November 1, 2005 proposed rule (70 FR 65999); sec. 51.1002 in draft and final regulatory text.]

a. Background

The VOC policy in this rule addresses volatile and semivolatile organic compounds, generally up to 24 carbon atoms. High molecular weight organic compounds (typically 25 carbon atoms or more) are emitted directly as primary organic particles and exist primarily in the condensed phase at ambient temperatures. Accordingly, high molecular weight organic compounds are to be regulated as primary $PM_{2.5}$ emissions for the purposes of the $PM_{2.5}$ implementation program.

The organic component of ambient particles is a complex mixture of hundreds or even thousands of organic compounds. These organic compounds are either emitted directly from sources (i.e. primary organic aerosol) or can be formed by reactions in the ambient air (i.e. secondary organic aerosol, or SOA). Volatile organic compounds are key precursors in the formation processes for both SOA and ozone. The relative importance of organic compounds in the formation of secondary organic particles varies from area to area, depending upon local emissions sources, atmospheric chemistry, and season of the year.

The lightest organic molecules (i.e., molecules with six or fewer carbon atoms) occur in the atmosphere mainly as vapors and typically do not directly

form organic particles at ambient temperatures due to the high vapor pressure of their products. However, they participate in atmospheric chemistry processes resulting in the formation of ozone and certain free radical compounds (such as the hydroxyl radical [OH]) which in turn participate in oxidation reactions to form secondary organic aerosols, sulfates, and nitrates. These VOCs include all alkanes with up to six carbon atoms (from methane to hexane isomers), all alkenes with up to six carbon atoms (from ethene to hexene isomers), benzene and many low-molecular weight carbonyls, chlorinated compounds, and oxygenated solvents.

Intermediate weight organic molecules (i.e., compounds with 7 to 24 carbon atoms) often exhibit a range of volatilities and can exist in both the gas and aerosol phase at ambient conditions. For this reason they are also referred to as semivolatile compounds. Semivolatile compounds react in the atmosphere to form secondary organic aerosols. These chemical reactions are accelerated in warmer temperatures, and studies show that SOA typically comprises a higher percentage of carbonaceous PM in the summer as opposed to the winter. The production of SOA from the atmospheric oxidation of a specific VOC depends on four factors: Its atmospheric abundance, its chemical reactivity, the availability of oxidants (O_3, OH, HNO_3), and the volatility of its products. In addition, recent work suggests that the presence of acidic aerosols may lead to an increased rate of SOA formation. Aromatic compounds such as toluene, xylene, and trimethyl benzene are considered to be the most significant anthropogenic SOA precursors and have been estimated to be responsible for 50 to 70 percent of total SOA in some airsheds. Man-made sources of aromatics gases include mobile sources, petrochemical manufacturing and solvents. Some of the biogenic hydrocarbons emitted by trees are also considered to be important precursors of secondary organic particulate matter. Terpenes (and b-pinene, limonene, carene, etc.) and the sesquiterpenes are expected to be major contributors to SOA in areas with significant vegetation cover, but isoprene is not. Terpenes are very prevalent in areas with pine forests, especially in the southeastern U.S. The rest of the anthropogenic hydrocarbons (higher alkanes, paraffins, etc.) have been estimated to contribute 5–20 percent to the SOA concentration depending on the area.

The contribution of the primary and secondary components of organic aerosol to the measured organic aerosol concentrations remains a complex issue. Most of the research performed to date has been done in southern California, and more recently in central California, while fewer studies have been completed on other parts of North America. Many studies suggest that the primary and secondary contributions to total organic aerosol concentrations are highly variable, even on short time scales. Studies of pollution episodes indicate that the contribution of SOA to the organic particulate matter can vary from 20 percent to 80 percent during the same day.

Despite significant advances in understanding the origins and properties of SOA, it remains probably the least understood component of $PM_{2.5}$. The reactions forming secondary organics are complex, and the number of intermediate and final compounds formed is voluminous. Some of the best efforts to unravel the chemical composition of ambient organic aerosol matter have been able to quantify the concentrations of hundreds of organic compounds representing only 10–20 percent of the total organic aerosol mass. For this reason, SOA continues to be a significant topic of research and investigation.

Current scientific and technical information clearly shows that carbonaceous material is a significant fraction of total $PM_{2.5}$ mass in most areas, that certain VOC emissions are precursors to the formation of secondary organic aerosol, and that a considerable fraction of the total carbonaceous material is likely from local as opposed to regional sources. However, while significant progress has been made in understanding the role of gaseous organic material in the formation of organic PM, this relationship remains complex. We recognize that further research and technical tools are needed to better characterize emissions inventories for specific VOC compounds, and to determine the extent of the contribution of specific VOC compounds to organic PM mass.

In light of these factors, the proposed rule did not require States to address VOCs as $PM_{2.5}$ attainment plan precursors and evaluate them for control measures, unless the State or EPA makes a finding that VOCs significantly contribute to a $PM_{2.5}$ nonattainment problem in the State or to other downwind air quality concerns. Many $PM_{2.5}$ nonattainment areas are also nonattainment areas for the 8-hour ozone standard; control measures for VOCs will be implemented in some of these areas, potentially providing a co-benefit for $PM_{2.5}$ concentrations.

b. Final Rule

The final rule maintains the same policy as proposed.[12] States are not required to address VOC in $PM_{2.5}$ implementation plans and evaluate control measures for such pollutants unless the State or EPA makes a technical demonstration that emissions of VOCs from sources in the State significantly contribute to $PM_{2.5}$ concentrations in a given nonattainment area. Technical demonstrations are discussed in section II.A.8 below. If a State chooses to make a technical demonstration, it should be developed in advance of the attainment demonstration.

c. Comments and Responses

Comment: One commenter stated that our understanding of the complexities of $PM_{2.5}$ formation from VOCs is limited, that speciated PM data are not available in all areas, and that VOC reductions will not reduce $PM_{2.5}$ in many areas.

Response: The EPA acknowledges the uncertainties regarding the role of VOC in secondary organic aerosol formation. For this reason the final rule does not presumptively include VOC as a regulated pollutant for PM planning. However, if available data demonstrates that control of VOC would reduce $PM_{2.5}$ concentrations in an area, the State or EPA may include VOC as an attainment plan precursor.

Comment: One commenter stated that the rationale that VOC should not be considered a $PM_{2.5}$ attainment plan precursor because most PM areas are also ozone areas is not appropriate because many ozone areas will attain soon and VOC reductions will still be needed for PM.

Response: The primary rationale for not including VOC as a $PM_{2.5}$ attainment plan precursor in every nonattainment area is the uncertainty regarding the contribution of anthropogenic VOCs to the formation of the organic carbon portion of fine particles. In certain areas, EPA expects that VOC control measures will have some co-benefits in the reduction of fine particulates. However, this reason should not be considered the principal reason for the policy in the final rule that VOCs presumptively should not be considered $PM_{2.5}$ attainment plan precursors. If a State or EPA determines that VOCs do contribute significantly to $PM_{2.5}$ concentrations in an area, the State will be required to evaluate control measures for VOC as a $PM_{2.5}$ attainment plan

[12] The policy is the same as proposed, with the clarification regarding downwind areas discussed above (Section A.2.b).

precursor for that area. This approach will provide for regulation of VOCs in locations where it is most appropriate.

Comment: One commenter suggested that EPA wait for the results of the pending agricultural emissions study before requiring control of VOCs in agricultural areas.

Response: The $15 million national CAFO consent agreement study coordinated by Purdue University will greatly improve ammonia and VOC emissions inventories and our understanding of the impacts of agricultural emissions on particle formation. The EPA recognizes that the agricultural emissions study is expected to provide data for future planning purposes, and we expect that some of the results of the study will not be available in time to be considered in the development of $PM_{2.5}$ State Implementation Plans dues in April 2008. However, if a State believes it has sufficient technical information to warrant regulation of VOC emissions in their 2008 implementation plans, it may include in its plan a demonstration to reverse the presumption as well as emission reduction measures. The EPA will review each submittal on a case-by-case basis.

5. Policy for NO_X

[Section II.E.2 of November 1, 2005 proposed rule (70 FR 65999); sec. 51.1002 in draft and final regulatory text.]

a. Background

The sources of NO_X are numerous and widespread. The combustion of fossil fuel in boilers for commercial and industrial power generation and in mobile source engines each account for approximately 30 percent of NO_X emissions in $PM_{2.5}$ nonattainment areas (based on 2001 emission inventory information). Nitrates are formed from the oxidation of oxides of nitrogen into nitric acid either during the daytime (reaction with OH) or during the night (reactions with ozone and water). Nitric acid continuously transfers between the gas and the condensed phases through condensation and evaporation processes in the atmosphere. However, unless it reacts with other species (such as ammonia, sea salt, or dust) to form a neutralized salt, it will volatilize and not be measured using standard $PM_{2.5}$ measurement techniques. The formation of aerosol ammonium nitrate is favored by the availability of ammonia, low temperatures, and high relative humidity. Because ammonium nitrate is semivolatile and not stable in higher temperatures, nitrate levels are typically lower in the summer months and higher in the winter months. The resulting ammonium nitrate is usually in the sub-micrometer particle size range. Reactions with sea salt and dust lead to the formation of nitrates in coarse particles. Nitric acid may be dissolved in ambient aerosol particles.

Based on a review of speciated monitoring data analyses, it is apparent that nitrate concentrations vary significantly across the country. For example, in some southeastern locations, annual average nitrate levels are in the range of 6 to 8 percent of total $PM_{2.5}$ mass, whereas nitrate comprises 40 percent or more of $PM_{2.5}$ mass in certain California locations. Nitrate formation is favored by the availability of ammonia, low temperatures, and high relative humidity. It is also dependent upon the relative degree of nearby SO_2 emissions because ammonia reacts preferentially with SO_2 over NO_X. NO_X reductions are expected to reduce $PM_{2.5}$ concentrations in most areas. However, it has been suggested that in a limited number of areas, NO_X control would result in increased $PM_{2.5}$ mass by disrupting the ozone cycle and leading to increased oxidation of SO_2 to form sulfate particles, which are heavier than nitrate particles. Because of the above factors, the proposed rule presumed that States must evaluate and implement reasonable controls on sources of NO_X in all nonattainment areas, but allowed for the State and EPA to develop a technical demonstration to reverse this presumption.

b. Final Rule

The EPA is retaining the proposed approach in the final rule.[13] Under this policy, States are required to address NO_X as a $PM_{2.5}$ attainment plan precursor and evaluate reasonable controls for NO_X in $PM_{2.5}$ attainment plans, unless the State and EPA make a finding that NO_X emissions from sources in the State do not significantly contribute to $PM_{2.5}$ concentrations in the relevant nonattainment area. This presumptive policy is consistent with other recent EPA regulations requiring NO_X reductions which will reduce fine particle pollution, such as the Clean Air Interstate Rule and a number of rules targeting onroad and nonroad engine emissions.

Technical demonstrations that would reverse the presumption should be developed in advance of the attainment demonstration and are discussed in section II.A.8 below.

[13] The policy is the same as proposed, with the clarification regarding downwind areas discussed above (Section A.2.b).

c. Comments and Responses

Comment: Most commenters generally agreed with the proposed inclusion of NO_X as a presumptive $PM_{2.5}$ attainment plan precursor.

Response: The EPA agrees with these commenters.

Comment: Some commenters requested guidance on what would constitute an acceptable demonstration to reverse the presumption that NO_X is a $PM_{2.5}$ attainment plan precursor.

Response: Guidance on technical demonstrations to reverse the presumptive inclusion of NO_X in all state implementation plans is discussed in section II.A.8 below.

Comment: One commenter raised concerns that the proposed policy for NO_X would allow a State to find NO_X to be an insignificant contributor to an area's $PM_{2.5}$ nonattainment problem and effectively keep the State from controlling the area's NO_X emissions for other purposes, such as to address interstate transport under section 110 of the CAA. Section 110 requires SIPs to prohibit emissions within the State that would contribute significantly to another State's nonattainment problem or interfere with another State's maintenance plan.

Response: The identification of precursors for regulation under this rule is for purposes of $PM_{2.5}$ nonattainment and maintenance plans under Part D of the CAA. The $PM_{2.5}$ implementation rule does not prevent a State from regulating NO_X sources under any other Federal or State rule, including interstate transport rules under Section 110.

6. Policy for SO_2

[Section II.E.2 of November 1, 2005 proposed rule (70 FR 65999); sec. 51.1002 in draft and final regulatory text.]

a. Background

Sulfur dioxide is emitted mostly from the combustion of fossil fuels in boilers operated by electric utilities and other industry. Less than 20 percent of SO_2 emissions nationwide are from other sources, mainly other industrial processes such as oil refining and pulp and paper production. The formation of sulfuric acid from the oxidation of SO_2 is an important process affecting most areas in North America. There are three different pathways for this transformation.

First, gaseous SO_2 can be oxidized by the hydroxyl radical (OH) to create sulfuric acid. This gaseous SO_2 oxidation reaction occurs slowly and only in the daytime. Second, SO_2 can

dissolve in cloud water (or fog or rain water), and there it can be oxidized to sulfuric acid by a variety of oxidants, or through catalysis by transition metals such as manganese or iron. If ammonia is present and taken up by the water droplet, then ammonium sulfate will form as a precipitate in the water droplet. After the cloud changes and the droplet evaporates, the sulfuric acid or ammonium sulfate remains in the atmosphere as a particle. This aqueous phase production process involving oxidants can be very fast; in some cases all the available SO_2 can be oxidized in less than an hour. Third, SO_2 can be oxidized in reactions in the particle-bound water in the aerosol particles themselves. This process takes place continuously, but only produces appreciable sulfate in alkaline (dust, sea salt) coarse particles. Oxidation of SO_2 has also been observed on the surfaces of black carbon and metal oxide particles. During the last 20 years, much progress has been made in understanding the first two major pathways, but some important questions still remain about the smaller third pathway. Models indicate that more than half of the sulfuric acid in the eastern United States and in the overall atmosphere is produced in clouds.

The sulfuric acid formed from the above pathways reacts readily with ammonia to form ammonium sulfate, $(NH_4)_2SO_4$. If there is not enough ammonia present to fully neutralize the produced sulfuric acid (one molecule of sulfuric acid requires two molecules of ammonia), part of it exists as ammonium bisulfate, NH_4HSO_4 (one molecule of sulfuric acid and one molecule of ammonia) and the particles are more acidic than ammonium sulfate. In certain situations (in the absence of sufficient ammonia for neutralization), sulfate can exist in particles as sulfuric acid, H_2SO_4. Sulfuric acid often exists in the plumes of stacks where SO_2, SO_3, and water vapor are in much higher concentrations than in the ambient atmosphere, but these concentrations become quite small as the plume is cooled and diluted by mixing.

Because sulfate is a significant contributor (e.g. ranging from 9 percent to 40 percent) to $PM_{2.5}$ concentrations in nonattainment areas and to other air quality problems in all regions of the country, EPA proposed that States would be required to address sulfur dioxide as a $PM_{2.5}$ attainment plan precursor in all areas.

b. Final Rule

The final rule includes the same policy for sulfur dioxide as in the proposal. States are required to address sulfur dioxide as a $PM_{2.5}$ attainment plan precursor and evaluate SO_2 for possible control measures in all areas. Sulfate is an important precursor to $PM_{2.5}$ formation in all areas, and has a strong regional impact on $PM_{2.5}$ concentrations. This policy is consistent with past EPA regulations, such as the CAIR, the Clean Air Visibility Rule, the Acid Rain rules, and the Regional Haze rule, that require SO_2 reductions to address fine particle pollution and related air quality problems.

Under the transportation conformity program, sulfur dioxide is not required to be addressed in transportation conformity determinations *before* a SIP is submitted unless either the state air agency or EPA regional office makes a finding that on-road emissions of sulfur dioxide are significant contributors to the area's $PM_{2.5}$ problem. Sulfur dioxide would be addressed *after* a $PM_{2.5}$ SIP is submitted if the area's SIP contains an adequate or approved motor vehicle emissions budget for sulfur dioxide. EPA based this decision on the *de minimis* level of sulfur dioxide emissions from on-road vehicles currently, and took into consideration the fact that sulfur dioxide emissions from on-road sources will decline in the future due to the implementation of requirements for low sulfur gasoline (which began in 2004) and for low sulfur diesel fuel (beginning in 2006). For more information, see the May 6, 2005 transportation conformity rule on $PM_{2.5}$ precursors at 70 FR 24283.

c. Comments and Responses

Comment: Most commenters agreed with the proposed policy for SO_2. One commenter stated, ''* * * requiring states to address sulfur dioxide in attainment planning in all areas is consistent with the science of $PM_{2.5}$ formation and essential to effective implementation of the $PM_{2.5}$ NAAQS.'' Another commenter concluded that EPA's proposal ''* * * is justified based on the fact that SO_2 has been found to be a significant contributor to $PM_{2.5}$ nonattainment in all areas.''

Response: The EPA agrees with these comments.

Comment: Some commenters believe States should be able to make a demonstration that SO_2 not be addressed as an attainment plan precursor. The commenters claim that the urban increment of sulfate is generally small, and SO_2 control will not matter in many areas. Commenters also note that a large percentage of the SO_2 emission inventory is being reduced and will be reduced further through existing programs, and that if attainment can be demonstrated without additional SO_2 controls, a State should be allowed to make that demonstration in its SIP. One commenter stated that whether SO_2 emissions from a given source located in a nonattainment area in fact contribute significantly to ambient concentrations of sulfate and $PM_{2.5}$ in that nonattainment area likely will depend on a range of factors, including source type, stack height, location, and meteorology. The commenter asserted that sulfate forms over significant geographic distances from the source of the SO_2 emissions and may not form significant concentrations of $PM_{2.5}$ in the local nonattainment area.

Response: As in the proposal, the final rule requires SO_2 to be considered a $PM_{2.5}$ attainment plan precursor in all cases. Sulfate is a significant fraction of $PM_{2.5}$ mass in all nonattainment areas currently, and although large SO_2 reductions are projected from electric generating units with the implementation of the CAIR program, sulfate is still projected to be a key contributor to $PM_{2.5}$ concentrations in the future. SO_2 emissions also lead to sulfate formation on both regional and local scales. The EPA agrees that the extent of the contribution from a particular source in a nonattainment area to $PM_{2.5}$ concentrations in the area will depend on a number of factors, and that at times the reaction of SO_2 emissions in the atmosphere to form sulfate particles may occur less rapidly and extend over a significant distance. However, at other times the conversion of SO_2 to sulfate can occur rapidly and local impacts from a particular source can be more significant. States are required to develop plans to attain as expeditiously as practicable through the identification of technically and economically feasible control measures from the full range of source categories contributing to $PM_{2.5}$ nonattainment areas. In developing these plans, each State will need to consider whether controls on local SO_2 sources would be cost-effective and would be needed to attain expeditiously.

7. Policy for Direct PM

[Section II.E.2 of November 1, 2005 proposed rule (70 FR 65999); sec. 51.1002 in draft and final regulatory text.]

a. Background

This section addresses inorganic and organic forms of directly emitted PM. Although these direct emissions are by definition not precursors to $PM_{2.5}$, this section is included to provide information on the full range of

components that commonly make up fine particulate matter.

The main anthropogenic sources of inorganic (or crustal) particles are: entrainment by vehicular traffic on unpaved or paved roads; mechanical disturbance of soil by highway, commercial, and residential construction; and agricultural field operations (tilling, planting and harvesting). Industrial processes such as quarries, minerals processing, and agricultural crop processing can also emit crustal materials. While much of these emissions are coarse PM, the size distribution can have a tail of particles smaller than $PM_{2.5}$.

In general, coarse PM is most important close to the source, and not generally a significant contributor to regional scale PM problems. Even so, during certain high wind events, fine crustal PM has been shown to be transported over very long distances.

Emission estimates of mechanically suspended crustal PM from sources within the U.S. are often quite high. However, this PM is often released very close to the ground, and with the exception of windblown dust events, thermal or turbulent forces sufficient to lift and transport these particles very far from their source are not usually present. Thus, crustal material is only a minor part of $PM_{2.5}$ annual average concentrations.

Primary carbonaceous particles are largely the result of incomplete combustion of fossil or biomass fuels. This incomplete combustion usually results in emissions of both black carbon and organic carbon particles. High molecular weight organic molecules (i.e., molecules with 25 or more carbon atoms) are either emitted as solid or liquid particles, or as gases that rapidly condense into particle form. These heavy organic molecules sometimes are referred to as volatile organic compounds, but because their characteristics are most like direct PM emissions, they will be considered to be primary emissions for the purposes of this regulation. Primary organic carbon also can be formed by condensation of semi-volatile compounds on the surface of other particles.

The main combustion sources emitting carbonaceous $PM_{2.5}$ are certain industrial processes, managed burning, wildland fires, open burning of waste, residential wood combustion, coal and oil-burning boilers (utility, commercial and industrial), and mobile sources (both onroad and nonroad). Certain organic particles also come from natural sources such as decomposition or crushing of plant detritus. Most combustion processes emit more organic particles than black carbon particles. A notable exception to this is diesel engines, which typically emit more black carbon particles than organic carbon. Because photochemistry is typically reduced in the cooler winter months for much of the country, studies indicate that the carbon fraction of PM mass in the winter months is likely dominated by direct PM emissions as opposed to secondarily formed organic aerosol.

Particles from the earth's crust may contain a combination of metallic oxides and biogenic organic matter. The combustion of surface debris will likely entrain some soil. Additionally, emissions from many processes and from the combustion of fossil fuels contain elements that are chemically similar to soil. Thus, a portion of the emissions from combustion activities may be classified as crustal in a compositional analysis of ambient $PM_{2.5}$. The proposed rule required that States address the direct emissions of particulate matter in their $PM_{2.5}$ attainment plans. During the comment period, EPA received several comments regarding the definition of what should be regulated as ''direct $PM_{2.5}$.''

b. Final Rule

This rule defines direct $PM_{2.5}$ emissions as ''air pollutant emissions of direct fine particulate matter, including organic carbon, elemental carbon, direct sulfate, direct nitrate, and miscellaneous inorganic material (i.e. crustal material).'' Development of attainment plans will include direct $PM_{2.5}$ emissions and specific $PM_{2.5}$ attainment plan precursors.

c. Comments and Responses

Comment: A few commenters noted that 40 CFR 51.1000 of the proposed rule includes definitions for both ''direct $PM_{2.5}$ emissions'' and for ''$PM_{2.5}$ direct emissions.'' They recommend including just one definition in the final rule.

Response: The EPA acknowledges this oversight and has included in the final rule a single definition for ''direct $PM_{2.5}$ emissions.'' It reads: ''Direct $PM_{2.5}$ emissions means solid particles emitted directly from an air emissions source or activity, or gaseous emissions or liquid droplets from an air emissions source or activity which condense to form particulate matter at ambient temperatures. Direct $PM_{2.5}$ emissions include elemental carbon, directly emitted organic carbon, directly emitted sulfate, directly emitted nitrate, and other inorganic particles (including but not limited to crustal material, metals, and sea salt).''

8. Optional Technical Demonstrations for NO_X, VOC, and Ammonia

[Section II.E.2 of November 1, 2005 proposed rule (70 FR 65999); sec. 51.1002 in draft and final regulatory text.]

a. Background

The proposed rule required States to evaluate and consider control strategies for sources of SO_2 and direct $PM_{2.5}$ emissions in all nonattainment areas. For the precursors NO_X, VOC, and ammonia, the proposed rule included presumptive policies that could be reversed with an acceptable technical demonstration by the State or EPA. (The policy in the proposal presumptively required that NO_X emissions must be addressed in all areas, and that VOC and ammonia emissions do not need to be addressed in all areas.) A number of commenters requested additional guidance on the criteria for an acceptable technical demonstration.

b. Final Rule

The final rule retains provisions for the State or EPA to conduct a technical demonstration to reverse the presumptive inclusion of NO_X or to reverse the presumptive exclusions of ammonia and VOC as $PM_{2.5}$ attainment plan precursors. Demonstrations to reverse the presumptions for ammonia, VOC, or NO_X are to be based on the weight of evidence of available information, and any demonstration by the State must be approved by EPA. The State must demonstrate that based on the sum of available technical and scientific information, it would be appropriate for a nonattainment area to reverse the presumptive approach for a particular precursor. The demonstration should include information from multiple sources, including results of speciation data analyses, air quality modeling studies, chemical tracer studies, emission inventories, or special intensive measurement studies to evaluate specific atmospheric chemistry in an area.

Because of the variation among nonattainment areas in terms of such factors as local emissions sources, growth patterns, topography, and severity of the nonattainment problem, EPA believes that it would not be appropriate to define a prescriptive set of analyses that must be included in all $PM_{2.5}$ precursor technical demonstrations. The key criterion is that any technical demonstration must fairly represent available information.

In developing the implementation plan for a nonattainment area, the State should use all relevant information

available (from EPA, the State, or other sources) to determine the scientifically most appropriate approach to regulating NO_X, ammonia, and VOC emissions in the area. As required under any State rulemaking process, the State must consider and provide a response in the record to any information or evidence brought forward by commenters during the SIP planning, development and review process which indicates that the presumption for a precursor should be reversed. In its review of the forthcoming State implementation plan submittal, EPA will review the State's proposed precursor policies in light of all currently available information. If information brought forward by commenters or the State in the SIP development process shows that the presumption in this rule for ammonia, VOC or NO_X is not technically justified for a particular nonattainment area, the State must conduct a technical demonstration to reverse the presumption. In the case of ammonia or VOC, the State then would evaluate control measures and implement those measures that are technically and economically feasible and that will contribute to expeditious attainment of the standards.

In the section below we suggest examples of the types of analyses that would be appropriate to use in developing such a demonstration. States are encouraged to consult with EPA in formulating appropriate technical demonstrations.

i. *Emission Inventory Information:* An analysis might show that a precursor composes a significant fraction of the emissions inventory in an area and therefore requires greater consideration.

Example: Several stationary sources emitting particular VOCs known to contribute to SOA formation make up a significant portion of the area's VOC inventory. This analysis may be useful in conjunction with other analyses included in a weight of evidence demonstration.

ii. *Speciation Data Information:* Analysis of data from speciation networks might lead a State to determine the relative importance of a precursor to seasonal or yearly average PM concentrations. Individual precursors require different approaches. Collection of new data could be used to understand the impacts of precursors in an area.

Example: Nitrate ion is a large portion of winter average $PM_{2.5}$ mass. Nitrate ion is a major portion of $PM_{2.5}$ mass on the 10 highest $PM_{2.5}$ days in winter in the past 3 years. The days with the highest mass concentrations might be indicative of inversion conditions and/or local impacts, rather than large-scale transport processes. For these reasons, nitrate should be addressed in the $PM_{2.5}$ attainment plan.

Example: Ammonium ion data combined with total calculated nitrate data indicates that reductions in ammonia would reduce PM concentrations without a sharp related increase in particle acidity. PM speciation data shows that PM in the area is generally within 10% of calculated neutralization. In places for which the needed atmospheric data are available to determine whether increased acidity is estimated to lead to negative environmental effects, analysis showing that increased acidity of particles and precipitation would likely result from ammonia reductions would support the presumption against ammonia regulation. Analysis showing that ammonia reductions would be unlikely to increase the acidity of particles and precipitation, and that potential reductions in ammonia would significantly reduce $PM_{2.5}$ levels, would support a technical demonstration to reverse the presumption.

iii. *Modeling Information:* Results of atmospheric modeling may help a State characterize the impacts of potential precursor emission reductions on $PM_{2.5}$ concentrations in an area.

Example: Modeling of SO_2, NO_X, and VOC emission reductions result in lower sulfate and nitrate levels but not lower secondary organic aerosol levels. This likely indicates that VOC reductions are not as vital as reductions of the other precursors.

Example: Modeled reductions of NO_X show a potential increase in sulfate formation through disruption of the ozone cycle. SO_2 reductions may be a better choice than NO_X reductions.

Example: Modeled ammonia reductions show a projected reduction in $PM_{2.5}$ concentrations in selected areas. Although dependant on good quality inventory data, this type of an analysis would indicate that the area is ammonia-limited and that ammonia reductions may be beneficial.

Example: Modeling shows that reductions in SO_2 in the absence of NO_X reductions in an area will not result in a significant $PM_{2.5}$ reduction because more nitrate particles form when less SO_2 is available for particle formation. However, $PM_{2.5}$ reductions are significant when both SO_2 and NO_X are reduced concurrently. This analysis would indicate that NO_X reductions should be included in the $PM_{2.5}$ attainment plan for the area.

iv. *Monitoring, Data Analysis, or Other Special Studies:* Could include monitoring of gases and compounds not typically monitored under the $PM_{2.5}$ speciation network, receptor modeling analysis, or special monitoring studies.

Example: Data from specialized monitoring studies can provide insights about concentrations of ammonia gas and nitric acid in an area and whether the area is ammonia-limited or not. Ammonia reductions in ammonia-limited areas typically yield reductions in $PM_{2.5}$ concentrations. Specialized monitoring and laboratory studies can also assess the relative concentrations of organic compounds and provide insights into the contributions of different anthropogenic and biogenic VOCs to secondary organic aerosol formation.

Example: Receptor modeling and statistical analysis $PM_{2.5}$ speciation monitoring data can indicate relative contributions to $PM_{2.5}$ mass from sources with different chemical ''fingerprints.''

Example: Additional analysis of organic compounds on filters collected through speciation monitoring may reveal insights about the relative degree of carbonaceous material considered to be from fossil fuel combustion as opposed to combustion of ''modern'' material (such as wood or biomass).

c. Comments and Responses

Comment: A number of commenters requested that the final rule include guidance on acceptable technical demonstrations.

Response: The above section includes examples designed to help States formulate appropriate demonstrations. Prescribing specific technical indicators to be used in all areas would ignore the scientific uncertainty inherent in the relationships between precursor emissions and the responses of atmospheric concentrations of $PM_{2.5}$. Therefore, States are encouraged to review available information and consult with EPA in formulating technical demonstrations appropriate to a particular area.

B. No Classification System

1. No Classification System

a. Background

Section 172 of subpart 1 contains the general requirements for SIPs for all nonattainment areas. Section 172(a)(1) states that on or after the date of designation, the Administrator may classify an area for the purpose of applying an attainment date or for some other purpose. Thus, a classification system is allowed under section 172 of the CAA, but is not required for the purposes of implementing a national ambient air quality standard. The CAA also states that EPA may consider certain factors in making a decision concerning classification for areas, such as the severity of nonattainment in such areas, and the availability and feasibility of the pollution control measures that may be needed to achieve attainment. In the proposed rule, EPA provided two implementation approaches for classifying $PM_{2.5}$ nonattainment areas. Under the first approach, there would be no classification system. Under the second approach, a two-tiered classification system would apply, with areas classified as either ''moderate'' or ''serious'' based on specific criteria.

For example, the two classification tiers could be based on the severity of nonattainment (e.g., serious areas would be those with a design value above a specific threshold), or on the attainment date for the area (e.g., serious areas would be those with attainment dates after April 2010). However, any moderate area that needs an attainment date longer than 5 years would be reclassified as serious. This would ensure that areas with a more persistent $PM_{2.5}$ problem are subject to more stringent requirements, even if they are not one of the areas with the highest current design values. For such areas, the State would be required to request reclassification for an area and ensure that the 2008 attainment SIP submission for the area includes all measures needed to meet the serious area requirements. Under the two tiered classification approach, we proposed that serious $PM_{2.5}$ nonattainment areas would be required to meet the more stringent requirements than moderate areas that would be defined in this rulemaking action (e.g., lower thresholds for RACT, fixed percentage reduction for RFP, etc.). For serious areas, the attainment date would be as expeditious as practicable, but no later than 10 years after designation, depending on the year in which the area would be projected to attain considering existing control requirements and the effect of RACM, RACT and RFP.

b. Final Rule

The EPA believes that in the case of $PM_{2.5}$, the no-classification approach is the most appropriate approach. An advantage of this approach is that it provides a relatively simple implementation structure for State implementation of the $PM_{2.5}$ standards, and avoids the need to define a classification system and determine classifications for each area. Without classifications, this rule still requires that that SIPs include all reasonable measures that contribute to achieving attainment as expeditiously as practicable. (Further detail is provided in sections D. and F. below.) Because of differences in the nature and sources of the $PM_{2.5}$ problem in different parts of the country, EPA did not find it appropriate to establish a tiered classification system with increasing control measure requirements. The no-classifications approach provides States with greater flexibility to determine the control strategies that will be most effective and efficient in bringing specific areas into attainment as expeditiously as practicable. In addition, EPA believes that States requesting additional time to attain the standard beyond the initial 5 year attainment date, provided for under Subpart I, will need to adopt additional or more stringent measures to meet their obligations for RACT, RACM and attainment that is as expeditious as practicable. We believe that this addresses the main concerns of those commenters who contend that a two tiered classification system should be implemented.

c. Comments and Responses

Comment: The majority of the commenters who commented on this issue stated that they agreed with EPA's preferred no classification approach. These commenters generally stated that they believed that EPA has the authority not to establish a classification system for $PM_{2.5}$ nonattainment areas. Some commenters stated that it would also be unreasonable, at this point in the process, for EPA to implement a classification scheme for the $PM_{2.5}$ standard. Many commenters support the no classification approach because it provides for a simple implementation structure and/or allows greater implementation flexibility to States, including flexibility to address specific problems related to individual nonattainment areas in the most cost-effective and expeditious manner, rather than through a one size fits all approach. Other commenters stated that they believe that a classification system is not needed because nonattainment areas in the Eastern United States are likely to attain the standard within a timeframe that is consistent with the timeframe established under Subpart 1.

Response: The EPA agrees with these commenters.

Comment: Several commenters disagreed with EPA's preferred approach and agreed with the two tiered classification approach featuring a ''moderate'' and a ''serious'' area classification. These commenters also stated that the threat of reclassification or ''bump up'' to a higher classification was a powerful incentive for areas to attain as expeditiously as practicable. Commenters also indicated that areas needing more time to attain the standard should be required to implement more stringent measures or mandatory measures.

Response: The EPA agrees that areas with more severe nonattainment problems will need to implement more stringent measures to attain. However, EPA does not believe that a classification system is needed to ensure that such measures are implemented. The EPA believes that on balance the no classification approach is the most appropriate classification option for the implementation of the $PM_{2.5}$ standard because of the difference in contributing sources from area to area.

Comment: Several commenters stated that under EPA's preferred approach, each State would be required to submit an attainment demonstration proposing an attainment date that is ''as expeditious as practicable'' for each area. They asserted that to allow States to propose their own attainment dates would invite delay in the process of cleaning up fine particle pollution. These commenters further stated that States would have no incentive to set an attainment date earlier than the outer limit set by EPA, even if it would be practicable to attain the NAAQS sooner.

Response: Section 172 of the CAA requires SIPs to demonstrate attainment as expeditiously as practicable regardless of whether there is a classification system, and under this rule states must justify that their attainment date is as expeditious as practicable considering all reasonable measures. As noted above, EPA believes that States requesting additional time to attain the standard beyond the initial 5 year attainment date will need to adopt additional or more stringent measures to meet their obligations for RACT and RACM and to attain as expeditiously as practicable. More details on the analytical process required for an attainment demonstration is included in section II.F.

Comment: Several commenters stated that the CAA requires regulation of the $PM_{2.5}$ standard under Subpart 4 of Part D. These commenters state that EPA takes the position that it must regulate $PM_{2.5}$ under Subpart 1 of the CAA, which applies to nonattainment areas in general. The commenters state that section 7513, in Subpart 4 of Part D of the CAA, contains specific provisions for classification of particulate matter nonattainment areas, and that EPA must therefore regulate $PM_{2.5}$ under Subpart 4, which requires a moderate and serious area classification system. Other commenters argued that implementation of the $PM_{2.5}$ standard must proceed under Subpart 1 of Part D of Title I of the CAA and cannot be governed by Subpart 4 of Part D, which addresses the implementation of the PM_{10} standard which is a different pollutant than $PM_{2.5}$.

Response: The EPA finds that the $PM_{2.5}$ standard should be implemented under subpart I of the CAA, which is the general provision of the CAA related to NAAQS implementation. Part D of Title I of the CAA sets forth the requirements for SIPs needed to attain the national ambient air quality standards. Part D also includes a general provision under

Subpart I which applies to all NAAQS for which a specific subpart does not exist. Because the $PM_{2.5}$ standards were not established until 1997, the plan provisions found in section 172 of subpart 1 pertaining to plans for nonattainment areas apply. The EPA further agrees with comments stating that subpart 4 on its face applies only to the PM_{10} standard. In general, the emphasis in subpart 4 on reducing PM_{10} concentrations from certain sources of direct $PM_{2.5}$ emissions can be somewhat effective in certain $PM_{2.5}$ nonattainment areas but not in all. Contributions to $PM_{2.5}$ concentrations are typically from a complex mix of sources of primary emissions and sources of precursor emissions which form particles through reactions in the atmosphere. $PM_{2.5}$ also differs from PM_{10} in terms of atmospheric dispersion characteristics, chemical composition, and contribution from regional transport.

2. Rural Transport Classification Option

a. Background

The 8-hour ozone implementation program includes a ''rural transport classification'' for subpart 1 nonattainment areas. In the proposal for this rule we discussed whether an area classification of this type would be appropriate for the $PM_{2.5}$ implementation program in light of the fact that no currently designated $PM_{2.5}$ nonattainment area met the criteria similar to those that apply to rural transport areas under the ozone implementation program.

As addressed in the proposal, a $PM_{2.5}$ nonattainment area would qualify for the ''rural transport'' classification if it met criteria similar to those specified for rural transport areas for the 1-hour ozone standard under section 182(h). Section 182(h) defines ''rural transport'' areas as those areas that do not include, and are not adjacent to, any part of a Metropolitan Statistical Area (MSA) or, where one exists, a Consolidated Metropolitan Statistical Area (CMSA). Section 182(h) further limits the category to those areas whose own emissions do not make a significant contribution to pollutant concentrations in those areas, or in other areas.

As discussed in the preamble to the proposed rule, potential criteria for a State to identify an area for a rural transport classification under the $PM_{2.5}$ program could be similar to the criteria used in the ozone implementation program: A State with a $PM_{2.5}$ ''rural transport'' area would need to (1) demonstrate that the area meets the above criteria, (2) demonstrate using EPA approved attainment modeling that the nonattainment problem in the area is due to the ''overwhelming transport'' of emissions from outside the area, and (3) demonstrate that sources of $PM_{2.5}$ and its precursor emissions within the boundaries of the area do not contribute significantly to $PM_{2.5}$ concentrations that are measured in the area or in other areas.

An area which qualifies for the ''rural transport'' classification would only be required to adopt local control measures sufficient to demonstrate that the area would attain the standard by its attainment date ''but for'' the overwhelming transport of emissions emanating from upwind States. RFP requirements under subpart 1 would still apply to these areas. As with other nonattainment areas, rural transport nonattainment areas would be subject to NSR, transportation conformity, and general conformity requirements. In the proposal we solicited comments on whether it would be appropriate to establish less burdensome NSR requirements in the event that a classification for rural transport areas is adopted in the final rule. The EPA requested comment on whether this type of classification option is needed at all under the $PM_{2.5}$ implementation program.

b. Final Rule

The final rule does not include a rural transport classification. This type of classification was included in the CAA for purposes of implementing the ozone standards because of the phenomenon of the formation of high ozone levels far downwind in very rural locations, including on high elevation mountain peaks. In reviewing the currently designated $PM_{2.5}$ nonattainment areas, it appears that all areas but one are within or adjacent to a metropolitan area (*i.e.* core-based statistical area or consolidated statistical area), and thus would not meet the criteria discussed above. Although $PM_{2.5}$ concentrations are greatly affected by long-range transport of air pollution, it appears that nonattainment areas typically are located in urban areas and include significant local pollutant sources.

c. Comments and Responses

Comment: Several commenters stated that they do not support the adoption of a rural transport classification because it is not needed. Commenters stated that given the criteria for the rural transport classification, which greatly limits its applicability, few if any $PM_{2.5}$ nonattainment areas can qualify for the option. One commenter stated that EPA modeled the rural transport classification after the ''rural transport areas'' provision contained in subpart 2 of the CAA, which applies only to the ozone standard. The commenter further states that neither Subpart 1 nor 4 contain any statutory authority for such a classification.

Response: The EPA believes that it has sufficient statutory authority under the CAA to establish a rural transport classification, but we do not believe that such a classification is needed.

Comment: One commenter generally supported the rural transport concept and the proposed associated requirements, with the addition that data analysis be included as appropriate in the required technical demonstrations in addition to modeling. While no $PM_{2.5}$ area currently meets the requirements for the rural transport classification option, several commenters recommended that it be maintained for potential cases in which the $PM_{2.5}$ standards are made more stringent, or measured air quality in areas change in such a way that areas would qualify for the rural transport classification at a later date.

Response: The EPA does not agree that a rural transport classification is needed. The EPA will re-evaluate the need for such a classification as appropriate.

C. Due Dates and Basic Requirements for Attainment Demonstrations

a. Background

Part D of Title I of the CAA sets forth the requirements for SIPs needed to attain the national ambient air quality standards. Part D includes a general subpart 1 which applies to all NAAQS for which a specific subpart does not exist. The 1990 CAA Amendments do not include any subpart for $PM_{2.5}$ because the $PM_{2.5}$ standards were not yet established. The EPA has determined that for $PM_{2.5}$, the nonattainment area plan provisions found in section 172 of subpart 1 apply.

Section 172(b) of the CAA requires that at the time the Agency promulgates nonattainment area designations, the EPA must also establish a schedule for States to submit SIPs meeting the applicable requirements of section 172(c) and of section 110(a)(2) of the CAA. Nonattainment area designations were finalized in December 2004, and a supplemental notice was issued in April 2005. Consistent with section 172(b) of the CAA, 40 CFR 51.1002 of the proposed rule requires the State to submit its attainment demonstration and SIP revision within 3 years, or by April 2008.

Section 51.1006 of the proposed rule addresses the situation in which an area

is initially designated as attainment/unclassifiable but is later designated as nonattainment based on air quality data after the 2001–2003 period. Under such circumstances, the SIP submittal date would be 3 years from the effective date of the redesignation, and the attainment date would be as expeditiously as practicable but no later than 5 years from the effective date of the redesignation.

The section 172(c) requirements that States are to address under section 172(c) (including RACT, RACM, RFP, contingency measures, emission inventory requirements, and NSR) are discussed in later sections of this document. Section 110(a)(2) of the CAA requires all States to develop and maintain a solid air quality management infrastructure, including enforceable emission limitations, an ambient monitoring program, an enforcement program, air quality modeling, and adequate personnel, resources, and legal authority. Section 110(a)(2)(D) also requires State plans to prohibit emissions from within the State which contribute significantly to nonattainment or maintenance areas in any other State, or which interfere with programs under part C to prevent significant deterioration of air quality or to achieve reasonable progress toward the national visibility goal for Federal class I areas (national parks and wilderness areas). In order to assist States in addressing their obligations regarding regionally transported pollution, EPA has finalized the CAIR to reduce SO_2 and nitrogen oxide emissions from large electric generating units.[14]

To date, few states have submitted a SIP revision addressing the section 110(a)(2) requirements for the purposes of implementing the $PM_{2.5}$ standards. The EPA recognizes that this situation is due in part to the fact that there were a series of legal challenges to the PM standards which were not resolved until March 2002, at which time the standards and EPA's decision process were upheld (see section I.B. for further discussion of past legal challenges to the standards). To address the States' continuing obligation to address the requirements of section 110(a), 40 CFR 51.1002 of the proposed rule also required each State to address the required elements of section 110(a)(2) of the CAA as part of the SIP revision adopting its attainment plan, if it has not already done so. On March 10, 2005, EPA entered into a consent decree with Environmental Defense and American Lung Association concerning EPA's failure to find that States failed to submit SIPs to address the section 110(a)(2) requirements. As a part of that consent decree, by no later than October 8, 2008, EPA is required to publish a notice in the **Federal Register** related to its determinations of whether each State has submitted SIPs for $PM_{2.5}$ that meet the requirements as stated under section 110(a)(2) of the CAA.

b. Final Rule

The final rule maintains the regulatory approach described above.

c. Comments and Responses

There were no comments on this portion of the proposal.

D. Attainment Dates

1. Background on Statutory Requirements

Establishing attainment dates. Section 172(a)(2) states that an area's attainment date ''shall be the date by which attainment can be achieved as expeditiously as practicable, but no later than 5 years from the date such area was designated nonattainment * * *, except that the Administrator may extend the attainment date to the extent the Administrator determines appropriate, for a period no greater than 10 years from the date of designation as nonattainment considering the severity of nonattainment and the availability and feasibility of pollution control measures.''

Since $PM_{2.5}$ designations have an effective date of April 5, 2005, the initial 5-year attainment date for $PM_{2.5}$ areas would be no later than April 5, 2010. For an area with an attainment date of April 5, 2010, EPA would determine whether it had attained the standard by evaluating air quality data from the three previous calendar years (i.e. 2007, 2008, and 2009).

For any areas that are granted the full 5 year attainment date extension under section 172, the attainment date would be no later than April 5, 2015. For such areas, EPA would determine whether they have attained the standard by evaluating air quality data from 2012, 2013, and 2014. Section 51.1004 of the proposed regulations addressed the attainment date requirement. Section 51.1004(b) provided that in their attainment demonstrations, States would propose an attainment date representing attainment as expeditiously as practicable based upon implementation of existing Federal and State measures, and all new reasonable local and intrastate measures. The EPA would approve a particular attainment date based on its review of the attainment demonstration.

Determining Whether an Area Has Attained. The EPA has the responsibility for determining whether a nonattainment area has attained the standard by its applicable attainment date. Section 179(c)(1) of the Act requires EPA to make determinations of attainment no later than 6 months following the attainment date for the area. Under section 179(c)(2), EPA must publish a notice in the **Federal Register** identifying those areas which failed to attain by the applicable attainment date. The statute further provides that EPA may revise or supplement its determination of attainment for the affected areas based upon more complete information or analysis concerning the air quality for the area as of the area's attainment date.

Section 179(c)(1) of the Act provides that the attainment determination for an area is to be based upon an area's ''air quality data as of the attainment date.'' The EPA will make the determination of whether an area's air quality is meeting the $PM_{2.5}$ NAAQS by the applicable attainment date primarily based upon data gathered from the air quality monitoring sites which have been entered into EPA's Air Quality System (AQS) database. No special or additional SIP submittal will be required from the State for this determination.

A $PM_{2.5}$ nonattainment area's air quality status is determined in accordance with appendix N of 40 CFR part 50. To show attainment of the 24-hour and annual standards for $PM_{2.5}$, the most recent three consecutive years of data prior to the area's attainment date must show that $PM_{2.5}$ concentrations over a three-year period are at or below the levels of the standards. A complete year of air quality data, as described in part 50, Appendix N, comprises of all 4 calendar quarters with each quarter containing data from at least 75 percent of the scheduled sampling days. The annual standard for $PM_{2.5}$ is attained when the 3-year average annual mean concentration is less than or equal to 15.05 $\mu g/m^3$. The 24-hour standard for $PM_{2.5}$ is met when the average of 98th percentile values for three consecutive calendar years at each monitoring site is less than or equal to 65.5 $\mu g/m^3$.

The EPA will begin processing and analyzing data related to the attainment of $PM_{2.5}$ areas immediately after the applicable attainment date for the affected areas. Current EPA policy, under 40 CFR part 58, sets the deadline for submittal of air quality data into the AQS database for no later than 90 days after the end of the calendar year.

[14] More information on the Clean Air Interstate Rule (CAIR) is available at: *http://www.epa.gov/cair.*

While EPA may determine that an area's air quality data indicates that an area may be meeting the $PM_{2.5}$ NAAQS for a specified period of time, this does not eliminate the State's responsibility under the Act to adopt and implement an approvable SIP. If EPA determines that an area has attained the standard as of its attainment date, the area will remain classified as nonattainment until the State has requested, and EPA has approved, redesignation to attainment for the area.

In order for an area to be redesignated as attainment, the State must comply with the five requirements listed under section 107(d)(3)(E) of the Act. This section requires that:

—EPA has determined that the area has met the $PM_{2.5}$ NAAQS;
—EPA has fully approved the state's implementation plan;
—The improvement in air quality is due to permanent and enforceable reductions in emissions;
—EPA has fully approved a maintenance plan for the area;
—The State(s) containing the area have met all applicable requirements under section 110 and part D.

2. Establishing Attainment Dates

a. Background

The EPA proposed rule language on attainment dates that closely tracks the statutory language. In the preamble, EPA noted that the attainment date that is as expeditious as practicable should reflect the projected impact of existing national and State programs (e.g. partial implementation of the CAIR rule, final Acid Rain Program, motor vehicle tier II standards and heavy-duty diesel engine standards, NO_X SIP call, State legislation such as Clean Smokestacks bill in North Carolina) as well as additional reasonable measures required for the $PM_{2.5}$ nonattainment SIP.

With respect to its authority to extend an area's date beyond 5 years, EPA stated in the preamble that the State can submit a SIP demonstrating that it is impracticable to attain by the 5-year attainment date: ''As stated previously, under section 172(a)(2)(A), EPA may grant an area an extension of the initial attainment date for a period of one to 5 years. States that request an extension of the attainment date under this provision of the CAA must submit a SIP by April 5, 2008 that includes, among other things, an attainment demonstration showing that attainment within 5 years of the designation date is impracticable. It must also show that the area will attain the standard by an alternative date that is as expeditious as practicable, but in no case later than 10 years after the designation date for the area (i.e. by April 5, 2015 for an area with an effective designation date of April 5, 2005). An appropriate extension in some cases may be only 1 or 2 years—a 5-year extension is not automatic upon request.

The attainment demonstration must provide sufficient information to show that attainment by the initial attainment date is impracticable due the severity of the nonattainment problem in the area, the lack of available control measures, and any other pertinent information related to these statutory criteria. States requesting an extension of the attainment date must also demonstrate that all local control measures that are reasonably available and technically feasible for the area are currently being implemented to bring about expeditious attainment of the standard by the alternative attainment date for the area. The State's plan will need to project the emissions reductions expected due to Federally enforceable national standards, State regulations, and local measures such as RACT and RACM, and then conduct modeling to project the level of air quality improvement in accordance with EPA's modeling guidance. The EPA will not grant an extension of the attainment date beyond the initial 5 years required by section 172(a)(2)(A) for an area if the State has not considered the implementation of all RACM and RACT local control measures for the area (see section III.I for a more detailed discussion of RACT and RACM). The EPA also will examine whether the State has adequately considered measures to address intrastate transport of pollution from sources within its jurisdiction. In attainment planning, States have the obligation and authority to address the transport of pollution from one area of the State to another. Any decision made by EPA to extend the attainment date for an area beyond its original attainment date will be based on facts specific to the nonattainment area at issue and will only be made after providing notice in the **Federal Register** and an opportunity for the public to comment.''

b. Final Rule

We are adopting the approach described above from the proposed rule. We also wish to clarify language that was in the preamble to the proposed rule regarding the criteria for an extension. The preamble stated that attainment date extensions would be based on the two statutory extension criteria—''the severity of nonattainment, and the availability and feasibility of pollution control measures,''—as well as ''other pertinent information which shows that additional time is required for the area to attain the standard.'' The CAA does not include this third clause and the regulatory text for the final rule does not include this third clause. The intent of this language in the preamble to the proposal was that States could include ''other pertinent information'' related to the two statutory criteria.

c. Comments and Responses

Comment: Some commenters expressed concern that EPA's preamble language appeared to assert a new basis for granting extensions not provided by the statute. They said EPA has authority to extend the attainment date under Section 7502(a)(2) based solely on consideration of two enumerated factors: the severity of nonattainment, and the availability and feasibility of control measures.

Response: The EPA agrees that extensions must be based upon the two factors in the statute, which are quite broad. A clarification of the preamble phrase cited by the commenter is provided above. The phrase in question—''any other pertinent information which shows that additional time is required for the area to attain the standard''—refers to information that relates to the two statutory factors.

Comment: One commenter stated that an area should qualify for an extension only if the area will implement stringent local controls, yet still cannot practicably attain by the five-year deadline. The commenter stated that at a minimum, EPA must require states to adopt RACM for both mobile and stationary sources before granting an extension. Another commenter said that given the difficulty many areas will have in meeting the five-year deadline for attainment of the $PM_{2.5}$ NAAQS (and especially in light of the fact that the deadline occurs only 2 years after states are to submit attainment SIPs), EPA should provide maximum flexibility in allowing extensions to the full 10-year period.

Response: The EPA agrees that extensions should be granted only if an area cannot practicably attain within 5 years despite application of all reasonable measures, including RACM. Although some measures can be implemented within a year or two, many measures require a longer period for installation of controls or full program implementation. In light of the limited time period between the SIP submittal deadline and the 5-year date, EPA believes that a significant number of areas may warrant extensions ranging from one to 5 years, with the length of

extension depending on the factors described above.

Comment: One commenter advocated that EPA include in this final rule a determination of those areas for which attainment within 5 years is impracticable. Another commenter advocated that EPA establish guidance based on EPA national modeling conducted last year to establish 2015 as constituting expeditious attainment for certain areas.

Response: The EPA is not determining in this rulemaking the areas that should receive extensions or should receive the maximum 10-year attainment date, for several reasons. First, EPA did not propose such an approach. Therefore, the public has not had the opportunity to comment on the approach or on the technical information on which EPA would make such judgments.

Second, EPA believes that modeling being conducted by the states, with updated inventories and finer grids, will generally provide a more reliable basis for projecting future $PM_{2.5}$ base case levels than national modeling conducted by EPA with older information. State modeling of future year $PM_{2.5}$ levels that has been conducted to date indicates that some areas will start closer or farther from the standard than EPA had projected.

Third, the SIP process provides a forum for states to identify reasonable controls and conduct analyses to determine the appropriate attainment date for an area. This process provides for input from expert stakeholders, the general public, other states which may share the same multi-State nonattainment area, and EPA on decisions regarding controls and attainment dates. At this time, EPA does not have the benefit of this process to inform a judgment as to when areas can practicably attain. States are responsible for developing RACM demonstrations; at this time, EPA lacks the information to conduct a credible RACM demonstration for all $PM_{2.5}$ nonattainment areas.

Fourth, no State commenter advocated that EPA attempt to make these judgments on attainment dates in advance of the State SIP process. The statute gives the states the lead in developing State implementation plans.

Comment: Another commenter recommends that an area should receive an attainment date extension when collectively the following conditions have been met:

- It is proven through modeling that the region is adversely effected by transport of $PM_{2.5}$ emissions from up wind sources beyond that State's control;
- A State has submitted and committed to implementing all Federal $PM_{2.5}$ emission reduction requirements in a timely manner; and,
- The extension concept is approved through the State air agency or through the MPO Interagency Consultation Process at the MPO level if applicable.

Response: This commenter advocates for attainment date extensions without any consideration of reasonable local measures. As stated above, EPA believes that extensions should be granted only if an area cannot practicably attain within 5 years despite application of all reasonable measures, including RACM. Although some measures can be implemented within a year or two, many measures may require a longer period for installation of controls or full program implementation. In light of the limited time period between the SIP submittal deadline and the 5-year date, EPA believes that a significant number of areas may warrant extensions ranging from one to 5 years, with the length of extension depending on the factors described above.

3. Attainment Dates: 1-Year Extensions

a. Background

Subpart 1 provides for States to request two 1-year extensions of the attainment date for a nonattainment area under limited circumstances. Section 172(a)(2)(C) of the CAA provides that EPA initially may extend an area's attainment date for 1 year, provided that the State has complied with all the requirements and commitments pertaining to the area in the applicable implementation plan, and provided that the area has had no more than a minimal number of ''exceedances'' of the relevant standard in the preceding year. Because the $PM_{2.5}$ standards do not have exceedance-based forms but are based on 3-year averaging periods, we interpret the air quality test in 40 CFR 51.1005 to mean that the area would need to have ''clean data'' for the third of the 3 years that are to be evaluated to determine attainment.[15] By this we mean that for the third year, the air quality for all monitors in the area as analyzed in accordance with Appendix N to 40 CFR part 50 each must have an annual average of 15.0 $\mu g/m^3$ or less, and a 98th percentile of 24-hour monitoring values of 65 $\mu g/m^3$ or less in order to qualify for a 1-year extension. (Given the rounding provisions specified in 40 CFR part 50, Appendix N, these criteria would be satisfied if the concentrations before final rounding are less than an annual average of 15.05 $\mu g/m^3$ and a 24-hour value of 65.5 $\mu g/m^3$.)

For example, suppose an area in violation of the annual standard has an attainment date of April 2010, and its annual average for 2007 was 15.8 and for 2008 was 15.6. If the annual average for the area in 2009 is 14.9, then the 3-year average would be 15.4, and it would not have attained the standard. We interpret section 172(a)(2)(C) as allowing the area to submit a request to EPA for a 1-year extension of its attainment date to 2011 (provided the State has also complied with its requirements and commitments) since the 14.9 ambient air quality value in the third year (2009) met the test of being at or below 15.0. Section 51.1005(a) of the proposed regulation addresses the initial 1-year attainment date extension.

The air quality measured in 2010 in conjunction with prior data will determine if the area attains the standard, qualifies for a second 1-year extension, or does not attain the standard. For example, if the area's annual average for 2010 is 14.3, then its 3-year average for 2008–2010 would be 14.9 and it would have met the annual standard.

If the area's annual average for 2010 is 14.9, however, then its 3-year average for 2008–2010 would be 15.1. In this situation the area would not have attained the standard, but the area would meet the air quality test for the second of the 1-year extensions allowed under section 172(a)(2)(C), because the 2010 annual average was at or below 15.0. Section 51.1005(b) of the proposed rule addresses the second 1-year attainment date extension. After obtaining a second 1-year extension, the State would evaluate whether the air quality values in 2011, in conjunction with 2009 and 2010 data, bring the area into attainment.

Pursuant to section 172(a)(2)(C), States must submit additional information to EPA to demonstrate that they have complied with applicable requirements, commitments, and milestones in the implementation plan. This information is needed in order for EPA to make a decision on whether to grant a 1-year attainment date extension. The EPA will not be inclined to grant a 1-year attainment date extension to an area unless the State can demonstrate that it has met important requirements contained in the area's implementation plan. States must demonstrate that: (1) Control measures have been submitted in the form of a SIP revision and substantially implemented to satisfy the requirements of RACT and RACM for the area, (2) the area has made emissions reductions progress that

[15] See section 51.1005 of the proposed regulation.

represents reasonable further progress (RFP) toward attainment of the NAAQS, and (3) trends related to recent air quality data for the area indicate that the area is in fact making progress toward attainment of the standard. Any decision made by EPA to extend the attainment date for an area will be based on facts specific to the nonattainment area at issue, and will only be made after providing notice in the **Federal Register** and an opportunity for the public to comment.

If an area fails to attain the standard by the attainment date, EPA would publish a finding to this effect in accordance with section 179 of the CAA. The area then would be required, within 1 year of publication of this finding, to develop a revised SIP containing additional emission reduction measures needed to attain the standard as expeditiously as practicable.

b. Final Rule

The final rule retains the proposed criteria for states to receive a 1-year attainment date extension for a nonattainment area.

c. Comments and Responses

Comment: A number of commenters supported EPA's ability to grant a 1-year attainment date extension if monitoring data indicate that the $PM_{2.5}$ levels during the most recent year were below 15.05 $\mu g/m^3$.

Response: The EPA agrees with these comments.

Comment: Some commenters recommended that a 1-year extension be provided if the trend line of the area's emissions levels or air quality data projects attainment in the extension year.

Response: The EPA believes that 1-year extensions should be based on air quality data, which can be assessed quickly after the end of the year. Basing such extensions solely on emissions trends would be impractical due to the longer turnaround time needed to evaluate emissions changes affecting a monitor.

Comment: One commenter believes the current requirement is overly stringent and inconsistent with the statute. The commenter believes that EPA's proposed approach incorrectly defines the statutory language referring to a ''minimal number of exceedances'' of the standard in the previous year as ''zero'' exceedances. Alternatively, the commenter suggests EPA could withdraw this provision and provide more detailed guidance giving the Agency and states some flexibility to demonstrate that exceedances were minimal in a given case since nothing in the statute requires the rigid definition of minimal that EPA proposes.

Response: The EPA believes the policy in the final rule is a reasonable application of the statutory language to a standard not based on exceedances. The EPA does not believe it would be appropriate to provide a 1-year extension to an area with air quality data showing it violating the standard over the 3 years prior to the attainment year.

4. Achieving ''Clean Data''

a. Background

Section III.D of the preamble to the proposed rule describes the incentives for attaining the standards prior to April 2008, when SIP submittals are due, or prior to an area's approved attainment date. Areas with design values just over the level of the standard may be able to achieve reductions in the local area or in the State so that, when their effect is considered in combination with reductions achieved under national programs, they may be sufficient to attain the standards before SIPs are due in 2008. For example, if monitoring in a nonattainment area shows that the air quality for 2004–2006 meets the standards, then the area may be subject to reduced regulatory requirements and be redesignated as ''attainment.''

The EPA issued a ''Clean Data'' policy memorandum in December 2004 describing possible reduced regulatory requirements for areas that attain the standards, but have not yet been redesignated as attainment.[16]

b. Final Rule

In the proposed rule, EPA indicated that it had issued this ''Clean Data'' policy to apply for purposes of the $PM_{2.5}$ standards. In this action EPA is finalizing as a rule the statutory interpretation that is embodied in the policy. Section 51.1004(c). The text of the final rule encapsulates the statutory interpretation set forth in the policy. Determinations as to whether individual areas have attained the $PM_{2.5}$ standard and thus qualify for application of the new clean data rule will be made in the context of rulemakings for those individual areas.

The preamble to the proposed rule mistakenly stated that if an area achieved ''clean data,'' it would be ''relieved of the requirements to implement the nonattainment NSR program otherwise required for nonattainment areas, and instead would implement the PSD program.'' The EPA wishes to clarify that the Clean Data Policy does not provide for suspension of the requirements for NSR nor for RACT. The provisions at issue in the Clean Data Policy include the requirements for an attainment demonstration and other related requirements, reasonable further progress, and contingency measures.

c. Comments and Responses

Comment: One commenter stated that EPA has absolutely no authority to waive NSR or any of the CAA's other requirements for nonattainment areas merely because a nonattainment area has 3 years of clean data, nor does EPA have authority to waive mandatory requirements of the CAA such as NSR, RACT, and RFP merely because EPA or the State claims they are not needed for attainment. The commenter believes that the only way that a nonattainment area can cease implementing controls and requirements mandated for such areas is to seek and obtain redesignation to attainment, and demonstrate in the process that the controls and requirements are not needed for maintenance of standards. The CAA has explicit procedures and prerequisites for redesignating nonattainment areas to attainment (CAA sections 107(d)(3)(E) and 175A). The EPA's ''clean data'' proposal would illegally circumvent those requirements.

Response: The Clean Data policy does not waive requirements for NSR nor for RACT. However, EPA believes that ''clean data'' policies for the ozone and fine particle programs are based on a reasonable interpretation of the CAA. The Clean Data Policy is the subject of two EPA memoranda setting forth our interpretation of the provisions of the Act as they apply to areas that have attained the relevant NAAQS. The EPA also finalized the statutory interpretation set forth in the policy in a final rule, 40 CFR 51.918, as part of its Final Rule to Implement the 8-Hour Ozone National Ambient Air Quality Standard—Phase 2 (Phase 2 Final Rule). See discussion in the preamble to the rule at 70 FR 71645–71646 (November 29, 2005). The legal rationale for the Clean Data policy is explained in our Phase 2 Final Rule, in our December 14, 2004 memorandum from Stephen D. Page entitled ''Clean Data Policy for the Fine Particle National Ambient Air Quality Standards'' (Page Memo), and in our May 10, 1995 memorandum from John S. Seitz, entitled ''Reasonable Further Progress, Attainment

[16] Memorandum of December 14, 2004, from Steve Page, Director, EPA Office of Air Quality Planning and Standards to EPA Air Division Directors, ''Clean Data Policy for the Fine Particle National Ambient Air Quality Standards.'' This document is available at: *http://www.epa.gov/pmdesignations/guidance.htm.*

Demonstration, and Related Requirements for Ozone Nonattainment Areas Meeting the Ozone National Ambient Air Quality Standard'' (Seitz memo). We adopt and reiterate those explications here.

The EPA has also explained its rationale for applying the Clean Data policy in rulemaking actions associated with nonattainment areas for the PM_{10} and 1-hour ozone standards. For rulemaking actions applying the Clean Data policy to the PM_{10} standards, see 71 FR 27440 (May 11, 2006) (Weirton, WVA), 71 FR 13021 (March 14, 2006) (Yuma, AZ), 71 FR 6352 (February 8, 2006) (Ajo, AZ). For a discussion of the legal rationale supporting rulemaking actions applying the Clean Data policy to the 1-hour ozone standards, see, for example, 67 FR 49600 (July 31, 2002); 65 FR 37879 (June 19, 2000) Cincinnati-Hamilton, Ohio-Kentucky); 61 FR 20458 (May 7, 1996) (Cleveland Akron-Lorain, Ohio); 66 FR 53094 (October 19, 2001) (Pittsburgh-Beaver Valley, Pennsylvania); 61 FR 31832 (June 21, 1996 (Grand Rapids, Michigan); 60 FR 36723 (July 18, 1995) (Salt Lake and Davis Counties, Utah); 68 FR 25418 (May 12, 2003) (St Louis, Missouri); 69 FR 21717 (April 22, 2004) (San Francisco Bay Area).

The EPA has further elaborated on its legal rationale for the Clean Data Policy in briefs filed in the 10th, 7th, and 9th Circuits, and hereby incorporates those briefs insofar as relevant here. See *Sierra Club* v. *EPA,* No. 95–9541 (10th Cir.), *Sierra Club* v. *EPA,* No. 03–2839, 03–3329 (7th Cir.), *Our Children's Earth Foundation* v. *EPA,* No. 04–73032 (9th Cir.). As stated in the policy, the attainment demonstration, RFP requirements, and contingency measure requirement are designed to bring an area into attainment. Once this goal has been achieved, it is appropriate to suspend the obligation that States submit plans to meet these goals, so long as the area continues to attain the relevant standard. The Tenth, Seventh and Ninth Circuits have all upheld EPA rulemakings applying the Clean Data Policy. See *Sierra Club* v. *EPA,* 99 F. 3d 1551 (10th Cir. 1996); *Sierra Club* v. *EPA,* 375 F. 3d 537 (7th Cir. 2004); *Our Children's Earth Foundation* v. *EPA,* No. 04–73032 (9th Cir. June 28, 2005 (Memorandum Opinion).

The EPA has explained in its memoranda on the Clean Data Policy for $PM_{2.5}$ and for ozone that it is reasonable to interpret the provisions regarding RFP and attainment demonstrations, along with certain other related provisions, as not requiring further submissions to achieve attainment for so long as the area is in fact attaining the standard. Under the policy, EPA is not granting an exemption from any applicable requirement under Part D. Rather, EPA has interpreted these requirements as not applying for so long as the area remains in attainment with the standard. This is not a waiver of requirements that by their terms apply; it is a determination that certain requirements are written so as to be operative only if the area is not attaining the standard.

CAA section 172(c)(2) provides that SIP provisions in nonattainment areas must require ''reasonable further progress.'' The term ''reasonable further progress'' is defined in section 171(1) as ''such annual incremental reductions in emissions of the relevant air pollutant as are required by this part or may reasonably be required by the Administrator for the purpose of ensuring attainment of the applicable NAAQS by the applicable date.'' Thus, by definition, the ''reasonable further progress'' provision requires only such reductions in emissions as are necessary to attain the NAAQS. If an area has attained the NAAQS, the purpose of the RFP requirement will have been fulfilled, and since the area has already attained, showing that the State will make RFP towards attainment will ''have no meaning at that point.'' The EPA's General Preamble for the Implementation of Title I of the Clean Air Act Amendments of 1990 (General Preamble) 57 FR 13498, 13564 (April 16, 1992).

CAA section 172(c)(1), the requirement for an attainment demonstration, provides in relevant part that SIPs ''shall provide for attainment of the [NAAQS].'' The EPA has interpreted this requirement as not applying to areas that have reached attainment. If an area has attained the standard, there is no need to submit a plan demonstrating how the area will reach attainment. In the General Preamble (57 FR 13564), EPA stated that no other measures to provide for attainment would be needed by areas seeking redesignation to attainment since ''attainment will have been reached.'' See also Memorandum from John Calcagni, ''Procedures for Processing Requests to Redesignate Areas to Attainment,'' September 4, 1992, at page 6.

CAA section 172(c)(9) provides that SIPs in nonattainment areas ''[S]hall provide for the implementation of specific measures to be undertaken if the area fails to make reasonable further progress, or to attain the [NAAQS] by the attainment date applicable under this part. Such measures shall be included in the plan revision as contingency measures to take effect in any such case without further action by the State or [EPA].''

This contingency measure requirement is inextricably tied to the reasonable further progress and attainment demonstration requirements. Contingency measures are implemented if reasonable further progress targets are not achieved, or if attainment is not realized by the attainment date. Where an area has already achieved attainment by the attainment date, it has no need to rely on contingency measures to come into attainment or to make further progress to attainment. As EPA stated in the General Preamble:

> ''The section 172(c)(9) requirements for contingency measures are directed at ensuring RFP and attainment by the applicable date.'' 57 FR 13564. Thus these requirements no longer apply when an area has attained the standard.

It is important to note that should an area attain the $PM_{2.5}$ standards based on three years of data, its obligation to submit an attainment demonstration is not waived but is only suspended. If the area then has air quality concentrations in the following year such that the area exceeds the standard for years 2 through 4, then the area's obligation to submit an attainment demonstration is back in effect.

The determination of attainment contemplated by the Clean Data Policy does not purport to be a redesignation, and thus the requirements for redesignation under section 107(d) are not applicable. Nor does the Clean Data Policy avoid or illegally circumvent the redesignation requirements of section 107 of the CAA. All of the requirements for redesignation remain in effect and must be satisfied for an area to be redesignated. *Sierra Club* v. *EPA*, 99 F.3d at 1557–1558. The Clean Data Policy is simply an interpretation of certain provisions of the CAA, whose express purpose is to achieve attainment of the standard, as not requiring SIP revisions to be made by the State for so long as the area continues to attain the standard. The policy does not purport to exempt areas from requirements that are inapplicable only if an area is redesignated to attainment. It interprets certain provisions which are written in such a way as to impose requirements only upon areas that are not attaining the NAAQS, regardless of whether they have been redesignated to attainment. The EPA has not provided for any waiver from statutory requirements that was not provided by Congress. The area at issue remains designated nonattainment, and is subject to the risk that if a violation occurs it will have to

adopt and implement reasonable further progress requirements, contingency measures, and an attainment demonstration, unless it is redesignated to attainment. In order to be redesignated to attainment, however, the area will have to satisfy all of the requirements of section 107(d)(3)(E), including the requirement for a long-term maintenance plan.

While a determination of attainment is not equivalent to a redesignation to attainment, nothing in the Act compels EPA to wait until an area meets all the requirements for redesignation before EPA makes a determination that the area is in attainment with the standard, thereby suspending the requirements for certain provisions related to attainment. Indeed, section 179(c) of the Act requires EPA to make an attainment determination within six months after an area's applicable attainment date whether or not the EPA has made a finding with respect to redesignation. The EPA's interpretation of the Act's provisions not to require, once attainment has been reached, certain plan submissions whose purpose is to assure attainment, is not at odds with the requirements for redesignation. Nor does EPA's construction of the statute adversely impact planning for maintenance. An area that is monitoring attainment, but is still designated as a nonattainment area, retains strong incentives to seek redesignation to attainment, and remains subject to the requirement to demonstrate maintenance in order to be redesignated. For a detailed discussion of the relationship of redesignation requirements and attainment determinations, see the discussions in the EPA briefs in *Our Children's Earth Foundation* v. *EPA*, supra at pp. 43–60., *Sierra Club* v. *EPA* No. 95–9541 (10th Cir.) at 29–43, and *Sierra Club* v. *EPA* Nos. 03–2839, 03–3329 (7th Cir.) at 33–44 which are contained in the docket for this rulemaking.

Comment: A commenter noted that EPA's proposal suggested that areas attaining the standard would be subject to reduced regulatory requirements. The commenter believed that EPA's interpretation should be codified in regulatory form, in order to assure that areas legally meeting the current $PM_{2.5}$ standard and those requesting redesignation be enabled to be redesignated and to benefit from the interpretation through regulation, rather than by guidance or policy.

Response: The EPA has adopted the commenter's suggested approach of codifying its Clean Data Policy interpretation for $PM_{2.5}$ in regulatory form. Section 51.1004(c). As it did for ozone in its Phase II Ozone Implementation Rule, EPA is including in this rulemaking a regulation that encapsulates the statutory interpretation that is embodied in its Clean Data Policy for $PM_{2.5}$, set forth above. As noted in the response to comment above, determinations as to whether individual areas have attained the $PM_{2.5}$ standard and thus qualify for application of the rule will be made in the context of rulemakings for those individual areas. The EPA believes, however, that encapsulating its interpretation in regulatory form will lend clarity and consistency to the process of applying its interpretation.

E. Modeling and Attainment Demonstrations

1. Background

[Section III.F.1 of November 1, 2005 proposed rule (70 FR 66007); sec 51.1007 in draft and final regulatory text]

As noted in the proposal, Section 172(c) requires States with nonattainment areas to submit an attainment demonstration. An attainment demonstration consists of: (1) Technical analyses that locate, identify, and quantify sources of emissions that are contributing to violations of the $PM_{2.5}$ NAAQS; (2) analyses of future year emissions reductions and air quality improvement resulting from already-adopted national and local programs, and from potential new local measures to meet the RACT, RACM, and RFP requirements in the area; (3) adopted emission reduction measures with schedules for implementation; and (4) contingency measures required under section 172(c)(9) of the CAA.

a. Final Rule

The requirements from the proposal are unchanged. Each State with a nonattainment area will be required to submit a SIP with an attainment demonstration that includes analyses supporting the State's proposed attainment date. States must show that the area will attain the standards as expeditiously as practicable and it must include an analysis of whether implementation of reasonably available measures will advance the attainment date.

2. Areas That Need To Conduct Modeling

[Section III.F.2 of November 1, 2005 proposed rule (70 FR 66007)]

a. Background

All nonattainment areas need to submit an attainment demonstration, but in some cases, States may not need new, local-scale modeling analyses. In the proposed rule, EPA proposed that States may use in a $PM_{2.5}$ attainment demonstration certain local, regional and/or national modeling analyses that have been developed to support Federal or local emission reduction programs, provided the modeling meets the attainment modeling criteria set forth in EPA's modeling guidance. The proposal also stated that nonattainment areas for which local, regional, or national scale modeling demonstrates the area will not attain the standard within 5 years of designation would be required to submit an attainment demonstration SIP that includes new modeling showing attainment of the standards as expeditiously as practicable.

b. Final Rule

In the final rule, EPA is reaffirming the potential use of national and/or regional modeling as part of an attainment demonstration. We are also clarifying the types of modeling analyses that may be useful as a ''primary'' modeling analysis and as a ''supplemental'' analysis. The proposal suggested that it may be appropriate, in certain circumstances, for a State to submit regional or national modeling as the sole (primary) modeling analysis in its attainment demonstration. This implies that the State would not need to conduct local modeling analyses. We wish to further define the differences between ''national'', ''regional'', and ''local'' modeling analyses. In this context, national analyses are generally those conducted by EPA in support of national or regional rules. Regional and local modeling analyses are generally those conducted by the RPOs and/or States for the purpose of developing State Implementation Plans (SIPs). EPA has conducted national scale modeling for a variety of rules and analyses. Additionally, the RPOs and many States are conducting regional and/or local scale modeling of $PM_{2.5}$ and regional haze across the country. The national scale of the EPA modeling analyses requires basic assumptions concerning local model inputs. Compared to regional or local modeling done by the States and/or RPOs, EPA modeling may, in some cases, use coarser grid resolution, use inventories that are not as refined, and model performance may be highly variable from area to area. For these reasons, national scale modeling may not always be appropriate for local area attainment demonstrations.

Therefore, we believe that regional or local modeling conducted by the States or RPOs is best suited as the primary modeling analysis for a modeled

attainment demonstration. The local modeling is more likely to meet the recommendations contained in EPA's modeling guidance. However, some areas having design values close to the standard may be projected to come into attainment within five years based on modeling analyses of national and regional emission control measures (e.g. CAIR) that are scheduled to occur through 2009. Regional scale modeling for national rules such as the Tier II motor vehicle standards, the Heavy-duty Engine standards, the Nonroad Engine standards, and CAIR indicate major reductions in $PM_{2.5}$ by 2010. A portion of these benefits will occur in the 2006–2009 $PM_{2.5}$ attainment timeframe.

Experience with past ozone attainment demonstrations has shown that the process of performing detailed photochemical grid modeling to develop an attainment demonstration can be very resource intensive for States. The EPA believes that it would be appropriate for States to leverage resources by collaborating on modeling analyses to support SIP submittals, or by making use of recent modeling analyses that are completed prior to the SIP submittal date. For this reason, EPA recognizes that States may use in a $PM_{2.5}$ attainment demonstration certain local, regional and/or national modeling analyses that have been developed to support Federal or local emission reduction programs, provided the modeling meets the attainment modeling criteria set forth in EPA's modeling guidance (described below). As with all SIPs under subpart 1, the State must demonstrate that the area will attain the $PM_{2.5}$ standards as expeditiously as practicable. The judgment of whether the modeling is appropriate for an area should be made by the State(s) and their respective EPA regional office on a case-by-case basis.

c. Comments and Responses

Comment: There were many commenters that agreed that States should be able to use EPA modeling or other national or regional modeling as a modeled attainment demonstration. One commenter recommended that the final rule require States to show that the existing modeling incorporates realistic assumptions, accurately reflects local emissions and trends, and provides adequate model performance for the local nonattainment area.

Response: We agree that national and regional modeling may be used as part of an attainment demonstration as long as it is shown to be applicable to the local area. This is consistent with the proposal where we said that existing modeling should ''meet the attainment modeling criteria set forth in EPA's modeling guidance.'' Part of the analysis to determine if existing modeling meets the criteria in the modeling guidance is to assess whether the modeling incorporates realistic assumptions, accurately reflects local emissions and trends, and provides adequate model performance for the local nonattainment area.

Comment: Some commenters thought States should be able to use EPA modeling in the absence of an analysis of the applicability of the modeling for a local nonattainment area. One commenter said that EPA should determine that States should not have to do any additional modeling analyses if the CAIR modeling showed they were expected to attain the NAAQS by 2010.

Response: While we acknowledge there may be some circumstances in which national or regional modeling would be appropriate to use without local modeling and allow for such use, we disagree that national modeling should be used in support of an attainment demonstration without further analysis of the modeling assumptions for a particular area. National scale modeling may not always be appropriate for local areas. Most often, national scale EPA modeling is best suited for use as a supplemental analysis or as part of a ''weight of evidence'' demonstration. The modeling guidance recommends supplemental analyses for all attainment demonstrations. The guidance specifically recommends the examination of other modeling studies as a supplemental analysis. The EPA modeling as well as other ''non-local'' modeling can be used for this purpose. The ''weight'' of this alternative modeling in an attainment demonstration should be guided by how well the modeling system is suited for the local nonattainment area. States should consult with their EPA regional offices for further guidance and recommendations. As such, we do not believe it to be appropriate to determine a priori that CAIR or any other modeling analyses are appropriate to use in a local attainment demonstration for any or all nonattainment areas.

Comment: Several commenters believe that States should be able to use existing EPA modeling (such as CAIR), as the basis for an extension of the area's attainment date, if it shows that the nonattainment area may not be able to attain the NAAQS by 2010. They believe that the State should not have to do additional modeling to show that they need an attainment date extension.

Response: We disagree with this comment. The CAIR modeling included national controls that are expected to be in place by 2010 (including the CAIR rule itself), as well as existing state and local controls reflected in the inventory used in the CAIR analysis. It did not include any additional local controls that could be implemented under RACT and RACM requirements for the 1997 standards that may bring the area into attainment sooner. Nonattainment areas are required to attain the NAAQS as expeditiously as practicable. Therefore, updated modeling of existing controls as well as additional local controls is needed before an attainment date extension can be granted. Additional information on attainment dates and extensions is contained in the preamble to the final rule, section II.D., and additional information on RACT and RACM requirements is contained in section II.F.

Comment: Several commenters noted an apparent inconsistency in the language concerning who would be required to perform ''new'' local-scale modeling. First, there are potentially conflicting statements in the proposal when EPA states that areas with an attainment date of 2010 will need to conduct local-scale modeling to project the estimated level of air quality improvement in accordance with EPA's modeling guidance. This conflicts with the proposed ability for States to use existing national or regional modeling as their modeled attainment demonstration. Second, a portion of a sentence was removed from the **Federal Register** version of the notice which differs from the pre-**Federal Register** version. The published version implies that all nonattainment areas would be required to submit new modeling.

Response: We agree that there are inconsistencies in the proposal preamble text. To clarify, new local-scale modeling is required for areas that are not expected to come into attainment by 2010. For other areas, there may be national or regional modeling which may be applicable to the area which shows they are likely to come into attainment. As noted earlier, national scale modeling is best suited for use as a supplemental analysis, but in some cases may be acceptable evidence that an area will attain by 2010.

Additionally, the preamble language in the **Federal Register** contained an error. A portion of a sentence was mistakenly removed, which led to some confusion. The language in the FR notice (FR page 66008) stated ''Nonattainment areas would be required to submit an attainment demonstration SIP that includes new modeling showing attainment of the

standards as expeditiously as practicable. The new modeling will need to include additional emissions controls or measures in order to demonstrate attainment.'' The language should have read, ''Nonattainment areas *for which local, regional, or national scale modeling demonstrates the area will not be in attainment of the NAAQS within 5 years of designation* would be required to submit an attainment demonstration SIP that includes new modeling showing attainment of the standards as expeditiously as practicable. The new modeling will need to include additional emissions controls or measures in order to demonstrate attainment.'' This should clarify that States that cannot show attainment within 5 years will need to develop new modeling analyses which contain additional control strategies which show how and when they expect to attain the $PM_{2.5}$ NAAQS.

Comment: One commenter maintained that relying on large-scale regional modeling alone may allow for $PM_{2.5}$ hot spots (i.e. small unmonitored areas projected to exceed the standard) to exist past the attainment date.

Response: We agree that nonattainment areas with potential hotspot issues (relatively high concentrations and/or gradients of primary $PM_{2.5}$) should not rely exclusively on regional modeling. The EPA's attainment demonstration modeling guidance attempts to address several aspects of hotspot issues in both monitored and unmonitored areas [17]. The modeled attainment tests contained in EPA's modeling guidance are primarily monitor based tests. Ambient data is combined with the model predicted relative change in PM components to determine if attainment of the standards is likely in the future. There are several aspects of the attainment test. In most cases, States will run a photochemical grid model to determine the future year predicted $PM_{2.5}$ concentrations at monitors. The modeling guidance generally recommends that for urban scale $PM_{2.5}$ modeling, the State performs modeling analyses at 12 kilometer grid resolution or finer. There is an additional component to the attainment test for areas that have measured relatively high concentrations and/or gradients of primary $PM_{2.5}$ at monitors. In these cases, we recommend running a Gaussian dispersion model for potential primary PM sources, to determine the local impact of changes in primary PM emissions (from the modeled sources) on predicted concentrations at the monitor(s).

In addition, we describe an ''unmonitored area analysis'' which uses interpolated ambient data combined with gridded model outputs to examine whether potential violations of the NAAQS may occur in unmonitored areas. If potential violations are indicated, we recommend further analysis of the problem through additional local modeling. Options for State action to address such a situation could include imposition of reasonably available control technology to reduce emissions, or the deployment of an air quality monitor to further characterize the problem.

We believe that the combination of these model-based tests will adequately determine whether attainment of the standards is likely by the attainment date. We also believe that these tests address the issue of hotspots by recommending a combination of photochemical modeling, dispersion modeling of local sources, and additional monitoring and/or emissions controls.

3. Modeling Guidance

[Section III.F.3 of November 1, 2005 proposed rule (70 FR 66008)]

a. Background

Section 110(a)(2)(K)(i) states that SIPs must contain air quality modeling as prescribed by the Administrator for the purpose of predicting the effect of emissions on ambient air quality. The procedures for modeling $PM_{2.5}$ as part of an attainment SIP are contained in EPA's ''Guidance for Demonstrating Attainment of Air Quality Goals for $PM_{2.5}$ and Regional Haze.'' The proposal summarized several of the chapters in a draft version of the modeling guidance.

b. Final Rule

A draft of the $PM_{2.5}$ attainment demonstration and regional haze modeling guidance has now been revised (September 2006) and is available at *http://www.epa.gov/ttn/scram/guidance_sip.htm*. The draft $PM_{2.5}$ attainment demonstration and regional haze guidance has been incorporated into the ozone modeling guidance and is now called ''Guidance on the Use of Models and Other Analyses for Demonstrating Attainment of Air Quality Goals for the 8-Hour Ozone and $PM_{2.5}$ NAAQS and Regional Haze''. The final version of the modeling guidance will be available at the same location in the near future.

The revised draft $PM_{2.5}$ modeling guidance document is very similar to the previous draft version, although there were several changes and updates. Among them are new methods in treating $PM_{2.5}$ species components as part of the $PM_{2.5}$ attainment test; new methods for determining potential future year violations in unmonitored areas; new procedures for handling potential $PM_{2.5}$ ''hotspots''; and an increased reliance on supplemental analyses, including ''weight of evidence'' analyses. The EPA notes that the $PM_{2.5}$ attainment demonstration modeling guidance that we have released is separate from the Agency's future hot-spot modeling guidance for transportation conformity purposes.[18]

The modeling guidance describes how to estimate whether a control strategy to reduce emissions of particulate matter and its precursors will lead to attainment of the annual and 24-hour $PM_{2.5}$ NAAQS. Part I of the guidance describes a ''modeled attainment test'' for the annual and 24-hour $PM_{2.5}$ NAAQS. Both tests are similar. The output of each is an estimated future design value consistent with the respective forms of the NAAQS. If the future design value does not exceed the concentration of $PM_{2.5}$ specified in the NAAQS, then the primary modeled test is passed. The modeled attainment test applies to locations with monitored data.

A separate test is recommended to examine projected future year $PM_{2.5}$ concentrations in unmonitored locations.[19] Interpolated $PM_{2.5}$ ambient data, combined with modeling data, is used to predict $PM_{2.5}$ concentrations in unmonitored areas. The goal of this analysis is to identify areas without monitors that may be violating the $PM_{2.5}$ NAAQS, often due to high levels of primary $PM_{2.5}$ (both now and in the future). The details of the analysis are contained in the final modeling guidance.

The guidance also discusses modeling $PM_{2.5}$ at monitors where high concentrations of primary $PM_{2.5}$ are measured. In these cases, it may be beneficial to model the primary component of the $PM_{2.5}$ with a Gaussian dispersion model. Dispersion models are better able to capture the influence

[17] The recommendations contained in the modeled attainment demonstration guidance are separate from the Agency's future hot-spot modeling guidance for transportation conformity purposes.

[18] In the March 10, 2006, final transportation conformity rule (71 FR 12468), EPA committed to develop $PM_{2.5}$ and PM_{10} quantitative hot-spot modeling guidance for transportation conformity determinations for highway and transit projects of local air quality concern.

[19] Application of the unmonitored area analysis is limited to locations which are appropriate to allow the comparison of predicted $PM_{2.5}$ concentrations to the NAAQS, based on $PM_{2.5}$ monitor siting requirements and recommendations.

of primary PM sources where large concentration gradients may exist. Grid models spread out the PM emissions to the size of the grid (typically 4 or 12 km). This makes it difficult to judge the benefits of control strategies that may affect primary PM sources. The final modeling guidance recommends procedures for applying dispersion models in these situations.

The guidance also recommends the submittal of supplemental analyses as part of all attainment demonstrations. Supplemental analyses are modeling, emissions, and/or ambient data analyses that are submitted as part of a SIP, in addition to the primary modeled attainment test. The evaluation of supplemental analyses when the predicted concentrations in the primary attainment test are close to the NAAQS (slightly above or slightly below) is called a weight-of-evidence (WOE) analysis. This is simply a collection of evidence that aims to show that attainment of the standard is likely. The final version of the modeling guidance puts more emphasis on the submittal of supplemental analyses than in previous versions.

Part II of the guidance describes how to apply air quality models to generate results needed by the modeled tests for attainment. This includes developing a conceptual description of the problem to be addressed; developing a modeling/analysis protocol; selecting an appropriate model to support the demonstration; selecting appropriate meteorological episodes or time periods to model; choosing an appropriate area to model with appropriate horizontal/vertical resolution; generating meteorological and air quality inputs to the air quality model; generating emissions inputs to the air quality model; evaluating performance of the air quality model; and performing diagnostic tests. After these steps are completed, the model is used to simulate the effects of candidate control strategies.

Comment: Several commenters were supportive of the weight of evidence concept. They said that $PM_{2.5}$ modeling is inherently more uncertain than previous ozone modeling and the modeling guidance should reflect that. One commenter noted that weight of evidence demonstrations should be ''unbiased'', meaning that States should use all relevant analyses and not only information that helps their case.

Response: The EPA agrees with these comments. The final modeling guidance recommends supplemental analyses (including weight of evidence) for all attainment demonstrations. All States should submit modeling, ambient data, and emissions analyses in addition to the primary modeling demonstration. A weight of evidence analysis is needed if the predicted future year $PM_{2.5}$ concentrations are slightly higher or slightly lower than the NAAQS.

We also agree that a weight of evidence demonstration should include all relevant information, including analyses which support attainment and those that do not. The idea of the analysis is to ''weigh'' the evidence, both good and bad. That cannot be fairly done if some evidence is not presented.

Comment: Several commenters suggested that a modeled attainment demonstration should not be specifically required. Instead they suggest that all demonstrations should be weight of evidence demonstrations. This would include different analyses of ambient data, trends, and modeling. But due to the uncertainties in the current $PM_{2.5}$ models and emissions data, modeling would be but one part of a broader weight of evidence approach.

Response: We disagree with this comment. Model results should be the primary analysis of an attainment demonstration. Regardless of current uncertainties in the $PM_{2.5}$ models and emissions, models are the only tool that can predict future concentrations of $PM_{2.5}$. The uncertainties in the model inputs and formulation should be taken into account when evaluating the results. We agree that a broad analysis of modeling, ambient data and emissions trends should be part of the attainment demonstration. This is reflected in the final modeling guidance.

4. Modeled Attainment Test

[Section III.F.4 of November 1, 2005 proposed rule (70 FR 66008)]

a. Background

The proposal described the nature of the attainment tests for the annual average and 24-hour average $PM_{2.5}$ NAAQS contained within the modeling guidance. Both tests use monitored data to estimate current air quality. The attainment test for a given standard is applied at each monitor location within or near a designated nonattainment area for that standard. There is also an additional attainment test to be performed in unmonitored areas. Models are used in a relative sense to estimate the response of measured air quality to future changes in emissions. Future air quality is estimated by multiplying current monitored values times modeled responses to changes in emissions. Because $PM_{2.5}$ is a mixture of chemical components, the guidance recommends using current observations and modeled responses of major components of $PM_{2.5}$ to estimate future concentrations of each component. The predicted future concentration of $PM_{2.5}$ is the sum of the predicted component concentrations.

b. Final Rule

The nature of the $PM_{2.5}$ attainment tests is unchanged. The final modeling guidance recommends refinements to the test and discusses the treatment of individual $PM_{2.5}$ species. The speciated modeled attainment test (SMAT) that was used to estimate future $PM_{2.5}$ concentrations for CAIR has been (mostly) implemented in the final guidance. Among the new recommendations is to better account for the known differences between the $PM_{2.5}$ Federal Reference Method (FRM) measurements and the $PM_{2.5}$ speciation measurements. For example, it is recommended to account for the volatilization of nitrate from the FRM filters and to account for uncertainties in organic carbon measurements by employing an ''organic carbon by mass balance'' technique. This assumes that all remaining mass not accounted for by other species is organic carbon mass. Additional details are contained in the modeling guidance.

The guidance also recommends, where necessary, to spatially interpolate $PM_{2.5}$ species data to estimate the species concentrations at FRM sites. It is necessary to estimate species concentrations when there are no species measurements at FRM sites. Several techniques can be used to estimate species concentrations. Spatial interpolation techniques may be useful in many areas. In other cases, it may be adequate to assume that data from a speciation monitor may be representative of multiple FRM monitors. It is particularly important to develop credible techniques to estimate species concentrations at the locations of the highest FRM monitors.

The guidance lists several techniques that can be used. The EPA will provide software which will apply the modeled attainment test, using ambient data and model outputs. Additionally, the software will interpolate the $PM_{2.5}$ species data to allow application of SMAT for all FRM monitors. The software will be available at the same location as the final modeling guidance (*http://www.epa.gov/scram001/guidance_sip.htm*).

Ultimately, it is up to the States to determine the best method to represent the $PM_{2.5}$ species concentrations, subject to EPA's review and approval. These estimates are needed to perform the modeled attainment test.

c. Comments and Responses

Comment: Several commenters were concerned that interpolation of $PM_{2.5}$ species concentrations may not be appropriate in certain areas or situations. The concentrations can vary significantly between urban and rural areas and even between nearby urban areas. One commenter suggested that it might be useful to use older field study measurements to derive current species concentrations. Another commenter suggested that it might be reasonable to assume that speciation measurements were representative of nearby FRM sites.

Response: We agree that interpolations of species data may not always be the best way to estimate species concentrations at FRM sites. The modeling guidance lists several different possible techniques. States should review their data and situation and choose the most reasonable methodology to estimate species concentrations. Nonattainment areas that don't have speciation measurements at the highest FRM site(s) need to be especially careful. The result of the speciated attainment test can be heavily influenced by the assumed species concentrations at the highest FRM sites. The attainment test will be more straightforward in areas with speciation monitors at the highest FRM sites. States are also encouraged to place speciation monitors at the highest FRM sites. This will aid in future assessments of attainment and ambient trends.

5. Multi-Pollutant Assessments

[Section III.F.5 of November 1, 2005 proposed rule (70 FR 66009)]

a. Background

The formation and transport of $PM_{2.5}$ is in many cases closely related to the formation of both regional haze and ozone. There is often a positive correlation between measured ozone and secondary particulate matter. Many of the same factors affecting concentrations of ozone also affect concentrations of secondary particulate matter. For example, similarities exist in sources of precursors for ozone and secondary particulate matter. Emissions of NO_X may lead to formation of nitrates as well as ozone. Sources of VOC may be sources or precursors for both ozone and organic particles. Presence of ozone itself may be an important factor affecting secondary particulate formation. The proposal recommended multi-pollutant assessments for $PM_{2.5}$ attainment demonstrations. A multi-pollutant assessment, or one-atmosphere modeling, is conducted with a single air quality model that is capable of simulating transport and formation of multiple pollutants simultaneously. This type of model simulates the formation and deposition of $PM_{2.5}$, ozone, and regional haze components, and it includes algorithms simulating gas phase chemistry, aqueous phase chemistry, aerosol formation, and acid deposition.

b. Final Rule

The recommendation to conduct multi-pollutant assessments remains unchanged. It is recommended to model the impacts of future year control strategies on $PM_{2.5}$, ozone, and regional haze. It may not always be possible or convenient to do so, but it can be beneficial to the strategy development process.

$PM_{2.5}$ control strategies will have an impact on regional haze, and will possibly impact ozone. Even if high ozone and high $PM_{2.5}$ concentrations don't typically occur during the same time of the year, controls that affect precursors to $PM_{2.5}$ may also affect ozone (e.g. NO_X). The SIP submittal dates for $PM_{2.5}$, ozone, and regional haze do not currently line up. The $PM_{2.5}$ SIPs are due almost 1 year later than ozone. But States can still do modeling analyses that can provide information for multiple pollutants. States can use one-atmosphere models that are capable of simulating both ozone and $PM_{2.5}$. They can also try to use consistent meteorological fields and emissions inventories so that the same control strategies are relatively easy to evaluate for both ozone and $PM_{2.5}$. Modeling the same future year(s) for $PM_{2.5}$ and ozone can also make it easier to evaluate the impacts of controls on both pollutants.

It should be noted that there are no specific modeling requirements other than the recommendation to try to harmonize the ozone, $PM_{2.5}$, and regional haze analyses whenever possible.

c. Comments and Responses

Comment: One commenter suggests that multi-pollutant assessments may not be beneficial because their area experiences winter $PM_{2.5}$ exceedances and summer ozone exceedances.

Response: We disagree with the comment. Even in situations where high $PM_{2.5}$ and ozone don't occur during the same time of year, multi-pollutant assessments may be helpful. NO_X controls that may be needed to reduce nitrates in the winter are likely to have an impact on ozone in the summer. As well, changes in VOCs may have an impact on both $PM_{2.5}$ and ozone. Running potential control strategies through the same modeling platform for ozone, $PM_{2.5}$, and regional haze may allow the development of optimized strategies.

6. Which Future Year(s) Should Be Modeled?

[Section III.F.6 of November 1, 2005 proposed rule (70 FR 66009)]

a. Background

Modeling analyses consist of base year modeling and future year modeling. The attainment test examines the change in air quality between the base and future years. The proposal recommended, where possible, future modeling years should be coordinated so that a single year can be used for both $PM_{2.5}$ and ozone modeling. This coordination will help to reduce resources expended for individual modeling applications for $PM_{2.5}$ and ozone and will facilitate simultaneous evaluation of ozone and PM impacts.

Although there is some flexibility in choosing the future year modeling time periods, unless the State believes it cannot attain the standards within 5 years of the date of designation and must request an attainment date extension, the choice of modeling years for $PM_{2.5}$ cannot go beyond the initial 5 attainment period. Attainment date extensions will only be granted under certain circumstances. Among other things, the State must submit an attainment demonstration showing that attainment within 5 years of the designation date is impracticable.

b. Final Rule

Further information is now known concerning the modeling years for ozone. Moderate nonattainment areas are presumed to be modeling 2009. This is consistent with the last year of the 5 year period allowed under Subpart I for $PM_{2.5}$. Therefore, it is logical to presume that areas that are able to attain the $PM_{2.5}$ NAAQS within 5 years will model a future year of 2009. Areas that won't be able to attain the standard in 5 years will need to request an attainment date extension (of up to 5 additional years).

The NAAQS must be attained as expeditiously as practicable. Therefore, attainment date extensions must contain modeling analyses to justify the extension. Details of the required analyses are contained in the RACT and RACM sections of the final rule. See section F for more details.

F. Reasonably Available Control Technology and Reasonably Available Control Measures

This section of the preamble discusses the final rule requirements for RACT and RACM. In order to explain EPA's

approach in the final rule more clearly, we first discuss the statutory and regulatory background for the RACT and RACM requirements, and we then explain the key options and interpretations upon which we took comment in the proposal. Thereafter, we discuss significant comments we received on the proposal and provide brief responses to those comments. [Additional comments and responses appear in the RTC for this final rule located in the docket.] Most of the comments received on this topic addressed the three options EPA proposed for the RACT requirement, the relationship between the RACT requirement and EPA's Clean Air Interstate Rule (CAIR), and the control measures to be required or considered for RACT and RACM.

1. Background on Statutory Requirements for RACT and RACM

Subpart 1 of Part D of the CAA (sections 171–179B) applies to all designated nonattainment areas. Section 172 of this subpart includes general requirements for all attainment plans.

Notably, Congress provided EPA and States a great deal of deference for determining what measures to include in an attainment plan. Specifically, Section 172(c)(1) requires that each attainment plan ''provide for the implementation of all reasonably available control measures as expeditiously as practicable (including such reductions in emissions from existing sources in the area as may be obtained through the adoption, at a minimum, of reasonably available control technology), and shall provide for attainment of the national primary ambient air quality standards.'' By including language in Section 172(c)(1) that only ''reasonably available'' measures be considered for RACT/RACM, and that implementation of these measures need be applied only ''as expeditiously as practicable,'' Congress clearly intended that the RACT/RACM requirement be driven by an overall requirement that the measure be ''reasonable.'' Thus, the rule of ''reason'' drives the decisions on what controls to apply, what should be controlled, by when emissions must be reduced, and finally, the rigor required in a State's RACT/RACM analysis. For example, we previously stated that the Act ''does not require measures that are absurd, unenforceable, or impractical'' or result in ''severely disruptive socioeconomic impacts'' 55 FR 38327. Moreover, we interpret the term ''reasonably available'' to allow States to consider both the costs and benefits of applying the measure, and whether the measure can be readily and effectively implemented without undue administrative burden. 66 FR 26969.

We also interpret the ''reasonably available control measures'' in these provisions as referring to measures of any type that may be applicable to a wide range of sources, whereas the parenthetical reference to ''reasonably available control technology'' refers to measures applicable to stationary sources. RACM can apply to mobile sources, areas sources and stationary sources not already subject to $PM_{2.5}$ RACT requirements. Thus, RACT is a type of RACM specifically designed for stationary sources. As noted above, States are required to implement RACM and RACT ''as expeditiously as practicable'' as part of attainment plans designed to attain the standards.[20]

Section 172 does not include any specific applicability thresholds to identify the size of sources that States and EPA must consider in the RACT and RACM analysis. Nor, does Section 172 specifically indicate which pollutant(s) or precursor(s) must be subject to RACM or RACT measures to attain the NAAQS. Other pollutant-specific provisions of the CAA do include applicability thresholds pertaining to attainment plan requirements for NAAQS and precursor pollutants. For example, subpart 2 of part D, which establishes additional requirements for ozone nonattainment areas, establishes thresholds ranging from 100 to 10 tons per year for requirements applicable to ''major sources'' or ''major stationary sources,'' depending on the area's classification or level of nonattainment. Subpart 4 of part D, which provides additional plan requirements for PM_{10} nonattainment areas, establishes thresholds of 100 and 70 tons per year for requirements applicable to a ''major source'' or ''major stationary source.''

Moreover, subpart 1, unlike subparts 2 and 4, does not identify specific source categories for which EPA must issue control technology documents or guidelines, or identify specific source categories for State and EPA evaluation during attainment plan development. For ozone, subpart 2 contains a list of specific requirements for control techniques guidelines (CTGs) and alternative control techniques (ACT) documents. For PM_{10}, section 190 of the CAA (in subpart 4) places particular emphasis on specific sources of area emissions, but does not identify specific stationary source categories for which RACT guidance must be issued. Section 190 requires EPA to develop RACM guidance documents for residential wood combustion, silvacultural and agricultural burning, and for urban fugitive dust control.

2. What Is the Overall Approach To Implementing RACT and RACM in the Final Rule?

a. Background for RACT

Since the 1970s, EPA has interpreted RACT to mean ''the lowest emissions limitation that a particular source is capable of meeting by the application of control technology that is reasonably available considering technological and economic feasibility'' as well as other considerations.[21] Presumptive RACT has been described as the norm achievable by the source category.[22]

Section 110 of the 1970 Clean Air Act required States to develop SIPs providing for attainment of the NAAQS by 1975 or 1977. A number of areas were having difficulty with developing attainment plans, particularly for the ozone standard. In response to the implementation needs of this time period, EPA introduced the term ''RACT'' in a 1976 memorandum from Roger Strelow, Assistant Administrator for Air and Waste Management to Regional Administrators, ''Guidance for Determining Acceptability of SIP Regulations in Non-attainment Areas'' (Dec. 9, 1976). In this early guidance relating to the acceptability of SIP regulations, we indicated that our overriding concern in approving SIPs was attaining the particular NAAQS as expeditiously as practicable through reasonably available control technology and other reasonably available control measures. ''The basis for fully approving state-submitted SIP regulations continues to be demonstrated attainment and maintenance of all national ambient air quality standards as expeditiously as practicable,'' the memo stated.

The 1977 Clean Air Act amendments added Part D to Title I of the Act, and for the first time the Act specifically called for EPA to designate nonattainment areas and for SIPs to require RACT and RACM in those nonattainment areas. In a 1979 **Federal**

[20] Under the Tribal Air Rule (TAR), requirements for RACT and RACM may be considered to be severable elements of implementation plan requirements for Tribes.

[21] See, 44 FR 53782, September 17, 1979, and 1976 memorandum from Roger Strelow, Assistant Administrator for Air and Waste Management to Regional Administrators, ''Guidance for Determining Acceptability of SIP Regulations in Non-attainment Areas'' (Dec. 9, 1976).

[22] See e.g. Workshop on Requirements for Non-attainment Area Plans—Compilation of Presentations (OAQPS No. 1.2–103, revised edition April 1978).

Register notice, EPA noted its view that Congress adopted EPA's pre-existing conception of RACT in the 1977 amendments. (44 FR 53782, September 17, 1979). Also during the late 1970s, EPA developed a number of new control techniques guideline (CTG) documents as directed in the 1977 amendments. These CTGs provided States with information on controls for a number of categories of sources emitting VOCs, and recommended a ''presumptive norm'' for State RACT determinations based on the control levels achievable by sources in a given industry. CTGs reduced the burden on States by eliminating the need for each State to develop its own technical support for implementing the RACT requirement. Since the CTG-recommended controls were based on general capabilities of an industry, EPA in the 1979 guidance (44 FR 53782) urged States in setting RACT to judge the feasibility of the recommended controls on particular sources, and to adjust accordingly.

As noted above, EPA's early guidance related to the RACT requirement indicated that our overriding concern in approving State RACT requirements was attaining the particular NAAQS. We initially required States to apply RACT to qualify for attainment extensions, and in some cases, for plans that could not demonstrate attainment.

During the 1980s, EPA implemented the RACT requirements with a number of CTGs and guidance documents. These materials were aimed at addressing the attainment deadlines of 1982 and 1987 under the 1977 Clean Air Act amendments. During this time, EPA, for pollutants other than ozone, considered RACT to be dependent upon reductions needed for attainment as expeditiously as practicable. For ozone, where the State performed photochemical grid modeling, the approach was the same, but where the State used less sophisticated tools, we considered RACT to be independent of whether the controls were needed to reach attainment as expeditiously as practicable. We took this alternate approach because of concerns related to the precision of modeling techniques. In other words, in those cases, we required that a stationary source of the requisite type and size be subject to RACT, whether or not such controls were actually demonstrated to be necessary for the area to attain by its specified date. (44 FR 20375–20376, April 4, 1979)

Congress followed a similar approach in the 1990 amendments to the CAA for purposes of the ozone NAAQS in the subpart 2 provisions added at that time. For example, section 182(b)(2) requires the imposition of RACT controls for all VOC source categories covered by a CTG and for all other major stationary sources of VOC located within certain nonattainment areas. Thus, Congress required these controls without allowing for an area-specific demonstration by the State that the area needed the controls for attainment as expeditiously as practicable. Extensive discussion of this requirement appeared in the 1992 general preamble (57 FR 13541), in which EPA provided guidance for implementation of the ozone NAAQS.

Notably, Congress did not significantly amend the generally applicable provisions for nonattainment areas that appear in subpart 1 of Part D in 1990. This indicates that Congress intended that the Agency retain the authority to interpret the generally applicable nonattainment area plan requirements of section 172(c), including the RACT and RACM requirements, in the way that is most appropriate for new NAAQS that are subject to subpart 1. As discussed below, EPA has determined that an approach to the RACT requirement in which RACT varies in different nonattainment areas based on the reductions needed for attainment as expeditiously as practicable, is appropriate for implementation of the $PM_{2.5}$ NAAQS. We believe that the improved ability to model air quality impacts of emissions controls allows for this approach.

b. Proposed Options for RACT

The EPA proposed and requested comment on three alternative approaches for interpretation of the RACT requirement of section 172(c)(1) for implementation of the $PM_{2.5}$ NAAQS. The EPA proposed these approaches in order to evaluate which method would best ensure that States consider and adopt RACT measures for stationary sources in a way that is consistent with the overarching requirement to attain the standards as expeditiously as practicable, while providing flexibility for States to focus regulatory resources on those sources of emissions that contribute most to local $PM_{2.5}$ nonattainment.

Under the first proposed alternative, EPA would require States to conduct a RACT analysis and to identify and require reasonably available controls for all affected stationary sources in the nonattainment area, comparable to the implementation of RACT provided in subpart 2 governing implementation of the 1-hour ozone NAAQS. Under this option, covered sources would be required to apply reasonable available controls considering technical and economic feasibility, and there would be no opportunity for States to excuse stationary sources from control on the basis that the emissions reductions from those controls would not be necessary to meet RFP requirements or to reach attainment. Under this alternative, EPA proposed to limit the universe of sources for which States must conduct a RACT analysis and impose RACT controls, by providing an applicability threshold based upon the amount of emissions potentially emitted by the sources. Under this first option, EPA requested comment on a number of alternative emissions applicability thresholds.

Under the second proposed alternative, EPA would require States to conduct a RACT analysis and to identify reasonably available controls for all affected stationary sources. Under this option, however, States could thereafter determine that RACT does not include controls that would not otherwise be necessary to meet RFP requirements or to attain the $PM_{2.5}$ NAAQS as expeditiously as practicable.[23] Under this approach, RACT would be determined as part of the broader RACM analysis and identification of all measures—for stationary, mobile, and area sources—that are technically and economically feasible, and that would collectively contribute to advancing the attainment date.[24] Because RACT and RACM are considered together under this alternative, we did not propose emissions threshold options for evaluation of stationary source RACT. In addition, consistent with existing policies, States would be required to evaluate the combined effect of reasonably available measures to determine whether application of such measures could advance the attainment date by at least one year.[25]

The third proposed alternative, EPA's preferred option in the proposal, combined the first two options and is similar to the RACT approach adopted in the final implementation rule for the 8-hour ozone program. Under the third option, EPA would require States to conduct a RACT analysis and to require reasonably available controls for all affected stationary sources in

[23] Under the Tribal Air Rule (TAR), requirements for RACT and RACM may be considered to be severable elements of implementation plan requirements for Tribes.

[24] In *Sierra Club* v. *EPA*, 294 F.3d 155 (D.C. Cir. 2002), the court stated in upholding EPA's statutory interpretation of RACM that the Act does not compel a state to consider a measure without regard to whether it would expedite attainment.

[25] In this notice, where we use the shorthand phrase ''advance the attainment date,'' it means ''advance the attainment date by one year or more.''

nonattainment areas with attainment dates more than 5 years from the date of designation. For areas with an attainment date within 5 years of designation (e.g. by April 5, 2010 for areas with an effective date for designation of April 5, 2005), EPA would require RACT as under the second proposed alternative, in which RACT would be determined as part of the broader RACM analysis. For these areas, States could determine that RACT does not include controls that would not otherwise be necessary to meet RFP requirements or to attain the $PM_{2.5}$ NAAQS as expeditiously as practicable. The same proposed suboptions with respect to the size of sources for consideration under the first alternative were also included under this alternative.

c. Proposed Approach for RACM

The EPA proposed and asked for comment on one approach for interpreting the RACM requirement for $PM_{2.5}$. The EPA based the proposal on the approach that we adopted for other NAAQS implementation programs. Under this approach, a State provides a demonstration in its SIP that it adopted all reasonably available measures needed to meet RFP requirements and to attain the standard as expeditiously as practicable and that no reasonably available additional measures would advance the advance the attainment date by at least 1 year or would be necessary to meet the RFP requirement for the area.[26]

Under section 172(a)(2), the state implementation plan must provide for a nonattainment area to attain as expeditiously as practicable, but no later than 5 years after the effective date of designation of the area (e.g., no later than April 2010 for the final designations effective April 2005). The statute thus creates a presumption for attainment within 5 years of designation unless certain statutory criteria are met for an extension of the attainment date. Under the proposed approach to RACM for $PM_{2.5}$, each State would evaluate available measures for sources of $PM_{2.5}$ or its regulatory precursors in the area to determine if reasonable measures were needed to meet the RFP requirement or to achieve attainment as expeditiously as practicable. If modeling of all RACM and other state, regional and federal measures indicates that the State will not be able to demonstrate attainment within 5 years after designation based upon the severity of nonattainment in that area or the availability or feasibility of implementing controls in that area, then the State may request an attainment date extension. We proposed that under these circumstances, the EPA could extend the attainment date for a period of 1 to 5 years, when the State shows that it will implement all RACT and RACM as expeditiously as practicable, has met its obligation to address intrastate pollution transport from sources within its jurisdiction, and still needs additional time to attain.

In the proposed rule, the EPA also took comment on the following overall steps for implementing the statutory requirement for RACM.

(1) *Identification of measures.* The State would begin the process of determining RACM by identifying all available control measures for all sources of $PM_{2.5}$ and its precursors in the nonattainment area. The RACM can apply to mobile sources, area sources, and stationary sources.

(2) *Evaluation of measures.* After the State identifies the universe of available measures for the sources in the area, the State would evaluate them to determine whether implementation of such measures is technically and economically feasible, and whether the measure will contribute to advancing the attainment date.

(3) *Adoption of measures.* The State would adopt all reasonably available measures for the area consistent with meeting the applicable RFP requirements and attaining the NAAQS as expeditiously as practicable, in accordance with applicable policy and guidance for attainment demonstrations. We would then approve or disapprove the State's plan through notice and comment rulemaking. We also noted that in reviewing the State's selection of measures for RACM, or determining that certain measures are not RACM, EPA may independently supplement the rationale of the State or provide an alternative reason for reaching the same conclusion as the State.

c. Final Rule

The EPA carefully considered our interpretation of section 172(c)(1) for the $PM_{2.5}$ NAAQS. Because of the variable nature of the $PM_{2.5}$ problem in different nonattainment areas, which may require States to develop attainment plans that address widely disparate circumstances (e.g., different source types and mixes, different precursors and mixes of precursors, and different meteorological conditions), we determined that the regulations implementing the $PM_{2.5}$ NAAQS should provide for a great degree of flexibility with respect to the RACT and RACM controls.

Selected approach to RACT and RACM. The final rule reflects EPA's decision to select option 2 for RACT and to require a combined approach to RACT and RACM. Under this approach, RACT and RACM are those measures that a State finds are both reasonably available and contribute to attainment as expeditiously as practical in the specific nonattainment area.

By definition, measures that are not necessary either to meet the RFP requirement, or to help the area attain the NAAQS as expeditiously as practicable, are not required RACT or RACM for such area. The EPA believes that this approach provides the greatest flexibility to a State to tailor its SIP control strategy to the needs of a particular $PM_{2.5}$ nonattainment area, but it may require the State to conduct a more detailed analysis to identify the most effective RACT/RACM strategy to attain the NAAQS.

During the comment period, commenters raised concerns that this approach may be overly burdensome on States because of the number of potential control measures a State would need to consider. Today, we clarify that although the State must conduct a thorough analysis of reasonably available measures, States need not analyze every conceivable measure, as explained in the guidance below. Instead, ''reason'' should drive States identification of potential measures, but States should remain mindful of the public health risks of $PM_{2.5}$. As long as a State's analysis is sufficiently robust in considering potential measures to ensure selection of all appropriate RACT and RACM, and the State provides a reasoned justification for its analytical approach, we will consider approving that State's RACT/RACM strategy.

Guidance on State analysis to identify RACT, RACM and appropriate attainment date. A State must consider RACT and RACM for all of its nonattainment areas. However, EPA believes that if the State projects that an area will attain the standard within 5 years of designation as a result of existing national measures (i.e. projected to have a design value of 14.5 or lower), then the State may conduct a limited RACT and RACM analysis that does not involve additional air quality modeling. A limited analysis of this type would involve the review of reasonably available measures, the estimation of potential emissions

[26] In the context of the PM_{10} NAAQS, EPA has concluded that ''advancement of the attainment date'' should mean an advancement of at least one calendar year. *See* State Implementation Plans; General Preamble for the Implementation of Title I of the CAA Amendments of 1990, 57 FR 12498 (April 16, 1992). *See also Sierra Club* v. *EPA,* 294 F.3d 155 (D.C. Cir. 2002).

reductions, and the evaluation of the time needed to implement these measures. If the State could not achieve significant emissions reductions during 2008 due to time needed to implement the potential measures or other relevant factors, then the State and EPA could conclude that there are no further reasonably available control measures for that area that would advance the attainment date by one year or more relative to the presumptive outer limit for attainment dates, i.e., 5 years from designation. In lieu of conducting air quality modeling to assess the impact of potential RACT and RACM measures, States may consider existing modeling information to determine the magnitude of emissions reductions that could significantly affect air quality and potentially result in attaining prior to 2010 (e.g. in 2009 based on 2006–8 air quality data). If the State, in consultation with EPA, determines from this initial, limited RACT and RACM analysis that the area may be able to advance its attainment date through implementation of reasonable measures, then the State would conduct a more detailed RACT and RACM analysis, including appropriate air quality modeling analyses, to assess whether it can advance the attainment date.

In general, the combined approach to RACT and RACM in the final rule includes the following steps: (1) Identification of potential measures that are reasonable; (2) modeling to identify the attainment date that is as expeditious as practicable; and (3) selection of RACT and RACM.

Identification of potential measures. The State's review of potential measures must be sufficient to identify all appropriate RACT and RACM. As stated previously, inherent to RACT/RACM is the basic requirement that the measure be ''reasonable.'' A State need not evaluate measures in its RACM/RACT analysis that it determines are unreasonable such as measures that are ''absurd, unenforceable, or impractical'' or that would cause ''severely disruptive socioeconomic impacts, (e.g. gas rationing and mandatory source shutdowns); such measures are not required by the Act. 55 FR 38327.

As we also stated earlier, a State's RACT/RACM analysis not only involves an assessment about what emissions sources to control and to what level, but also a judgment as to when it is reasonable to require a sector to comply with a given measure. Accordingly, if the State or Federal rules already heavily regulate a given sector, it is reasonable for the State to first look to unregulated parts of the sector for RACT/RACM measures, especially, in light of costs already realized by the regulated sector. A State may conclude that it is unreasonable to further regulate the industry, or that it is only reasonable to impose measures in the latter years of the attainment plan.

Finally, the State should use reason in the extent of its efforts to identify potential control measures. For example, if a review of monitoring data and modeling studies indicates that reductions in SO_2 are much more effective in reducing ambient $PM_{2.5}$ than reductions in other pollutants, we expect that the State will more vigorously identify RACT/RACM measures for SO_2 than for other pollutants. Conversely, if reductions in a given pollutant, even in large quantities, would have trivial impacts on $PM_{2.5}$, less rigor is needed in the State's assessment of controls for that pollutant, because such controls could not contribute to advancing the attainment date. Likewise, where reducing emissions of a pollutant is effective in reducing ambient $PM_{2.5}$, if the emissions inventory for that pollutant is dominated by a given type of emissions source, then it would be appropriate to focus the analysis on measures for that segment of the inventory. No RACT/RACM analysis is needed for pollutants that are not attainment plan precursors for a particular $PM_{2.5}$ nonattainment area.

As supporting information for identification of RACT and RACM, the State ordinarily provides data on technologically feasible control measures:

—A list of all emissions source categories, sources and activities in the nonattainment area (for multi-State nonattainment areas, this would include source categories, sources and activities from all states which make up the area)

—For each source category, source, or activity, an inventory of direct $PM_{2.5}$ and precursor emissions;

—For each source category, source, or activity, a list of technologically feasible emission control technologies and/or measures [27]

—For each technologically feasible emission control technology or measure, the State should provide the following information: (1) The control efficiency by pollutant; (2) the possible emission reductions by pollutant; (3) the estimated cost per ton of pollutant reduced; and (4) the date by which the technology or measure could be reasonably implemented.

Based on this and other relevant information, the State will identify the reasonable measures (potential RACT and RACM) to be included in air quality modeling. (At its option, the State may prefer not to make a judgment on whether certain measures are technically and economically feasible, if it believes they will not contribute to earlier attainment. In that case, the State could include those measures in the modeling, and later exclude them from RACT and RACM by showing that all the excluded measures together would not advance the attainment date by at least 1 year.) As previously mentioned, in determining the attainment date that is as expeditious as practicable, the State should consider impacts on the nonattainment area of intrastate transport of pollution from sources within its jurisdiction, and potential reasonable measures to reduce emissions from those sources.

Modeling to determine the attainment date that is as expeditious as practicable. Second, for purposes of determining the attainment date that is as expeditious as practicable, the State will need to conduct modeling to show the combined air quality impact of all of the potential measures identified in the first step with a modeling analysis for the year 2009. A base case scenario for the year 2009 would project future air quality given implementation of existing measures (Federal, State and local). If this base case scenario demonstrates attainment by 2010, then the State must demonstrate why attainment could not be achieved in an earlier year. (As noted above, given the April 2008 due date for SIP submissions, it may be difficult to achieve earlier attainment in many cases).

If the base case scenario does not demonstrate attainment, then a control case scenario (described below) is needed to examine whether the reasonable, technically and economically feasible measures identified by the State would result in attainment in 2009. The control case scenario would add potential SIP measures—e.g. potential RACT/RACM, plus any candidate intrastate transport measures that the State has identified

[27] The EPA believes that it is not necessary to identify every possible variation of every type of control measure, or all possible combinations of technologies and measures that would apply to a given source or activity if the State has properly characterized the potentially available emissions reductions and their costs. For example, EPA believes that the State can conduct a thorough analysis of VMT reduction measures without including every possible level or stringency of implementation of certain possible measures or combinations of measures for reducing VMT, so long as those measures would not affect the overall assessment of VMT reduction capabilities and the associated costs.

and would be feasible to implement by that year. States in multi-State nonattainment areas are strongly encouraged to collaborate on their modeling analyses. This modeling, along with other information known as weight of evidence considerations, would inform a judgment as to whether reasonable measures could lead to attainment of the standards within 5 years after designation. If the analysis does not demonstrate attainment by April 2010 (2009 analysis year), then the analysis would serve as the technical basis for the State to seek an extension of the attainment date for that area. Further analysis would then be necessary and is required to identify the specific attainment date.

The choice of future years to model beyond 2010 may vary from area to area. Often, modeling potential controls in two different future years may be necessary to support a judgment that a projected attainment year is as expeditious as practicable. If the area is projected to remain over the standard in the early projection year (e.g., 2009) despite the emission reductions from the modeled control measures, but is projected to be well below the standard in the later projection year (e.g., 2012), interpolation and emission inventory analysis could identify an intermediate year as the appropriate attainment date. There may be cases in which modeling a single year is sufficient because modeling of all technically and economically feasible controls results in attainment by a narrow margin in that year.

For many areas, EPA modeling analysis for CAIR and other modeling analyses that have been performed suggest a number of nonattainment areas will have a modest amount (in some cases only a few tenths of a microgram) of needed reductions in ambient levels after 2010 to reach attainment. For any such area, and for areas otherwise expected to attain relatively soon after 2010 (for example, due to substantial reductions in a dominant local source), EPA believes that this analysis should be for a year no later than 2012. A later date (e.g., 2014) may be appropriate for areas with very high $PM_{2.5}$ levels that face difficulty attaining within 10 years.

The EPA believes that it is not reasonable to require States to model each and every year between 2009 and 2014 to determine the appropriate attainment date. Modeling future year inventories is a time consuming and resource intensive process. Multiple models and pre-processors are needed in order to generate year specific emissions for the various emissions sectors (e.g. mobile, non-road, non-EGU point, EGU point, etc.). Because it is not reasonable to model every year, a logical choice often may be to model a year in the middle of the period. As such, we recommend modeling an emissions year no later than 2012 as the initial extension date (which translates to a 2013 attainment date). If this modeling indicates that the area can reach attainment by 2012, then the State can further analyze emissions and strategies to determine if the attainment date can be advanced to an earlier year. If the modeling indicates that the area cannot reach attainment by 2012, then the modeling will serve as further justification for granting a longer attainment date extension (e.g., attainment date of 2015 with modeling for 2014). In that case, additional modeling of 2014 with further emissions controls would be required in order to show attainment. Again, the State should then further analyze emissions and strategies to determine if the attainment date can be advanced to an earlier year between 2012 and 2015.

Additionally, in the discussion of air quality modeling issues in section II.E above, we discuss the benefits of addressing control strategies for multiple pollutants. Part of the challenge of multi-pollutant modeling is coordinating the future modeling years for different pollutants in order to minimize the number of required future year model runs. As part of the requirements of the 8-hour ozone implementation rule, States are currently working on modeling analyses for 2009 and in some cases for 2012 (serious nonattainment areas). For an area that cannot attain the $PM_{2.5}$ NAAQS by 2010, this may be reason to select 2012 as the year to model, so that the State could conduct the modeling for both ozone and $PM_{2.5}$ in tandem. This would, in some cases, allow the pooling of resources (e.g., inventories, model runs, etc.) and provide for faster development of a $PM_{2.5}$ attainment demonstration.

It may also be possible for the State to look at 2009 and 2014 only. In this instance, the State may find sufficient data to interpolate results for the years in between based on estimated changes in emissions.

We emphasize that when a State models later years, that this analysis must take into account potential controls that the State may have determined would not be RACT or RACM for an earlier year. For example, some measures that are impractical to implement by 2009 could be reasonable if implemented by 2010, 2011 or 2012. Thus, when the State models later years, the list of potential controls should be expanded to include technically and economically feasible measures that can be implemented by the analysis year.

Selection of RACT & RACM. Based on this analysis, the State should make decisions on RACT, RACM, intrastate measures, and the attainment date that is as expeditious as practicable. Because EPA is defining RACT and RACM as only those reasonable, technically and economically feasible measures that are necessary for attainment as expeditiously as practicable, the State need not adopt all feasible, reasonable measures. The State may exclude those reasonable measures that, considered collectively, would not advance the attainment date.

Comments and Responses

Comment: A number of commenters generally supported EPA's second proposed alternative to RACT (option 2). Most of these commenters expressed concern that the other options would require the imposition of controls whether or not they were needed to attain the $PM_{2.5}$ standards as expeditiously as practicable. Some State and local commenters also urged EPA to select option 2 as the best interpretation of the RACT requirement for $PM_{2.5}$ because they believe that it will be the most appropriate approach for designing attainment strategies for their particular nonattainment area or areas.

Response: The EPA agrees that these two points are important considerations. After carefully considering the options, we concluded that Option 2 was the most suitable approach for the $PM_{2.5}$ NAAQS. Options 1 and 3 do not reduce the States' burden to analyze potential control measures as the States would still be required to look beyond the mandated RACT for reasonably available control measures (RACM). Moreover, Options 1 and 3 could require imposition of controls on some sources that would not strictly be necessary to attain the NAAQS as expeditiously as practicable. Given the nature of the $PM_{2.5}$ nonattainment problem, EPA concluded that an interpretation that provides the maximum flexibility is a better approach.

Comment: Some commenters recommended that EPA modify proposed option 2 to include a tons-per-year threshold. Under such an approach, the States and EPA would only require RACT for sources whose emissions were above the threshold. Most of these comments recommended a RACT threshold of 100 tons per year. These commenters expressed concern that if option 2 were implemented

without such a threshold, States would be burdened with conducting RACT analyses for very small sources or source categories with low emissions.

Response: The EPA believes that under the approach chosen for the final rule in which RACT is considered to be a part of the overall RACM process, it would be difficult to define a threshold that would apply for all types of sources and for all types of control measures in all nonattainment areas. It has not been common practice under past EPA policy to establish or use an emissions threshold when considering sources for possible emission reductions as part of a RACM analysis to show attainment as expeditiously as practicable. Indeed, many of the control technique guidelines for VOC RACT do not recommend an emissions threshold. A state needing significant emission reductions to attain the standards in a given area even by 2015 would likely conclude that controls should be considered on smaller sources. In contrast, a State with an area that exceeds the standard by only a few tenths of a microgram per cubic meter may not need to consider controls on smaller source to reach attainment as expeditiously as practicable. The EPA has selected option 2 for interpretation of the RACT requirement for $PM_{2.5}$, in part, specifically because that approach contemplates that States will conduct an appropriate analysis of the spectrum of source categories and potential controls available. To cut off such analysis at a set emissions-based cut point for all sources and all areas would undermine one of the key benefits of the approach. Accordingly, EPA disagrees with comments that option 2 should include a nationally-defined threshold for the size of sources or source categories that require RACT analyses.

Comment: A number of commenters supported EPA's first and third proposed alternative approaches to RACT (option 1 and option 3). Commenters supporting these two options used similar reasoning. Commenters cited the statutory language in section 172(c)(1) requiring that the attainment plan provide for ''at a minimum'' the adoption of RACT. Accordingly, these commenters argued that RACT is an independent, minimum requirement of attainment plans irrespective of the attainment demonstration and that option 2, which would not require the adoption of RACT for all sources, has no policy or legal justification. Other commenters noted that option 1 would be much easier to implement, because RACT would be defined according to technical reasonableness and would not hinge on complicated determinations involving attainment demonstrations. Some commenters argued that option 1 provides for greater equity, because similar measures would be required for similar sources for all nonattainment areas. Finally, some commenters believed that it is inherently inconsistent to assert that plans have met the requirement for attainment ''as expeditiously as practicable'' without applying RACT to all major sources.

Response: The EPA disagrees with these comments. The EPA believes that option 2 is fully consistent with section 172(c)(1). Section 172(c)(1) requires that attainment plans must provide for the implementation of RACM as expeditiously as practicable (including such reductions in emissions from existing sources in the area as may be obtained through the adoption, at a minimum, of RACT). Contrary to the commenters' assertions, this language does not demonstrate that RACT is required for all sources, independent of RACM and attainment demonstrations. Moreover, this provision does not require RACT whether or not imposition of technology would advance the attainment date. Instead, section 172(c)(1) explicitly provides that RACT is included within the definition of RACM, and EPA has previously determined that the CAA only requires such RACM as will provide for attainment as expeditiously as practicable. (See 57 FR 13498, 13560). The courts have deferred to this interpretation and concluded that EPA interprets RACM as a collection of reasonable measures that would advance the attainment date. See *Sierra Club* v. *EPA*, 294 F.3d 155, 162 (D.C. Cir. 2002); see also *Sierra Club* v. *EPA*, 314 F.3d 735, 744 (5th Cir. 2002). The CAA does not ''compel [ ] a State to consider whether any measure is 'reasonably available' without regard to whether it would expedite attainment in the relevant area.'' *Sierra Club* v. *EPA*, 294 F.3d at 162. The EPA concludes that because section 172(c)(1) establishes that RACT is a part of RACM, EPA is reasonably applying the same interpretation to the RACT requirement for $PM_{2.5}$. The RACT is a part of the collection of measures that are necessary to reach attainment as expeditiously as practicable. It is thus directly related to what a specific area needs to attain the NAAQS, and States need not implement reasonably available measures that would not advance the attainment date as part of the $PM_{2.5}$ RACT requirement.

The EPA also finds that option 2 is consistent with the statutory language providing that a State must apply RACT to existing sources, ''at a minimum,'' to meet its requirement to apply RACM. We interpret the ''at a minimum'' clause to mean that when a State determines that control of a specified existing stationary source(s) is necessary to attain, the State must apply RACT to that source. Further, EPA believes this requirement for RACT applies to stationary sources as a group, and not to each stationary source.

The EPA finds sound policy reasons for choosing option 2. While an approach that provided for application of the same controls in all areas would provide for more equity across areas, EPA emphasizes that equity is only one of many factors considered by EPA when deciding between options 1, 2 and 3. The EPA believes that it is also important to ensure that control strategies focus on the most effective measures with the greatest possibility for significant air quality improvements. In addition, while EPA agrees that options 1 and 3 could provide for greater ease of implementation, this is also only one of the factors EPA considered when deciding between the proposed options. Under option 2, States have a greater burden and responsibility to identify the local strategy that is tailored to their particular air quality problem. At the same time, the States have the ability to identify the sources with the greatest impact on nonattainment and to identify a sound strategy that achieves attainment in the most sensible manner. The EPA believes that approaching RACT and RACM in this manner is consistent with the overall philosophy imbedded in the SIP program since its inception in the late 1960s and early 1970s.

Comment: Some commenters believed that the proposed RACM requirement was too broad. These commenters believed that the requirement to analyze the entire ''universe'' of possible measures was too burdensome for States. Commenters felt this was especially true in light of the lack of federally issued CTG and ACT documents for $PM_{2.5}$ and its precursors for all potential source categories.

Response: As explained earlier, States should apply ''reason'' in identifying measures to evaluate as potential RACM/RACT. We recognize that States are implementing the $PM_{2.5}$ standard for the first time, and do not have the long history and experience in implementing $PM_{2.5}$ as they have in implementing the PM_{10} and ozone standards. Accordingly, we expect that both the States and EPA will expend extra effort in developing and evaluating attainment plans that contain appropriate controls. A number

of resources exist to provide States with information on potential control measure costs and emissions reductions. We intend to facilitate the sharing of information through a control measure website and other efforts, and expect that States will develop screening methods to reduce the burden of analysis.

Comment: One commenter asserted that EPA should not require the analysis for, or implementation of, RACT and RACM for sources throughout the entire nonattainment area, and should permit States to focus only on sources located in smaller specific ''problem areas'' within the nonattainment area.

Response: The EPA designated areas nonattainment based upon analysis of the geographic area with sources that ''contribute'' to the violation of the NAAQS in the area, in accordance with section 107(d). These designations are based upon, among other things, a network of monitors that the State and EPA previously agreed represented the ambient air concentrations throughout the area. Additional analysis of information during the designation process indicated those areas that contributed to the violations at the violating monitor because of, among other things, the amount of emissions in such adjoining areas. Accordingly, the State in which a nonattainment area is located must evaluate the full range of sources of $PM_{2.5}$ and its precursors throughout the designated nonattainment area during the development of the SIP. The EPA agrees that there are some nonattainment areas where one or a few large emissions sources may be causing localized concentrations at a monitor that are much higher than those within the remainder of the nonattainment area. For such areas, the nonattainment strategy will likely not succeed without addressing those sources. The EPA does not, however, believe it is acceptable that the nonattainment strategy focus only on those sources, because additional reductions within the nonattainment area would still have the potential to advance the attainment date. Exempting portions of the nonattainment area could expose a portion of the public residing downwind in the area to exposure to levels of $PM_{2.5}$ that exceed the NAAQS for longer than necessary, and the health detriments from such exposure, merely to minimize the impact of having to impose control strategies on sources upwind. Moreover, to the extent that monitoring in one portion of a nonattainment area indicates violations in multiple portions of the area, a strategy that solely focused upon the sources in the immediate vicinity of the monitor might fail to assure that the NAAQS is achieved throughout the area. Because NAAQS violations generally reflect a combination of regional scale, metropolitan scale, and local scale impacts, and all three scales must be addressed, EPA requires RACT/RACM submittals to address sources throughout the nonattainment area.

Comment: Some commenters agreed with EPA's view that State's RACM analysis must address those measures that a State declines to adopt and must show whether the combined measures would cumulatively advance the attainment date by at least 1 year. One commenter questioned the legal basis for EPA's determination that the only controls necessary to attain the $PM_{2.5}$ NAAQS as expeditiously as practicable are those that would cumulatively advance an area's projected attainment date by at least one calendar year. The commenter suggested that control measures that would advance attainment by a smaller increment ''would meet the criteria endorsed in Sierra Club [Sierra Club v. EPA, 294 F.3d 155 (D.C. Cir 2002)] by 'expedit[ing] attainment in the relevant area.' ''

Response: The EPA has consistently interpreted RACM as a collection of measures that would advance the attainment date by at least 1 year, and the courts have determined that the statutory RACM requirement is ambiguous and deferred to EPA's interpretation of the requirement. See *Sierra Club* v. *EPA*, 314 F.3d 735, 744 (5th Cir. 2002); see also *Sierra Club* v. *EPA*, 294 F.3d, 155 162 (D.C. Cir. 2002). Contrary to the commenter's suggestion, the court in *Sierra Club* v. *EPA*, did not endorse specific criteria for identifying control measures that expedite attainment, but instead deferred to EPA's interpretation of an ambiguous statutory term. The courts deferred to EPA's interpretation after reviewing EPA's approval of State SIP submissions. The EPA conducts such reviews consistent with its determination that the CAA only requires such RACM as will provide for attainment as expeditiously as practicable, and its belief that it would be unreasonable to require implementation of measures that would not in fact advance attainment. See 57 FR 13498, 13560 (April 15, 1992); see also 44 FR 20372, 20374 (April 4, 1979). In considering whether a collection of measures would advance the attainment date of an area, EPA has previously interpreted the phrase ''advance the attainment date'' as meaning that the attainment date would be advanced by at least 1 year. See e.g., 66 FR 57160, 57182 (Nov. 14, 2001) (approval of Houston SIP); 66 FR 586 (Jan 3. 2001) (approval of DC area SIP). Further, EPA's use of a one-year increment in determining whether a collection of measures would advance the attainment date is reasonable and consistent with the fact that all areas will be designing attainment demonstrations for the annual $PM_{2.5}$ standard. Section 172(a)(2)(C) statute uses 1 year as the increment by which attainment date extensions can be granted. Thus, requiring evaluation of whether control measures would advance attainment by an increment of 1 year is a reasonable approach for the $PM_{2.5}$ NAAQS.

Comment: Some commenters recommended that EPA consider not requiring a RACM analysis for areas projected to attain the standards within 5 years of designation, i.e., by April 2010 for the areas currently designated nonattainment. One commenter suggested that practical considerations would make it impossible for any State projected to attain by 2010 to advance the attainment date by a year. This commenter noted that because measures to provide for attainment by 2010 must be implemented by the beginning of 2009, and SIPs are not submitted until April 2008, it would impossible to advance the implementation of measures by 1 year (that is, the beginning of 2008).

Response: The EPA generally agrees that given the time constraints it will be difficult for States with areas currently designated nonattainment to devise, adopt, and implement RACM measures to advance the attainment date before 2010. At the same time, however, we note that nothing precludes States from taking early action and we encourage States to take actions to reduce $PM_{2.5}$ concentrations where feasible even before the SIPs are submitted. RACM is required by the CAA and thus EPA cannot waive the requirement for the analysis. At the same time, EPA recognizes that a streamlined analysis may be appropriate given the short time periods involved.

3. Observations and Considerations in Determining RACT and RACM

a. Background

The preamble to the proposed rule included a discussion of general considerations for RACT (70 FR 66020 and 66021, latter part of section III.I.6) and RACM (70 FR 66028, section III.1.15). The preamble to the final rule retains this discussion with some modifications and restructuring to

reflect the combined approach to RACT and RACM

b. Final Rule

General considerations. Once the State has identified measures and technologies that are available for implementation in the nonattainment area, then it must evaluate those measures to determine whether implementation of such measures are reasonable, and would collectively advance attainment. Many of the factors that the State should take into consideration in determining whether a measure is ''reasonable'' are related to the measure's technical and economic feasibility. Since RACM applies to area and mobile sources as well as stationary sources, the State should consider other factors as well in conducting its RACM analysis. For example, in many cases obtaining emissions reductions from area and mobile sources is achieved not by adding control technology to a specific emissions source, but by reducing the level of activity of a fleet of vehicles or by modifying a type of commercial process. In these situations, the State should also consider local circumstances such as infrastructure, population, or workforce and the time needed to implement the measure in light of the attainment date.

The EPA believes that while areas projected to attain within 5 years of designation as a result of existing national measures should still be required to conduct a RACT and RACM analysis, such areas may be able to conduct a limited RACT and RACM analysis that does not involve additional air quality modeling. A limited analysis of this type could involve the review of available reasonable measures, the estimation of potential emissions reductions, and the evaluation of the time needed to implement these measures. If the State could not achieve significant emissions reductions by the beginning of 2008 due to time needed to implement reasonable measures or other factors, then it could be concluded that reasonably available local measures would not advance the attainment date. In lieu of conducting air quality modeling to assess the impact of potential RACT and RACM measures, existing modeling information could be considered in determining the magnitude of emissions reductions that could significantly affect air quality and potentially result in earlier attainment. If the State, in consultation with EPA, determines from this initial, more limited RACT and RACM analysis that the area may be able to advance its attainment date through implementation of reasonable measures, then the State would conduct a more detailed RACT and RACM analysis.

Observations on control opportunities. The implementation of the $PM_{2.5}$ NAAQS is in its initial stages, and many of the designated $PM_{2.5}$ nonattainment areas are not current or former PM_{10} nonattainment areas. Thus, some existing stationary sources in these areas may currently be uncontrolled or undercontrolled for $PM_{2.5}$ or $PM_{2.5}$ precursors. Further, to this point in time, emissions controls for existing sources in these areas may have focused primarily on particulate matter that is filterable at stack temperatures and thus may not adequately control condensable emissions. In addition, States should bear in mind that the controlled sources may have installed emission controls 15 years ago or more, and there may now be cost-effective opportunities available to reduce emissions further through more comprehensive and improved emissions control technologies, or through production process changes that are inherently lower in emissions.

Moreover, improved monitoring methods may enhance the ability of sources to maintain the effectiveness of installed emissions controls and to reduce emissions by detecting equipment failures more quickly. For example, State imposition of requirements for more frequent monitoring (e.g., continuous opacity monitors, PM continuous emissions monitors, etc.) may provide greater assurance of source compliance and quicker correction of inadvertent upset emissions conditions than existing approaches.

Even in former or current PM_{10} nonattainment areas, existing requirements for controlling direct PM emissions (e.g., with a baghouse or electrostatic precipitator) may not have been revised significantly since the 1970's. When EPA established the PM_{10} standards in 1987, we stated in the preamble that it was reasonable to assume that control technology that represented RACT and RACM for total suspended particulates (TSP) should satisfy the requirement for RACT and RACM for PM_{10}. 52 FR 24672 (July 1, 1987). The basis for EPA's belief was that controls for PM_{10} and TSP would both focus on reducing coarse particulate matter, and specifically that fraction of particulate matter that is solid (rather than gaseous or condensable) at typical stack temperatures. However, emission controls to capture coarse particles in some cases may be less effective in controlling $PM_{2.5}$. For this reason, there may be significant opportunities for sources to upgrade existing control technologies [28] and compliance monitoring methods to address direct PM emissions contributing to fine particulate matter levels with technologies that have advanced significantly over the past 15 years.

Precursor Controls. It will be important for States to conduct RACT and RACM determinations for stationary sources of $PM_{2.5}$ precursors as well as direct $PM_{2.5}$ emissions although, as noted above, the known atmospheric chemistry of the area may dictate the necessary rigor of this analysis. A significant fraction of $PM_{2.5}$ mass in most areas violating the standards is attributed to secondarily-formed components such as sulfate, nitrate, and some organic PM, and EPA believes that certain stationary sources of precursors of these components in nonattainment areas currently may be poorly controlled. Accordingly, to address these precursors, States should review existing sources for emission controls or process changes that could be reasonably implemented to reduce emissions from activities such as fuel combustion, industrial processes, and solvent usage.

Multi-State Nonattainment Areas. States in multi-State nonattainment areas will need to consult with each other on appropriate level of RACT and RACM for that area. We anticipate that States may decide upon RACT and RACM controls that differ from State to State, based upon the State's determination of the most effective strategies given the relevant mixture of sources and potential controls in the relevant nonattainment areas. So long as each State can adequately demonstrate that its chosen RACT and RACM approach will provide for meeting RFP requirements and for attainment of the NAAQS as expeditiously as practicable for the nonattainment area at issue, we anticipate approving plans that may elect to control a somewhat different mix of sources or to implement somewhat different controls as RACT and RACM. Nevertheless, States should consider RACT and RACM measures developed for other areas or other States. EPA may consider such measures in assessing the approvability of a State's SIP.

c. Comments and Responses

Comment: In the proposed rule, EPA indicated that States could consider the ''social acceptability'' of measures as a

[28] For example, see past EPA guidance on $PM_{2.5}$ control technologies: Stationary Source Control Techniques Document for Fine Particulate Matter (EPA–452/R–97–001), EPA Office of Air Quality Planning and Standards, October 1998.

factor in the determination of what constitutes RACM in a given area. A number of commenters recommended that EPA eliminate use of this factor. Some commenters questioned whether States or EPA had the legal authority to exclude measures from consideration based on social acceptability or popularity, if the measures are technically and economically available, and are needed to attain the NAAQS for protection of public health. Others expressed concerns that inclusion of such a factor would inevitably result in the elimination of controls for area and mobile sources and for this reason would unfairly focus emissions reduction strategies on industrial sources of $PM_{2.5}$ and precursors.

Response: The EPA believes that in developing RACM measures, it is important that States not rely unduly on measures that would be very difficult to enforce in practice. We discourage States from relying on measures that on paper may seem reasonably available but in practice might fail to achieve benefits due to the problems and costs of effectively enforcing these measures. However, we recognize that the CAA does not identify ''social acceptability'' as a factor in the definition of what may constitute RACT or RACM, and more generally the CAA does not establish a preference for measures that affect industrial sources instead of the general public and are therefore more likely to be ''socially acceptable.'' Therefore, given the concerns raised by commenters that establishment of ''social acceptability'' as a factor in the RACM analysis is without basis in the CAA and might result in inappropriate skewing of control strategies, we have removed this term from the final rule. We reiterate, however, that capability of effective implementation and enforcement are relevant considerations in the RACM analysis, even though public ''unpopularity'' is not. Moreover, in assessing the efficacy of measures and the credit they should be given in the context of attainment demonstrations or RFP calculations, EPA believes that such considerations are important.

4. What Factors Should States Consider in Determining Whether an Available Control Technology or Measure Is Technically Feasible?

a. Background

The following provides guidance for States to consider in determining whether an available control technology is technologically feasible.

b. Final Rule

The technological feasibility of applying an emission reduction method to a particular source should consider factors such as the source's process and operating procedures, raw materials, physical plant layout, and any other environmental impacts such as water pollution, waste disposal, and energy requirements. For example, the process, operating procedures, and raw materials used by a source can affect the feasibility of implementing process changes that reduce emissions and the selection of add-on emission control equipment. The operation and longevity of control equipment can be significantly influenced by the raw materials used and the process to which it is applied. The feasibility of modifying processes or applying control equipment also can be influenced by the physical layout of the particular plant. The space available in which to implement such changes may limit the choices and will also affect the costs of control.

Reducing air emissions may not justify adversely affecting other resources by increasing pollution in bodies of water, creating additional solid waste disposal problems or creating excessive energy demands. An otherwise available control technology may not be reasonable if these other environmental impacts cannot reasonably be mitigated. For analytic purposes, a State may consider a $PM_{2.5}$ control measure technologically infeasible if, considering the availability (and cost) of mitigating adverse impacts of that control on other pollution media, the control would not, in the State's reasoned judgment, provide a net benefit to public health and the environment. However, in many past situations, States and owners of existing sources have adopted $PM_{2.5}$ control technologies with known energy penalties and some adverse effects on other media, based on the reasoned judgment that installation of such technology would result in a net benefit to public health and the environment. States should consider this in determining technical feasibility. The costs of preventing adverse water, solid waste and energy impacts should be included in assessing the economic feasibility of the $PM_{2.5}$ control technology.

One particular cross-media issue relates to concentrated animal feeding operations (CAFOs). Should a State determine that reductions of direct $PM_{2.5}$ or $PM_{2.5}$ precursors from CAFOs are necessary for attainment in a nonattainment area, EPA strongly suggests that the State address these reductions from a cross-media perspective. Since 2003, EPA and many stakeholders have been interested in developing a framework to enable CAFOs to pursue superior environmental performance across all media. We are aware that today some CAFOs voluntarily conduct whole-farm audits to evaluate releases of pollutants to all media through Environmental Management Systems, self-assessment tools, performance track, ISO 14001 certification, and State-approved trade offs in meeting regulatory thresholds between air and water that accomplish the best overall level of environmental protection given State and local conditions. The EPA continues to believe the development of new and emerging technologies offers the potential to achieve equivalent or greater pollutant reductions than achieved solely by effluent guidelines and standards. Many of these are superior from a multimedia perspective, and EPA would like to encourage superior multimedia solutions. SIPs which need to address ammonia may provide a unique opportunity to encourage multimedia approaches at CAFOs. For example, the addition of animal by-products provides a valuable source of nutrients for crops, improves soil structure which enhances soil permeability, and adds valuable organic matter that improves soil health. However, inappropriate application can lead to air and water quality concerns or the improvement of one media at the cost of another. Optimal application technologies and rates reduce potential air and water quality standards violations. The EPA does not want to discourage approaches that are superior from a cross media perspective.

The EPA recommends that States evaluate alternative approaches to reducing emissions of particulate matter by reviewing existing EPA guidance [29] and other sources of control technology information. The EPA's 1998 guidance presents information on topics such as the design, operation and maintenance of general particulate matter control systems such as electrostatic precipitators, fabric filters, and wet scrubbers. The filterable particulate matter collection efficiency of each system is discussed as a function of particle size. The guidance document also provides information concerning

[29] Stationary Source Control Techniques Document for Fine Particulate Matter (EPA–452/R–97–001), EPA Office of Air Quality Planning and Standards, October 1998. See also: Controlling SO_2 Emissions: A Review of Technologies (EPA/600/R–00/093), EPA Office of Research and Development, November 2000.

other relevant considerations such as energy and environmental considerations, procedures for estimating costs of particulate matter control equipment, and evaluation of secondary environmental impacts. Because control technologies and monitoring approaches are constantly being improved, the State should also consider more updated or advanced technologies not referenced in this 1998 guidance when conducting a RACT determination. Emissions reductions may also be achieved through the application of monitoring and maintenance programs that use critical process and control parameters to verify that emission controls are operated and maintained so that they more continuously achieve the level of control that they were designed to achieve.[30]

c. Comments and Responses

Comment: One commenter noted that the guidance for ''technical feasibility'' implies that States look at individual sources with a BACT-like case-by-case analysis. The commenter recommended that source owners conduct such a site-specific analysis and submit the analysis to the State through the permitting process.

Response: While the analytical analysis to identify RACT is similar to BACT, as noted above, EPA in the past has issued CTGs that describe the presumptive norm for RACT controls for a given industry, but that allow for case-by-case considerations for a given source. Where States wished to require source owners to conduct such a site-specific analysis as part of the control technology review, EPA supports this type of process. On the other hand, EPA does not believe it would be appropriate to require all RACT-eligible sources to conduct such an analysis, given that States have the primary responsibility for identifying and analyzing measures for such sources.

5. What Factors Should States Consider in Determining Whether an Available Control Technology or Measure Is Economically Feasible?

a. Background

The follow provides guidance for States to consider in determining whether an available control technology is economically feasible for purposes of identifying reasonably available control measures. This guidance is slightly modified from our proposal.

[30] See EPA's Web site for more information: *http://www.epa.gov/ttn/emc/monitor.html.*

b. Final Rule

Economic feasibility encompasses considerations such as whether the cost of a potential measure is reasonable considering attainment needs of the area and the costs of other measures, and whether the cost of a measure is reasonable for the regulated entity to bear, in light of benefits.

While many States generally establish RACT requirements for a category of sources, the Act does not require the same level of control on all sources in a category, nor does the Act require that each source be controlled individually. Similar sources may have different marginal costs, profit margins and abilities to pass costs through to the consumer. These factors are appropriate to consider in determining whether a given level of control is appropriate for an individual source or category of sources. Accordingly, there is no presumption that a given source must bear a cost similar to any other source.

States should consider the capital costs, annualized costs, cost effectiveness of an emissions reduction technology, and effects on the local economy in determining whether a potential control measure is reasonable for an area or State. One available reference for calculating costs is the EPA Air Pollution Control Cost Manual,[31] which describes the procedures EPA uses for determining these costs for stationary sources. The above costs should be determined for all technologically feasible emission reduction options if such measure is inherently ''reasonably available'' (e.g., not absurd or clearly impractical). States may give substantial weight to cost effectiveness in evaluating the economic feasibility of an emission reduction technology. The cost effectiveness of a technology is its annualized cost ($/year) divided by the emissions reduced (i.e., tons/year) which yields a cost per amount of emission reduction ($/ton). Cost effectiveness provides a value for each emission reduction option that is comparable with other options and other facilities. Where multiple control options exist for a given source or source category, States should consider both the cost effectiveness (dollars per ton) of each option, and the incremental cost effectiveness per ton between the options (incremental increase in cost between options divided by the incremental tons reduced).

In determining whether a given measure is reasonable, States may consider costs per ton of other measures previously employed to reduce that pollutant, but similar costs are not conclusive. As discussed above, States may evaluate equity considerations in weighing the economic feasibility of imposing a measure on a given source or source category.

We anticipate that States may decide upon RACT and RACM controls that differ from State to State, based on the State's determination of the most effective strategies given the relevant mixture of sources and potential controls in the relevant nonattainment areas, and differences in the difficulty of reaching attainment.

In considering what level of control is reasonable, EPA is not proposing a fixed dollar per ton cost threshold for RACT, consistent with the views of multiple commenters. Areas with more serious air quality problems typically will need to obtain greater levels of emissions reductions from local sources than areas with less serious problems. Where essential reductions are more difficult to achieve (e.g., because many sources are already controlled), the cost per ton of control may necessarily be higher.

It is not appropriate to assume that the same cost per ton range is reasonable for direct $PM_{2.5}$ and different precursors, because an equal amount of emission reduction in different pollutants has a different impact on $PM_{2.5}$ ambient levels. For example, in a given nonattainment area, reductions of direct $PM_{2.5}$ emissions may prove more expensive than reductions of NO_X emissions, but the resulting benefits of reductions of direct $PM_{2.5}$ might warrant the higher costs. A State should consider this differential impact on ambient $PM_{2.5}$ in considering RACT for controlling different pollutants. During the SIP process, States and regional planning organizations typically conduct sensitivity modeling that can provide this information. Also, the PM NAAQS RIA provides information on the differential impact of $PM_{2.5}$ and PM precursor reductions on ambient $PM_{2.5}$ levels in various areas.[32]

One of the factors that could affect estimated compliance costs of an emission reduction measure is the timing of its implementation. Hypothetically, if a short compliance period were contemplated for a set of sources, and if the short compliance

[31] *EPA Air Pollution Control Cost Manual—Sixth Edition* (EPA 452/B–02–001), EPA Office of Air Quality Planning and Standards, Research Triangle Park, NC, Jan 2002.

[32] See: U.S. EPA 2006. *Regulatory Impact Analysis for the Particulate Matter National Ambient Air Quality Standards.* Air Benefits and Cost Group, Office of Air Quality Planning and Standards, Research Triangle Park, NC, October 6, 2006. Appendix A provides an analysis of estimated benefits and costs of attaining the 1997 PM NAAQS standards in 2015.

period resulted in high demand for a limited supply of labor or other resources, compliance costs could be higher than if the same measure were implemented by a later compliance date. In such a case it may be reasonable for the State to find that the measure is reasonable only if implemented by the later date.

If a source contends that a source-specific RACT level should be established because it cannot afford the technology that appears to be RACT for other sources in its source category, the source can support its claim with such information as:

—Fixed and variable production costs ($/unit)
—Product supply and demand elasticity,
—Product prices (cost absorption vs. cost pass-through),
—Expected costs incurred by competitors,
—Company profits once the technology or measure is in operation (considering the annualized costs and the marginal costs of alternative technologies and measures),
—Employment costs, and
—Any other unique factor(s) particular to the individual source.

Finally, the EPA clarifies that if the State demonstrates through economic analysis that the imposition of the measure would cause unacceptable economic disruption for the local economy, that is, a plant shutdown or a severe curtailment in plant employment or output, a State may reject the measure as not reasonable to reach attainment as expeditiously as practicable.

c. Comments and Responses

Comment: Some commenters agreed with EPA's proposal not to establish presumptive cost-effectiveness thresholds.

Response: The EPA agrees with the commenters.

Comment: A number of commenters expressed concerns over the references to health benefits as a consideration in whether measures are technically or economically available. Some commenters believed this is a consideration not authorized by the CAA. Others believed that consideration of benefits, in combination with EPA's estimates of benefits per ton, would have the effect of converting RACT to more stringent LAER levels. Some commenters expressed concerns whether States had the resources or expertise to conduct cost-benefit analyses for this purpose.

Response: The EPA wishes to clarify that the reference to health benefits does not mean that a cost-benefit, or a detailed health benefits assessment, is a necessary part of a control strategy demonstration. We also wish to clarify that EPA is not requiring that the costs of all technologies and measures for $PM_{2.5}$ and precursors be deemed acceptable at any dollar/ton levels at or below the calculated monetized benefits per ton of reduction. We do, however, continue to believe that the significant benefits associated with $PM_{2.5}$ ambient reductions is a relevant consideration in control strategy development. The EPA disagrees that this limited consideration of benefits would convert the RACT process to the equivalent of LAER.

Comment: One commenter objected to EPA's proposed requirement that States consider competitive factors such as production costs, demand elasticity, product prices, and cost incurred by competitors in the determination of RACT. The commenter believed that this information is generally not accessible to States or industrial facility owners, and is not necessary for a RACT determination.

Response: The EPA generally disagrees that this type of information is unavailable. For example, EPA calculates or reviews this type of data on a regular basis as part of our work on MACT, NSPS, and other emissions standards. A document that describes these types of analyses and the data used to prepare them is the OAQPS Economic Resource Manual found at *http://www.epa.gov/ttn/ecas/analguid.html.* EPA believes that this issue is most relevant to category-wide RACT rules where a source seeks a case-by-case exemption. Further, EPA believes most RACT determinations will be developed through case-by-case analyses rather than rules affecting entire source categories. Accordingly, this analysis likely will be relevant in few cases.

6. What Specific Source Categories and Control Measures Should a State Evaluate When Determining RACT and RACM for a Nonattainment Area?

a. Background

Section 172 does not provide a specific list of source categories and control measures that must be evaluated for RACT and RACM for $PM_{2.5}$. However, section 172(c)(3) indicates that the attainment plan must include a ''comprehensive, accurate, current, inventory of actual emissions from all sources of the relevant pollutant.'' This indicates that States should look broadly at the different types of sources in the nonattainment area. We recognize that $PM_{2.5}$ is a new NAAQS without a long history of implementation as with ozone. Therefore, we included a list of potential RACM measures in the preamble to the proposed rule, based upon a review of information about the contribution of various sources to emissions inventories and a review of potential control measures for such sources. We requested comment on the specific sources and potential control measures recommended for RACM analysis on this list. Based on comments received and additional information available to EPA since the proposal, we have made some changes to the list. We also refer to this list of potential ''RACT and RACM'' measures for the combined approach to RACT and RACM in the final rule.

In the preamble to the proposed rule, EPA indicated that due to the short time available, it does not plan to develop new control techniques guidance (CTG) or ACT documents specifically for purposes of $PM_{2.5}$ implementation. The EPA indicated that other information was available on control technologies, and EPA also indicated its intention to maintain an updated list of references for new $PM_{2.5}$ control technology information.

b. Final Rule

Emission reduction measures constituting RACM should be determined on an area-by-area basis. We believe that a State should consider each of the measures listed in this section to determine if each measure is reasonably available in the applicable nonattainment area. However, we do not presume that each of these measures is reasonably available in each nonattainment area.

We recommend that each State use the list of source categories in this section as a starting point for identifying potentially available control strategies (regulatory and voluntary) for a nonattainment area. States are encouraged and expected to add other potentially available measures to the list based on its knowledge of the particular universe of emissions sources in the area and comments from the general public. We expect that, depending on the potential measure being analyzed, the State's degree of evaluation will vary as appropriate. Detailed information on emission control technologies is available from a number of sources.[33] The EPA intends to maintain a website with links to sources of information for

[33] There are a number of sources of information on technologies for reducing emissions of $PM_{2.5}$ and its precursors. Links are provided to a number of national, state and local air quality agency sites from EPA's $PM_{2.5}$ Web site: *http://www.epa.gov/pm/measures.html.*

controlling emissions of direct particulate matter and PM precursors.

As discussed in section II.J.5. above, EPA recognizes that control technology guidance for certain source categories has not been updated for many years. Section 183(c) of the CAA, which addresses control technologies to address ozone nonattainment problems, requires EPA to ''revise and update such documents as the Administrator determines necessary.'' As new or updated information becomes available States should consider the new information in their RACT determinations. A State should consider the new information in any RACT determinations or certifications that have not been issued by the State as of the time such updated information becomes available.

Stationary Source Measures

—Stationary diesel engine retrofit, rebuild or replacement, with catalyzed particle filter

—New or upgraded emission control requirements for direct $PM_{2.5}$ emissions at stationary sources (e.g., installation or improved performance of control devices such as a baghouse or electrostatic precipitator; revised opacity standard; improved compliance monitoring methods)

—Improved capture of particulate emissions to increase the amount of $PM_{2.5}$ ducted to control devices, and to minimize the amount of $PM_{2.5}$ emitted to the atmosphere, for example, through roof monitors

—New or upgraded emission controls for $PM_{2.5}$ precursors at stationary sources (e.g., SO_2 controls such as wet or dry scrubbers, or reduced sulfur content in fuel; desulfurization of coke oven gas at coke ovens; improved sulfur recovery at refineries; increasing the recovery efficiency at sulfuric acid plants)

—Energy efficiency measures to reduce fuel consumption and associated pollutant emissions (either from local sources or distant power providers)

—Measures to reduce fugitive dust from industrial sites

Mobile Source Measures

—Onroad diesel engine retrofits for school buses,[34] trucks and transit buses using EPA-verified technologies

—Nonroad diesel engine retrofit, rebuild or replacement, with catalyzed particle filter [35]

—Diesel idling programs for trucks, locomotive, and other mobile sources [36]

—Transportation control measures (including those listed in section 108(f) of the CAA as well as other TCMs), as well as other transportation demand management and transportation systems management strategies [37]

—Programs to reduce emissions or accelerate retirement of high emitting vehicles, boats, and lawn and garden equipment

—Emissions testing and repair/maintenance programs for onroad vehicles

—Emissions testing and repair/maintenance programs for nonroad heavy-duty vehicles and equipment [38]

—Programs to expand use of clean burning fuels [39]

—Low emissions specifications for equipment or fuel used for large construction contracts, industrial facilities, ship yards, airports, and public or private vehicle fleets

—Opacity or other emissions standards for ''gross-emitting'' diesel equipment or vessels

Area Source Measures

—New open burning regulations and/or measures to improve program effectiveness such as programs to reduce or eliminate burning of land clearing vegetation

—Programs to reduce emissions from woodstoves and fireplaces including outreach programs, curtailments during days with expected high ambient levels of $PM_{2.5}$, and programs to encourage replacement of woodstoves when houses are sold

—Controls on emissions from charbroiling or other commercial cooking operations

—Reduced solvent usage or solvent substitution (particularly for organic compounds with 7 carbon atoms or more, such as toluene, xylene, and trimethyl benzene)

Category-Specific Guidelines on innovative approaches. The EPA has issued a number of category specific guidelines on approaches to taking into account innovative approaches to emissions reductions for purposes of SIPs. Categories currently covered by these guidelines include: (1) Electric-sector Energy Efficiency and Renewable Energy Measures; (2) Long Duration Switch Yard Locomotive Idling; (3) Long Duration Truck Idling; (4) Clean Diesel Combustion Technology; and (5) Commuter Choice Programs. See *http://www.epa.gov/ttn/airinnovations/measure_specific.html.*

c. Comments and Responses

Comment: Some commenters recommended that EPA provide new CTGs or other control technology review documents for purposes of assisting States to address $PM_{2.5}$ and its precursors, because the information in some current documents is out-dated.

Response: The EPA recognizes that issuance of new or updated CTGs specifically tailored for $PM_{2.5}$ would be useful. Unfortunately, limitations on time and resources preclude EPA from developing such CTGs in advance of the SIP submission date. The EPA cannot delay the statutorily specified outer date for SIP submission. However, EPA believes that there are already many sources of information and guidance on key source categories. To the extent that States need to examine potential control measures for sources never addressed before in any area or other context for a previous NAAQS, EPA anticipates that it will work closely with States during the process of plan development and approval to ensure an appropriate approach.

Comment: A number of commenters expressed concerns with references to the STAPPA and ALAPCO *Menu of Options* document. Some commenters believed that this document must be subject to formal review and comment to ensure appropriate stakeholder input.

Response: The language in the final preamble has been changed to refer to a Web site EPA maintains that provides access to a variety of information sources regarding control technologies that may be useful to States to consider in developing their $PM_{2.5}$ SIPs. These links include evaluations developed by government and nongovernment organizations. One such source with potentially useful information is the STAPPA and ALAPCO *Menu of Options.* However, EPA is not specifically endorsing any of the specific evaluations as being appropriate in any specific situation. Rather, we think documents such as the

[34] See Clean School Bus USA program at *http://www.epa.gov/cleanschoolbus/.* See also: ''What You Should Know About Diesel Exhaust and School Bus Idling,'' (June 2003, EPA420–F–03–021) at *http://www.epa.gov/otaq/retrofit/documents/f03021.pdf.*

[36] See EPA's voluntary diesel retrofit program Web site at *http://www.epa.gov/otaq/retrofit/idling.htm.*

[37] See EPA's Web site on transportation control measures at *http://www.epa.gov/otaq/transp/traqtcms.htm.*

[38] See EPA's Web site on nonroad engines, equipment, and vehicles at *http://www.epa.gov/otaq/nonroad.htm.*

[39] Fuels adopted in SIPs must be consistent with the Energy Policy Act of 2005 and EPA guidance on SIP-approved boutique fuels at 71 FR 78192 (December 28, 2006).

Menu of Options provide potentially useful ideas. Specifically, States would need to assess which items on the menu are applicable in their areas, and will have to assess the costs of applying controls locally. Accordingly, there would be ample opportunity for public review of the State's analysis of the local cost and air quality impacts of any measure listed in the document which is included in a State's SIP. The EPA is not requiring that States adhere to the list of measures in the *Menu of Options.* The EPA does not in any way mean to imply that the measures in the *Menu of Options* are presumed to be RACM, merely that they are potential controls for areas to consider. The *Menu of Options* has no regulatory significance and thus need not be issued through notice-and-comment rulemaking. The EPA notes, however, that the *Menu of Options* does provide a broad list of potential sources and measures that can help inform States in the development of their plans. Similarly, our own list of potential measures is not intended to be a categorical list of measures which States must adopt, rather it is intended to provide guidance about the types of sources and measures that States can consider in constructing their attainment plans. The EPA emphasizes that whether a source category or potential measure is or is not on this list is simply not conclusive as to whether a given measure is appropriate to consider in the RACT and RACM analysis. That can be determined only through the State's development of the attainment plan, and EPA's evaluation of such plan.

Comment: A commenter representing the paper industry interpreted the proposed rule as requiring electrostatic precipitator and tighter sulfur-in-fuel requirements for the forest products industry. The commenter believed that EPA was creating limits for such sources without adequate rulemaking process.

Response: The EPA disagrees that the listing of control technologies in the table in the rule creates a ''rebuttable presumption.'' Rather, the table identifies potential opportunities for emissions reductions which should be reviewed in light of technical and economic feasibility, and which a State should consider in a list of possible RACT and RACM measures for purposes of attaining the standards as expeditiously as practicable. The EPA is currently conducting a sector-based approach to the paper industry. One of the goals of the sector initiative on pulp and paper is to work with the industry to identify reductions in SO_2 and $PM_{2.5}$ that will assist us in meeting the NAAQS, considering facility locations, magnitude of emissions, emission stream characteristics, and cost effectiveness of controls.

Comment: A number of commenters believed that EPA should develop not only a list of measures to consider for RACM, but should develop a list of mandatory measures that States should include, particularly for areas with attainment dates more than 5 years after designation.

Response: See discussion in section II.D.3 regarding rule requirements for attainment date extensions and the issue of whether certain measures should be mandatory in order for an area to receive an extension.

Comment: Some commenters believed that the list of possible measures was deficient in not including sources of $PM_{2.5}$ and $PM_{2.5}$ precursors from agricultural sources. One commenter believed the list is incomplete without identifying the contribution of ammonia emissions associated with livestock, poultry, and crop fertilizers.

Response: As we indicated in the proposal, we included a list of potential RACM measures in the preamble to the proposed rule, based upon a review of information about the contribution of various sources to the emissions inventories and a review of potential control measures for such sources. We did not identify emissions from agricultural sources in this review. Because ammonia is not presumed to be a $PM_{2.5}$ precursor unless identified for a specific area by the State or EPA, regulation of ammonia emissions from agricultural sources may not be necessary.

We also note that the agricultural industry presents unique challenges to regulators given the nature of relevant emissions sources. Moreover, we currently lack good methods to quantify agricultural emissions, and we do not fully understand their contribution to nonattainment problems. We have entered into an agreement with several animal producer sectors to monitor animal feeding operations to develop better tools to assess emissions from this industry. Hopefully, these tools will enhance our knowledge of agricultural emissions and their contribution to nonattainment problems. Until emissions from these sources are better understood, States should be judicious in determining whether any specific measure is RACT/RACM for this industry.

The EPA recognizes that the United States Department of Agriculture (USDA) has been working with the agricultural community to develop conservation systems and activities to control coarse particle emissions. Based on current ambient monitoring information, these USDA-approved conservation systems and activities have proven to be effective in controlling these emissions in areas where coarse particles emitted from agricultural activities have been identified as a contributor to a violation of the PM_{10} NAAQS. The EPA has found that where USDA-approved conservation systems and activities have been implemented, these systems and activities have satisfied the Agency's reasonably available control measure and best available control measure requirements for areas needing to attain the PM_{10} standards.

The EPA believes that in the future, certain USDA-approved conservation systems and activities that reduce agricultural emissions of fine particles may be able to satisfy the requirements of applicable sources to implement reasonably available control measures for purposes of attaining the $PM_{2.5}$ NAAQS. The EPA will work with States to identify appropriate measures to meet their RACM requirements, including site-specific conservation systems and activities. The EPA will continue to work with USDA to prioritize the development of new conservation systems and activities; demonstrate and improve, where necessary, the control efficiencies of existing conservation systems and activities; and ensure that appropriate criteria are used for identifying the most effective application of conservation systems and activities.

Comment: Some commenters raised concerns about a statement in the proposal that ''[i]n addressing a nonattainment area having military training, testing and operational activities occurring within it, the State should not need to target these activities for emission reductions.'' Some commenters interpreted this statement as an exemption from any emission reduction requirements for military sources.

Response: The statement in the proposal was not intended as an exemption for all military activities. Emissions potentially contributing to $PM_{2.5}$ concentrations at military installations originate from a variety of sources: basic operational activities (such as power generation, other fuel combustion, and transportation to and from residences, offices, and schools); and from field training and testing activities (such as personnel training, obscurants used in training, operation of nonroad vehicles and equipment, and related prescribed burning operations). The EPA believes that in evaluating emissions for a specific nonattainment

area having military activities occurring within it, the State should consult with DOD for information on the nature of these activities and their associated emissions.

With regard to military training activities specifically, such activities are periodic in nature, and when they do occur, the principal type of emissions generated by these activities is dust (i.e. inorganic direct PM emissions) from field operations. Other pollutants may be emitted to a lesser degree from certain onroad and nonroad motor vehicles. While military training activities may contribute some degree of primary $PM_{2.5}$ emissions to certain nonattainment area inventories, the fugitive dust generated from military training activities is predominantly composed of coarse PM rather than fine PM.

Based on data from the $PM_{2.5}$ speciation monitoring network operated by EPA and the States, the contribution of inorganic dust to total $PM_{2.5}$ mass on an annual average basis is relatively low in most nonattainment areas, on the order of 0.5 to 1.5 micrograms per cubic meter (generally 10% or less of total $PM_{2.5}$ mass). Dust from military training activities would be a subset of these levels. Depending on the available information and specific circumstances for a particular area, a State could find in its SIP development analyses that direct $PM_{2.5}$ emissions from military training activities do not significantly contribute to $PM_{2.5}$ concentrations in the nonattainment area, and therefore would not need to target military training activities for emission reductions in its attainment plan.[40]

7. How Should States Consider EGU Reductions for CAIR in Meeting RACT/RACM Requirements?

a. Background

In section III.I.11 of the preamble to the proposed rule, we discussed the nature of the SO_2 and NO_X RACT obligations of electric generating unit (EGU) sources in states subject to the CAIR emission reduction requirements. The CAIR rulemaking was finalized in March 2005 and published at 70 FR 25221 (May 12, 2005). CAIR requires 28 states and the District of Columbia to significantly reduce emissions of SO_2 and/or NO_X. The 26 jurisdictions in the CAIR $PM_{2.5}$ region are required to reduce annual emissions of SO_2 and NO_X, and the 26 jurisdictions in the CAIR ozone region are required to reduce seasonal emissions of NO_X. These jurisdictions also have the option of participating in EPA-administered annual SO_2, annual NO_X, and seasonal NO_X cap-and-trade programs (the CAIR trading programs) to meet these emission reduction requirements. In addition, in March 2006, EPA promulgated a Federal implementation plan (FIP) to implement CAIR in these jurisdictions until they have EPA approved CAIR SIPs in place (71 FR 25328, April 28, 2006). The FIP adopts, as the control measure, the CAIR trading programs slightly modified to allow for Federal instead of State implementation. When fully implemented, CAIR will reduce SO_2 emissions in these jurisdictions by over 70 percent and NO_X emissions by over 60 percent from 2003 levels. This will result in $85 to $100 billion in health benefits and nearly $2 billion in visibility benefits per year by 2015 and will substantially reduce premature mortality in the eastern United States. The benefits will continue to grow over time as the program is fully implemented (i.e., the SO_2 emission bank is depleted and the final cap is met), and as growth in populations and the aging of the population continues (which increases the susceptible population).

Sources subject to cap-and-trade programs such as the CAIR trading programs generally have the option of installing emissions control technology, adopting some other strategy to reduce emissions, or purchasing emissions allowances and thereby effectively paying other sources covered by the cap to reduce emissions. In the proposal, we noted that a number of EGUs expected to be covered by the CAIR trading programs are located in nonattainment areas. Based on emissions projections for 2010 and 2015 using the Integrated Planning Model (IPM), some of these EGUs are expected to comply with CAIR by purchasing allowances under the trading program and some are expected to comply by installing emission controls.

The proposal also described our past experience with the implementation of the NO_X SIP Call and our belief that many power companies will develop their strategies for complying with CAIR based, in part, on consultations with State and local air quality officials in order to address local $PM_{2.5}$ and ozone attainment planning needs. The EPA suggested that consultations on location of CAIR controls would be timely during State development of the CAIR SIP, which is due in 2006, prior to the April 2008 deadline for submitting $PM_{2.5}$ nonattainment area SIPs.

The EPA proposed a determination that in States that fulfill their CAIR SO_2 emission reductions entirely through EGU emission reductions (i.e. without reductions from non-EGU sources or allowing non-EGU sources to opt-in to the CAIR SO_2 trading program), participation in the CAIR SO_2 trading program would satisfy the SO_2 RACT requirement for the EGU sources. The EPA also proposed that in states that fulfill their CAIR NO_X emission reductions entirely through EGU emission reductions, CAIR would satisfy NO_X RACT for the EGU sources, provided that those sources with existing selective catalytic reduction (SCR) emission control technology installed on their boilers operate that technology on a year-round basis beginning in 2009. Note that direct $PM_{2.5}$ emissions are not addressed by the CAIR program, and EPA did not propose any determination that compliance with CAIR would satisfy RACT for direct $PM_{2.5}$ emissions. The proposal included a discussion of the rationale for these proposed determinations for SO_2 and NO_X, and requested comments on the issue.

b. Final Rule

As discussed in section II.F.2 on our overall policy for RACT and RACM, we consider an area's obligation to implement RACT to be part of the area's overall RACM obligation—to adopt those reasonably available measures needed to reach $PM_{2.5}$ attainment as expeditiously as practicable. The final rule also reflects this combined RACT/RACM approach regarding EGU control obligations under CAIR and the extent to which meeting CAIR also satisfies a source's RACT and RACM requirements for attainment.

Specifically, the final rule includes a presumption that in States that fulfill their CAIR SO_2 emission reduction requirements entirely through EGU emission reductions (i.e. without reductions from non-EGU sources or allowing non-EGU sources to opt in to the CAIR SO_2 trading program), compliance by EGU sources with an EPA-approved CAIR SIP or a CAIR FIP would satisfy their SO_2 RACT/RACM requirements for attaining the fine particle NAAQS. This section also includes a presumption that in States

[40] Windblown dust from agricultural tilling activities also can be a periodic source of inorganic PM in some areas. In some cases such dust would be expected to be predominantly composed of coarse PM rather than fine PM. Depending on the available information and specific circumstances for a particular area, it is possible that a State could find in its SIP development analyses that direct $PM_{2.5}$ emissions from agricultural tilling activities do not significantly contribute to annual average $PM_{2.5}$ concentrations in the nonattainment area, and therefore would not need to require emission reductions from agricultural tilling activities in the plan for attaining the annual standard. However, States should be mindful of the contribution of these sources to 24-hour fine particle concentrations.

that are subject to CAIR annual NO_X emission reduction requirements and fulfill these requirements entirely through EGU emission reductions (i.e. without reductions from non-EGU sources or allowing non-EGU sources to opt in to the CAIR annual NO_X trading program), compliance by EGU sources with an EPA-approved CAIR SIP or a CAIR FIP would satisfy the NO_X RACT/RACM requirement for the $PM_{2.5}$ NAAQS, provided that the sources with existing selective catalytic reduction (SCR) emission control technology installed on their boilers operate that technology on a year-round basis beginning in 2009. This final position is based on a number of factors identified in the proposal and discussed below.

Many $PM_{2.5}$ nonattainment areas are projected to achieve significant SO_2 and NO_X reductions under the CAIR program. We do not believe that requiring source-specific RACT/RACM controls on specified EGUs in nonattainment areas would reduce total SO_2 and NO_X emissions from sources covered by CAIR below the regionwide levels that will be achieved under CAIR alone. Nor do we believe that ''beyond CAIR'' EGU controls for SO_2 and NO_X are ''reasonably available'' control measures for most areas within the CAIR Region. Accordingly, most States need not evaluate additional control measures on EGUs to satisfy RACT/RACM requirements as explained above.

As discussed previously, we are not requiring that States impose RACT on any specific size or type of source. Instead, States must conduct a RACT/RACM analysis considering measures that are ''reasonably available'' to meet the overarching requirement to attain the standards as expeditiously as practicable. Thus, the final rule imposes no specific requirement on States to impose RACT/RACM on EGUs.

Nonetheless, in evaluating RACT/RACM for EGUs, EPA believes it is appropriate for States (states that achieve all reductions from EGUs) to consider the special attributes of that group of facilities including the unique interrelated nature of the power supply network, and their participation in the CAIR program. For EGUs in the CAIR region, based upon the presumption explained here, States may define RACT/RACM as the CAIR level of control on the collective group of sources in the region rather than impose a specific level of control on an individual source. This approach is similar to the Agency's past ''bubble'' policy, as discussed in section (c) addressing comments on the proposal.

As discussed more fully in the CAIR final rulemaking notice, EPA has set the 2009 and 2010 CAIR caps for SO_2 and NO_X at a level that will require EGUs to install emission controls on the maximum total capacity on which it is feasible to install emission controls by those dates. The EPA concluded that the CAIR compliance dates represent an aggressive schedule that reflects the limitations of the labor pool, and equipment/vendor availability, and need for electrical generation reliability for installation of emission controls.

Although the actual SO_2 cap does not become effective until 2010, we designed banking provisions in CAIR so that covered EGUs will begin to reduce their SO_2 emissions almost immediately after CAIR is finalized, and will continue steadily to reduce their emissions in anticipation of the 2010 cap and the more stringent cap that becomes effective in 2015. The 2015 SO_2 and NO_X caps are specifically designed to eliminate all SO_2 and NO_X emissions from EGUs that are highly cost effective to control (the first caps represent an interim step toward that end).

Moreover, we predicted that the majority of large coal-fired utilities will install advanced control technologies under CAIR because the larger and higher emitting source offer an opportunity to obtain more cost-effective emissions reductions. We expect that the largest-emitting sources will be the first to install SO_2 and NO_X control technology and that such control technology will gradually be installed on progressively smaller-emitting sources until the ultimate cap is reached. As a result, few, if any coal-fired units with greater than 600 MW of operating capacity should operate in $PM_{2.5}$ nonattainment areas without advanced control after full implementation of CAIR. Of the remaining units operating without advanced pollution controls, a great many of these units will have operating capacities below 300 MW. We predict that these units ''will be utilized less often,'' and ''typically have baghouses and electrostatic precipitators for particulate control, have combustion controls for NO_X control, and burn low-sulfur coal.'' See ''Contributions of CAIR/CAMR/CAVR to NAAQS Attainment: Focus on Control Technologies and Emission Reductions in the Electric Power Sector,'' Office of Air and Radiation, U.S. Environmental Protection Agency, April 18, 2006 (available at *http://www.epa.gov/airmarkets/cair/analyses/naaqsattainment.pdf*). In light of these expected results, we generally believe that the cost to install additional controls on these smaller units would be unreasonable.

We are also concerned that if States require specific EGUs to install advanced pollution control measures, it could interfere with the market-based incentives inherent in the cap and trade program. This could increase the cost of compliance and shift the location of the units that would otherwise opt to install advanced emissions controls. Such a result may be counterproductive to that State's attainment efforts, as the State may forego a larger quantity of more beneficial reductions in transported pollutants, in exchange for a smaller quantity and less beneficial reduction in local emissions. Moreover, it may reduce the benefits expected in other nonattainment areas as well. Accordingly, even if a State found the cost to control an individual unit acceptable on a cost per ton basis, the potential overall disbenefit of control may nonetheless make imposition of the control not ''reasonably available.''

The EPA finds that the control installations projected to result from CAIR NO_X and SO_2 caps in 2009 and 2010 are as much as feasible from EGUS across the CAIR Region by those dates. In fact, if states chose to require smaller-emitting sources in nonattainment areas to meet source-specific RACT requirements by 2009, they would likely use labor and other resources that would otherwise be used for emission controls on larger sources. Because of economies of scale, more boiler-makers may be required per megawatt of power generation for smaller units than larger units. In this case, the imposition of source-specific RACT/RACM on smaller emitting sources by 2009 could actually reduce the amount of banking that would otherwise occur and result in higher SO_2 emissions in 2009 as compared to the level that would result from implementation of CAIR alone.

In any event, the imposition of source-specific control requirements on a limited number of sources also covered by a cap-and-trade program would not reduce the total regionwide emissions from sources subject to the program. Under a cap-and-trade program such as CAIR, a given number of allowances are issued in order to achieve a given emission level. Source-specific control requirements within the CAIR program may affect the temporal distribution of emissions (by reducing banking and thus delaying early reductions) or the spatial distribution of emissions (by moving them around from one place to another), but they would not affect total regional emissions under the program. If source-specific requirements were targeted at the units

that could be controlled most cost-effectively, then the imposition of source-specific controls would likely achieve the same result as the cap-and-trade program. If not, however, the imposition of source-specific requirements would make any given level of emission reduction more costly than it would be under the cap-and-trade program alone. Thus, the imposition of source-specific RACT on EGUs covered by CAIR would not reduce total regionwide emissions, but would likely achieve emission reductions under the program in a more costly way.

Given the considerations described above, we think that in many areas additional controls on EGUs generally would not be ''reasonably available.'' Notwithstanding these conclusions, we recognize that States are in the best position to determine how best to achieve attainment with the $PM_{2.5}$ NAAQS in light of local needs and conditions. As we acknowledged in our proposed rule, power plant operators typically have ongoing relationships with the State and local officials involved in air quality planning. We expect that power plants will continue to collaborate with State officials to determine how best to address multiple air quality goals, and which plant locations to control under CAIR, considering local $PM_{2.5}$ and ozone attainment needs.

The EPA expects States and local air agencies to identify reasonably available control measures that are necessary and reasonable to attain the standards as expeditiously as practicable; and that after consulting with power companies, the State may conclude that establishing additional ''beyond CAIR'' emission control requirements on specific sources in nonattainment areas is warranted to provide for attainment as expeditiously as practicable. Nevertheless, in preparing the overall attainment demonstration, States should be aware of the expected benefits of the market-based incentives of the CAIR program, the cost effectiveness of control, feasibility of implementation, and any disbenefits that would result from requiring ''beyond CAIR'' controls on any specific EGU before concluding that additional controls on EGUs are ''reasonably available'' and necessary to satisfy RACT/RACM requirements.

Year-round NO_X controls. In the CAIR final rulemaking notice, EPA found that the operation of existing SCRs on a year-round basis, instead of operating them only during the ozone season, could achieve NO_X reductions at low cost relative to other available NO_X controls. The EPA projected that power generators would employ this control measure to comply with CAIR SIPs. Based on this control opportunity, EPA estimated the average cost of non-ozone-season NO_X control at $500/ton. These considerations support a finding that RACT should include year-round operation of existing SCRs that are located in $PM_{2.5}$ nonattainment areas. Because all $PM_{2.5}$ nonattainment areas violate the annual form of the $PM_{2.5}$ standard and public health can be affected by high $PM_{2.5}$ levels in the winter as well as the summer, we believe that year-round operation of existing SCR that are located in nonattainment areas where NO_X is an attainment plan precursor will provide additional health benefits for relatively low dollar cost per ton of pollutant reduced.

In the proposal notice, EPA proposed to define ''existing'' SCRs as those units that were in place by the date of the proposed rule (November 1, 2005). We selected this date rather than the final date to avoid creating an incentive to delay installation of new SCR. Today, we finalize our proposed approach with one clarification. To avoid confusion over the proper interpretation of the phrase ''in place,'' we are clarifying that an existing SCR is one which is fully installed and capable of operation by November 1, 2005.

We also proposed that these existing SCR begin year-round operations no later than January 1, 2009 to qualify as RACT/RACM under our presumptive approach. We noted that year round operation of existing SCR involves little to no alteration of existing equipment, and that EGUs could conduct any required work during normal outages. Today, after taking these factors into account, we finalize our proposed rule. The year-round operation requirement, however, will not be federally enforceable to individual EGUs until EPA approves a State's SIP including the requirement.

c. Comments and Responses

Comment: Some commenters supported the proposed determination described in section (a) that in States that fulfill their CAIR SO_2 emission reduction requirements entirely through EGU emission reductions (i.e. without reductions from non-EGU sources or allowing non-EGU sources to opt in to the CAIR SO_2 trading program), compliance by EGU sources with an EPA-approved CAIR SIP or a CAIR FIP would satisfy the SO_2 RACT requirement for the sources; and in States that are subject to CAIR annual NO_X emission reduction requirements and fulfill these requirements entirely through EGU emission reductions (i.e. without reductions from non-EGU sources or allowing non-EGU sources to opt in to the CAIR annual NO_X trading program), compliance by EGU sources with an EPA-approved CAIR SIP or a CAIR FIP would satisfy the NO_X RACT requirement for the sources, provided that the sources with existing selective catalytic reduction (SCR) emission control technology installed on their boilers operate that technology on a year-round basis beginning in 2009. One commenter supported EPA's approach so long as States may pursue additional reductions from EGUs if needed for attainment as expeditiously as practicable. A number of other commenters opposed the proposed determination regarding RACT for EGUs based on a number of issues.

Response: Based on the rationale described in the sections above, the final rule includes a presumption that compliance with CAIR satisfies SO_2 and NO_X RACT/RACM requirements for EGUs in many areas. Nonetheless, States can require ''beyond CAIR'' EGU controls if a State determines that it is a necessary and reasonable means to attain the $PM_{2.5}$ standards. Comments opposing this approach are addressed in more detail below.

Comment: A number of commenters objected to the proposed determination, arguing that it would result in greater control requirements and economic burden on non-EGU sources located in nonattainment areas. These commenters urged EPA to adopt a final rule that provides for implementing the most cost-effective controls necessary to attain the standard. They assert that with the proposed finding that compliance with CAIR satisfies RACT for EGUs, the proposed rule would not provide for the most cost-effective approach to attainment. They argue EPA and States should develop cost-effectiveness guidance that includes all stationary source control measures and they should develop SIPs based on the most economic means to attain the standard. They make several arguments to support this position. The commenters asserted that if an EGU control is more cost-effective than a non-EGU control, the EGU should be subject to ''beyond-CAIR'' controls. They also asserted that if EPA chooses to consider the CAIR rule as satisfying SO_2 and NO_X RACT for EGUs, then other sources should not be subjected to control costs greater than those found reasonable under CAIR (i.e., $800/ton). They believe it would be inequitable to require smaller sources to pay a higher cost for emissions reductions than larger sources, which are a more significant

contributor to the problem and which may be able to make more cost-effective emission reductions. One commenter also suggested that EPA should authorize a presumption that emissions reductions required on electric utilities under the CAIR will be equivalent to RACT only if a particular source in a CAIR State has installed controls that achieve the average level of control that EPA has projected will occur for the particular pollutant under the CAIR requirements.

Response: The EPA has determined that implementation of the CAIR trading program represents highly cost-effective controls that will achieve widespread regional SO_2 and NO_X emissions reductions from EGUs and will provide significant air quality benefits for ozone and $PM_{2.5}$ nonattainment areas. In developing attainment SIPs and identifying RACM, States will need to consider additional cost-effective and reasonable controls to reach attainment as expeditiously as practicable. The EPA does not agree with the commenter's argument that controls on non-EGUs should be no more than the projected cost of EGU controls under CAIR. The EPA expects that in order to achieve attainment as expeditiously as practicable, some States may need to adopt control measures for some sources which cost more per ton but which still are considered to be reasonable and cost-effective.

In addition, States must consider the economic feasibility of implementing a given control measure. Because of facility-specific factors, EPA believes it would be inappropriate to establish a threshold of control effectiveness (e.g. dollars per ton) based on control of EGUs and apply this threshold to all source categories. The ability of a source to cost-effectively reduce emissions is dependent on case-specific factors, including the ability of the given source to sustain the cost of control, and prevailing costs in the specific geographical location. A direct correlation between the size of an emissions source and the economic feasibility of controls for that source and location does not necessarily exist.

We also disagree with the commenter who suggests that RACT requirements should only be satisfied if a source achieves an average level of control that EPA projects to occur under CAIR. The EPA maintains that the presumption that CAIR satisfies SO_2 and NO_X RACT/RACM for EGUs in most areas is an appropriate policy. As discussed further below, we have always recognized that States could determine RACT for a single source or group of sources.

Comment: A number of commenters opposed the proposed determination that CAIR would satisfy the SO_2 and NO_X RACT requirement for EGUs. The commenters argued that this determination is unlawful, that it does not comply with section 172(c)(1) of the CAA which requires RACT (i.e. controls that are technologically and economically feasible) ''at a minimum'' for all existing sources in the nonattainment area, that it would allow very large stationary sources to escape cost-effective controls entirely, and that it is largely based on the legally-irrelevant contention that CAIR will reduce emissions more cost-effectively than RACT. They claim that EPA has no authority to displace the Congressionally-mandated RACT requirement, that CAIR was designed to address regional pollution transport (not to be an attainment strategy), and that EPA should remove these proposed provisions in the final rule. Commenters claim that the EPA's proposed approach to allow EGU emissions to be addressed solely through CAIR would undermine states' efforts to meet the Federal $PM_{2.5}$ health standard, particularly when EGU sources are among the most cost-effective to control. Another commenter claimed that EPA's proposal allowing States that choose to fulfill their CAIR requirements entirely through emission reductions from EGUs to also use CAIR to satisfy their SO_2 and NO_X $PM_{2.5}$ RACT requirements, thereby equating these two requirements for the EGU sector, is flawed. This commenter argued that allowing a cap-and-trade program, such as the CAIR, to substitute for the RACT requirement undermines the effectiveness of the controls by allowing facilities to use allowances to offset emissions, rather than control them at the source. The purchase of allowances, they assert, does not satisfy RACT requirements.

Response: The EPA disagrees with these comments. The final rule does not displace the RACT requirement for any sources. Instead, EPA is exercising its authority to interpret the section 172 RACT and RACM requirements for the purposes of implementing the 1997 $PM_{2.5}$ standards. For the reasons described in section (b) above, we believe that States can rely on EPA's presumption that compliance with a CAIR SIP or FIP, meeting certain requirements, will satisfy the RACT/RACM requirement for certain EGU sources. The EPA historically issued control technology guidelines setting forth presumptive levels of emissions control that satisfy the RACT requirement for a given industry. The final rule is similar to this practice in establishing a presumption that SO_2 and NO_X reductions under the CAIR program satisfy the RACT/RACM requirement for EGUs in CAIR States. In identifying reasonably available control measures to ensure attainment as expeditiously as practicable, States will need to take CAIR reductions into account as well as any additional cost-effective reductions that are technologically and reasonably available.

We further find that the attempt by many commenters to characterize CAIR as a strategy to address only regional pollution transport and not an attainment strategy as overly simplistic. The EPA analyses for CAIR show that there are significant air quality benefits projected for individual nonattainment areas as a result of SO_2 and NO_X reductions across the multistate CAIR region. The Act does not prevent States from properly crediting measures that achieve multiple objectives (e.g. regional transport or local nonattainment). Moreover, Section 110(a)(2)(D) requires SIPs to contain adequate provisions to assure that sources in the State do not contribute significantly to nonattainment in any other State. The CAIR rule is an integral element in meeting the States' Section 110 attainment obligations. Accordingly, it is reasonable to incorporate this consideration in determining what measures qualify as RACT/RACM.

Finally, EPA does not interpret the provisions of Section 172(c)(1) related to the RACT requirement as precluding States' use of a cap and trade approach as a means of regulating existing sources and achieving RACT/RACM reductions, especially in light of Congresses' expressed authorization to auction emission rights in Section 172(c)(6).

The EPA has long recognized that RACT need not apply to individual sources. As stated earlier, our early guidance on RACT requirements stated that States could establish RACT for an ''individual sources or *a group of sources.*'' (emphasis added) See Memo. Strelow (Dec. 1976) and 44 FR 71779. Importantly, Congress ratified the early interpretations of RACT and RACM when it enacted the 1990 Amendments. See 42 U.S.C. Section 7515 (Clean Air Act section 193). Our 1986 emissions trading policy also recognized a number of advantages offered through application of a ''bubble'' approach including faster compliance with RACT limits and earlier reductions. Moreover, Courts have upheld EPA's approval of States' use of ''bubbling'' multiple units to meet RACT requirements. See e.g.

Natural Resources Defense Council v. *EPA*, 941 F.2d 1207 (finding that EPA need not adhere to a source specific RACT determination to satisfy RACT requirements and acknowledging EPA's special knowledge and expertise in the area.)

Comment: The EPA's proposal to allow EGU emissions to be addressed solely through CAIR undermines prospectively States' efforts to meet the Federal $PM_{2.5}$ health standard. EGU sources are among the most cost-effective to control.

Response: For the reasons described in section (b) above, EPA believes that States can rely on EPA's presumption that compliance with a CAIR SIP or FIP, meeting certain requirements, satisfies the SO_2 and NO_X RACT/RACM requirement for certain EGU sources. Areas can require ''beyond CAIR'' EGU controls if a State determines that it is a necessary and reasonable means to attain as expeditiously as practicable. Nonetheless, as discussed above, EPA believes that implementation of the CAIR requirements will provide for substantial progress in attaining the $PM_{2.5}$ standards and that States may presume that RACT/RACM requirements are equal to the CAIR level of control.

Comment: CAIR fails to address the need for short-term reductions in $PM_{2.5}$ and precursor emissions on high pollution days. While RACT restricts emissions over a 1-hour to 24-hour period, CAIR only provides for an annual or seasonal cap. Reliance on CAIR therefore fails to recognize the importance of reducing short-term emissions, which was recently highlighted by the EPA's own proposal to tighten the 24-hour $PM_{2.5}$ health standard. Local and short-term adverse air quality effects of $PM_{2.5}$, must be addressed in the final rule by requiring RACT for all major facilities in addition to CAIR.

Response: The CAIR program is oriented toward reducing SO_2 and NO_X emissions in order to reduce air quality concentrations on an annual and seasonal basis. Because all $PM_{2.5}$ nonattainment areas were designated due to violations of the annual standard (and the two designated areas in California also violated the 24-hour standard), the focus of this implementation rule is attainment of the annual standard. CAIR is projected to provide significant air quality benefits in 2010 and 2015 for eastern $PM_{2.5}$ nonattainment areas on both an annual basis and on a 98th percentile 24-hour basis.[41]

Comment: The proposal is silent on the issue of whether EGUs are subject to direct $PM_{2.5}$ emissions RACT requirements. It is critical that RACT be required for all facilities with respect direct $PM_{2.5}$ emissions, regardless of a facility's participation in CAIR.

Response: In the final rule and preamble, EPA has clarified that all EGUs in nonattainment areas are subject to RACT/RACM for direct $PM_{2.5}$ emissions. The presumption described above applies only to SO_2 and NO_X RACT/RACM, not RACT/RACM for direct $PM_{2.5}$ emissions from EGUs.

Comment: The EPA fails to consider the geographical distributional impacts of the emission reductions. Equating CAIR with RACT fails to take into account the substantial contribution that emissions from EGUs within a nonattainment area may make toward that area's $PM_{2.5}$ nonattainment problem. The EPA does not attempt to explain how such a generalized determination satisfies RACT for $PM_{2.5}$.

Response: The establishment of recommended levels for RACT/RACM is an area Congress delegated to the specific expertise of the Agency. Based on our analysis, we conclude that the CAIR emissions caps presumptively represent the level of emissions control achievable through application of ''reasonably available'' control technologies. Nonetheless, in developing attainment plans, each State will evaluate the impact of stationary sources located within the nonattainment area in developing its attainment strategies for the local area.

Comment: A few commenters stated that EPA should explain how this proposal would be implemented for States that request an extension of an attainment date because attaining in 5 years or less is impracticable; i.e., whether EPA would still hold to its interpretation that CAIR equals RACT for EGUs and not require additional reductions from EGUs even if an area cannot attain in 5 years and controls on EGUs could lead it to attain more expeditiously. These commenters argue that, in considering if additional RACT is needed in states that obtain extensions of the attainment deadline after 2010, EPA cannot ignore potential RACT for electric generating units any more than they would be allowed legally to avoid consideration of any other RACT candidates. One commenter is particularly concerned that States would not include EGUs in their RACT determinations and instead require smaller industrial boilers or process heaters to control emissions.

Response: The EPA's determination regarding CAIR and RACT is not limited to areas attaining within five years. The Agency's rationale is presented in the ''final rule'' section above. We disagree that the CAIR–RACT presumptions necessarily shift emission control burdens from EGUs to smaller industry boilers and process heaters because, in implementing the RACM requirement, the State may include an evaluation of control options on those sources as part of their RACT/RACM analyses. As stated above, EPA concluded that the CAIR compliance dates represent an aggressive schedule that reflects the limitations of the labor pool, and equipment/vendor availability, and need for electrical generation reliability for installation of emission controls. Accordingly, additional controls on EGUs may not be a reasonably available control measure that can be effectively implemented in a manner that advances an area's attainment date.

Comment: The EPA designated many partial counties nonattainment for $PM_{2.5}$ solely because the areas contained EGU emission sources thought to cause or contribute to violations of the NAAQS. In implementing attainment plans, it makes sense to consider further control of these sources, and because they are located in nonattainment areas, the ability to do so is provided for and legal under the CAA.

Response: The EPA designated $PM_{2.5}$ nonattainment counties because they either had a violating monitor or they contributed to a nearby air quality problem. Importantly, EPA designated these areas without considering the air quality benefits expected in the future from CAIR. Accordingly, the fact that an EGU is located in a partial county and we included the partial county in the nonattainment area because we believe that the EGU was causing or contributing to the nonattainment violations, does not equate with a finding that more than CAIR is required to remedy the nonattainment problem. Nonetheless, EPA believes that States should evaluate the impact of stationary sources in all designated counties, including those partial counties noted by the commenter, in its assessment of reasonably available control strategies to ensure attainment as expeditiously as practicable.

Comment: The EPA should adopt the Ozone Transport Commission's (OTC's) approach to cap-and-trade programs. When the OTC developed its NO_X

[41] See the regulatory impact analysis chapter on air quality for the 2006 PM NAAQS review at *http://www.epa.gov/ttn/ecas/regdata/RIAs/Chapter%204-Air%20Quality.pdf*.

Budget Program (which was the basis for EPA's NO_X SIP call and subsequently CAIR), it assumed that RACT was applied first. Thus the cap-and-trade program operated in an environment that assumed RACT was in force, not in lieu of RACT.

Response: Under the ozone national ambient air quality standards, NO_X and VOC RACT have been implemented progressively for the past 30 years or more, prior to development of the NO_X SIP call regional control program. In contrast, the $PM_{2.5}$ implementation program is the first instance in which we have required RACT/RACM specifically for fine particle pollution. For this reason, the CAIR program is not operating with SO_2 and NO_X RACT limits already in place for attainment of the $PM_{2.5}$ standards. Nonetheless, as discussed above, EPA believes that implementation of the CAIR requirements will provide for substantial progress in attaining the $PM_{2.5}$ standards and that States may presume that RACT/RACM requirements are equal to the CAIR level of control.

Comment: A few commenters stated that EPA should clarify and modify the part of its proposal that explains why a State cannot rely on EPA's determination that CAIR can satisfy the NO_X RACT requirement for $PM_{2.5}$ if the State ''elect[s] to allow non-EGU sources to voluntarily enter the EPA-administered CAIR trading program through an opt-in provision in the CAIR model rule.'' (70 FR 66025 col. 3). These commenters believe that this part of the proposal might be construed to preclude States subject to both the NO_X SIP Call and included in the CAIR region for ozone from relying on the NO_X RACT determination for $PM_{2.5}$ if the States choose ''to bring their non-CAIR [including non-EGU] NO_X SIP Call trading sources into the CAIR ozone season NO_X cap and trade program.'' (70 FR 49708, 49728 col. 3) (August 24, 2005). The commenters assert that EPA gave States the option of bringing non-EGU NO_X SIP Call sources into the CAIR seasonal NO_X trading program to ensure that non-CAIR sources, including non-EGUs, that are subject to the NO_X SIP Call rule would not be ''stranded,'' starting in 2009, by being left in an ozone season NO_X control program with no EGU trading partners. The commenters argued that ''EGUs should not be penalized, in the form of denial of CAIR–RACT treatment, as a result of States exercising their option to avoid financial and compliance difficulties for non-EGUs that otherwise would be left without allowance trading partners in the EGU sector after the NO_X SIP Call trading program ends in 2008.'' These commenters point to EPA's determination in the final Phase 2 ozone implementation rule, that participation in the CAIR trading programs can satisfy NO_X RACT for ozone even if a State brings non-EGUs in the NO_X SIP Call trading program into the trading program after 2008, *see* 70 FR 71657 col. 2, provided the State retains an ''EGU [emission] budget under CAIR that is at least as restrictive as the EGU budget that was set in the State's NO_X SIP call SIP,'' id. At 71658 col. 1. These commenters argue that EPA should make a similar determination here regarding NO_X RACT for purposes of $PM_{2.5}$ NAAQS implementation.

Response: All states with EPA approved CAIR SIPs or subject to a CAIR FIP implementing the annual NO_X emission reduction requirements, and obtaining those reductions solely from EGUs may rely on EPA's determination that CAIR presumptively satisfies NO_X RACT/RACM for $PM_{2.5}$ for these sources. This determination is unaffected by whether or not a State permits NO_X SIP Call non-EGUs to participate in the CAIR ozone season trading program. In the final rule, we have included the presumption that NO_X RACT/RACM for $PM_{2.5}$ is satisfied for EGUs complying with a CAIR SIP or CAIR FIP implementing the annual CAIR NO_X emission reduction requirements (provided the State implementation of the CAIR NO_X annual trading program includes EGUs only).[42]

In the final ozone implementation rule, EPA addressed numerous issues relating to the transition from the NO_X SIP Call to the CAIR ozone season trading program, including the impact of bringing NO_X SIP Call non-EGUs into the CAIR ozone season trading program. Commenters' suggestion that these determinations are relevant to this $PM_{2.5}$ implementation rule ignores the fact that both the NO_X SIP Call and the CAIR ozone season trading program are seasonal, not annual, trading programs. The NO_X SIP Call EGU and non-EGU budgets are seasonal NO_X budgets and do not address annual NO_X emissions. As discussed above, $PM_{2.5}$ levels year-round contribute to an area's annual average concentration, and NO_X emissions during non-summer months contribute to nitrate concentrations, which are typically highest in cooler temperatures. For these reasons, EPA believes it would be inappropriate to accept commenters' suggestion.

8. What Are the Required Dates for Submission and Implementation of RACT?

a. Background

The EPA requested comment on a general approach for the dates for submission and implementation of RACT rules. The final rule retains the proposed approach, as described in the following section.

b. Final Rule

The final rule requires the following:

(1) Date of submission. States must submit adopted RACT rules to EPA within 3 years of designation, at the same time as the attainment demonstration due in April 2008.

(2) Dates for implementation of control measures. States should also implement any measures determined to be RACT expeditiously, as required by section 172. Implementation of RACT measures should in no case start later than the beginning of the year before the nominal attainment date. For example, if an area has an attainment date of April 2010, then any required RACT measures should be in place and operating no later than the beginning of 2009. This is intended to help provide for clean air in calendar year 2009. As discussed in section II.D, if other criteria are also met, EPA could then grant the area a 1-year attainment date extension if the air quality level in the 3rd of the 3 years was below the level of the standard. If the area observes a second year of clean air, EPA could grant a second 1-year attainment date extension. In this case, the 2009 to 2011 period would then be reviewed to assess whether the area attains the standards.

(3) Provisions for a demonstration that additional time is needed. While EPA expects that States will implement required RACT controls by January 2009 in most situations, there may be cases where additional time is needed to implement an innovative control measure or to achieve a greater level of reduction through a phased approach. If a State has provided an adequate demonstration showing that an attainment date extension would be appropriate for an area, then the State may consider phasing-in certain RACT controls after January 2009. The EPA would allow the implementation of selected RACT controls after January 2009 if the State can show why additional time is needed for

[42] EPA's CAIR–RACT presumption also would not apply if a State required sources other than EGUs to achieve a portion of the reductions required by CAIR (e.g., the State's CAIR SIP achieved some reductions from EGUs but took credit for non-EGU reductions achieved under new, more stringent requirements implemented to meet NO_X SIP call caps). Under the CAIR rule such a State would not be eligible to participate in the EPA-administered CAIR trading system.

implementation, and such delayed implementation still would need to be on a schedule that provides for expeditious attainment. In no event could the State wait to implement RACT controls until the last few years prior to the attainment date without an adequate rationale for why earlier implementation was not feasible.

c. Comments and Responses

Comment: One commenter supported EPA's position that implementation of RACT and RACM by January 1, 2009 is necessary to achieve the effect on air quality for calendar year 2009.

Response: The EPA agrees with this comment.

Comment: Some commenters supported allowing for an implementation schedule that allowed for implementation of RACT and RACM for a time frame extending beyond 2009. These commenters favored such an approach if States provided an adequate demonstration of why the measures cannot be implemented earlier. Commenters noted that a phased approach to emissions reductions in some cases could lead to additional reductions that could not occur by 2009.

Response: The EPA agrees with these comments.

Comment: One commenter believed that so long as a State demonstrates attainment by 2015, EPA should not require implementation of any RACT measures. The commenter further asserted that it would be bad policy to require costly emissions reductions through imposition of RACT on areas expected to attain the standards through other means by 2015.

Response: The EPA disagrees with this comment. The CAA requires States to demonstrate that the attainment plan will attain the standards as expeditiously as practicable and must include RACT and RACM. The requirement for ''reasonable'' measures does not require that any theoretical measure be implemented, but does require implementation of those reasonable measures which could advance the attainment date by at least 1 year. Given the health effects associated with $PM_{2.5}$, EPA believes this approach is sound public policy.

9. Which Pollutants Must Be Addressed by States in Establishing RACT and RACM Limits in Their $PM_{2.5}$ Attainment Plans?

a. Background

In the proposed rule, and in the final rule as discussed in detail in section II.A above, EPA discusses the pollutants which States must address in the attainment plans, in particular with respect to RACT, RACM and NSR. These pollutants include not only direct $PM_{2.5}$, but also gaseous precursors to the formation of $PM_{2.5}$. In general, the decisions that States and EPA make with respect to which precursors are significant contributors to an area's $PM_{2.5}$ nonattainment problem define the pollutants and sources to be addressed by States in developing RACT and RACM.

b. Final Rule

In the final rule, in establishing RACT and RACM limits, those RACT and RACM limits must address:

—Direct emissions of $PM_{2.5}$
—SO_2, a precursor to $PM_{2.5}$ formation, and
—NO_X, unless a State makes a finding that NO_X emissions from sources in the State do not significantly contribute to the $PM_{2.5}$ problem in a given nonattainment area.

The EPA generally presumes that RACT and RACM limits are not needed for ammonia or VOC unless that State or EPA determines otherwise for a given nonattainment area. RACT and RACM limits are needed for ammonia if a State or EPA makes a finding that ammonia emissions significantly contribute to the $PM_{2.5}$ problem in a given nonattainment area, and thus finds that control of ammonia would help address the $PM_{2.5}$ problem. RACT and RACM limits are needed for VOC only if a State or EPA makes a finding that VOC emissions significantly contribute to the $PM_{2.5}$ problem in a given nonattainment area. (As a point of clarification, ''VOCs,'' which are gaseous organic precursors to the chemical formation of secondary organic aerosol, are treated differently from semivolatile or nonvolatile organic compounds which are addressed as directly emitted $PM_{2.5}$). Issues related to the finding of ''significant contribution'' for these pollutants are discussed in Section II.A above.

10. Under the $PM_{2.5}$ Implementation Program, When Does a State Need To Conduct a RACT Determination for an Applicable Source That Already Has a RACT, BACT, LAER, or MACT Determination in Effect?

a. Background

For $PM_{2.5}$ nonattainment areas, States are required to implement the RACT requirement to reduce emissions of direct $PM_{2.5}$ and $PM_{2.5}$ precursors from applicable sources. The EPA anticipates that for some sources located in $PM_{2.5}$ nonattainment areas, the State would have previously conducted RACT determinations for VOC or NO_X under the 1-hour ozone standard, or for direct PM_{10} emissions under the PM_{10} standards. Some of the RACT determinations established under these other programs would be relatively recent while other determinations may be more than 10 years old. In some cases, a new RACT determination might reach the conclusion that the preexisting determination is still valid and would require the installation of similar control technology because the relevant pollutant was addressed, the same emission points were reviewed, and the same fundamental control techniques would still have similar costs. In other cases, however, a new RACT analysis could determine, for example, that better technology has become available, and that cost-effective emission reductions are achievable.

In the proposed rule, the EPA requested comments on a general approach to taking prior RACT determinations into account, and within the general approach, invited comments on two specific questions: (1) Should new RACT determinations be required for all existing determinations that are older than a specified amount of time (such as 10 years old)?; and (2) what supporting information should a State be required to submit as part of its certification to demonstrate that a previous RACT analysis meets the RACT requirement currently for purposes of the $PM_{2.5}$ program?

In the proposed rule, EPA also noted that sources subject to RACT may also have been subject to other prior technology determinations such as BACT, LAER or MACT determinations. The proposed rule requested comment on approaches to taking these prior technology determinations into account.

b. Final Rule

The EPA has determined that it is appropriate to follow the approach in the proposed rule, which is described below. State RACT SIPs for $PM_{2.5}$ must assure that RACT is met, either through a new RACT determination or a certification that previously required RACT controls represent RACT for $PM_{2.5}$.

Where a State adopted and EPA approved a control measure as RACT for a pollutant emitted from a specific stationary source or source category under another NAAQS program, the State may submit as part of its SIP revision a certification, with appropriate supporting information, that the previous determination represents a current RACT level of control for those emissions for purposes of the $PM_{2.5}$ program. Otherwise, the State should revise the SIP to reflect a modified

RACT requirement for specific sources or source categories.

In cases where the State's prior RACT analysis under another NAAQS program concluded that no additional controls were necessary, a new RACT determination is required for that source. In cases where the previous RACT determination did not require any controls on the source, it is more likely that a new review might find that emission controls are now economically and technically feasible. This is because emissions reductions from a potential control measure are likely to be greater, and the cost per ton of emission reduction is likely to be lower, than in the case of a source that previously installed controls to meet RACT under another program.

A RACT determination for a source or source category subject to a prior RACT determination is also required for any pollutants that were not the subject of the prior RACT determination, but which the State has determined should be regulated for purposes of $PM_{2.5}$. The EPA advises that the State should closely review any existing RACT determinations established under another NAAQS program. For RACT certifications and determinations, States are to consider new information that has become available since the earlier RACT determination. For example, where updated information on control technologies is presented as part of notice-and-comment rulemaking, including a RACT SIP submittal for sources previously controlled, States (and EPA) must consider the additional information as part of that rulemaking. Existing EPA guidance on control technologies can be used to help inform RACT decisions. However, EPA believes it may not be sufficient for a State to rely on technology guidance that is several years old and issued to provide recommendations on control measures and levels for a different NAAQS in evaluating RACT for $PM_{2.5}$.

With respect to prior technology determinations other than RACT, the final rule provides that:

(1) Prior BACT and LAER Determinations. In many cases, but not all, best available retrofit technology (BACT) or lowest achievable emission rate (LAER) provisions for new sources would assure at least RACT level controls on such sources. The BACT/LAER analyses do not automatically ensure compliance with RACT since the regulated pollutant or source applicability may differ and the analyses may be conducted many years apart. States may, however, rely on information gathered from prior BACT or LAER analyses for the purposes of showing that a source has met RACT to the extent the information remains valid. We believe that the same logic holds true for emissions standards for municipal waste incinerators under CAA section 111(d) and NSR/PSD settlement agreements. Where the State is relying on these standards to represent a RACT level of control, the State should present its analysis with its determination during the SIP adoption process.

(2) Compliance With MACT Standards Affecting VOC. In situations where the State has determined VOC to be a significant contributor to $PM_{2.5}$ formation in an area, compliance with MACT standards may be considered in VOC RACT determinations. For VOC sources subject to MACT standards, States may streamline their RACT analysis by including a discussion of the MACT controls and relevant factors such as whether VOCs are well controlled under the relevant MACT air toxics standard, which units at the facility have MACT controls, and whether any major new developments in technologies or costs have occurred subsequent to establishment of the MACT standards. We believe that there are many VOC sources that are well controlled (e.g., through add-on controls or through substitution of non-VOC non-HAP materials for VOC HAP materials) because they are regulated by the MACT standards, which EPA developed under CAA section 112. Any source subject to MACT standards must meet a level that is as stringent as the best-controlled 12 percent of sources in the industry. Examples of these HAP sources that may effectively control VOC emissions include organic chemical plants subject to the hazardous organic NESHAP (HON), pharmaceutical production facilities, and petroleum refineries.[43] We believe that, in many cases, it will be unlikely that States will identify VOC emission controls more stringent than the MACT standards that are not prohibitively expensive and are thus unreasonable. We noted our view that this will allow States, in many cases, to conclude that the control measures implemented to meet MACT standards satisfy any requirement for VOC RACT.

(3) Compliance With MACT Standards Affecting $PM_{2.5}$ Emissions. Compliance with MACT standards may be considered in direct $PM_{2.5}$ RACT determinations. For direct $PM_{2.5}$ sources subject to MACT standards, States may streamline their RACT analysis by including a discussion of the MACT controls and relevant factors such as whether $PM_{2.5}$ emissions are well controlled under the relevant MACT air toxics standard, which units at the facility have MACT controls, and whether any major new developments in technologies or costs have occurred subsequent to the MACT standards. We believe that there are many direct $PM_{2.5}$ sources that are well controlled (e.g., through add-on controls that represent state-of-the-art measures for $PM_{2.5}$ reduction) because they are regulated by the MACT standards which EPA developed under CAA section 112. For some MACT standards, $PM_{2.5}$ is used as a surrogate for achieving MACT for HAPs such as heavy metals. Any source subject to MACT standards must meet a level that is as stringent as the best-controlled 12 percent of sources in the industry. We believe that there will be sources for which it will be unlikely that States will identify emission controls more stringent than the MACT standards that are not prohibitively expensive and are thus unreasonable. In addressing whether a MACT standard represents best controls for $PM_{2.5}$, it is important that the State consider all $PM_{2.5}$ sources at a given facility and the nature of the PM limit (i.e., whether the limit ensures control of the fine fraction of particulate matter). Also, the State should evaluate the degree of capture of $PM_{2.5}$—that is, the amount of $PM_{2.5}$ that is collected and sent to a pollution control device in addition to the efficiency of the device itself. This evaluation should consider the $PM_{2.5}$ emissions reductions that could be achieved by improving the degree of capture.

(4) Year-Round Controls for NO_X. In some cases, sources subject to NO_X RACT for PM will also be subject to controls under the NO_X SIP Call. In the 8-hour ozone implementation rule, EPA concluded that certain sources which have installed emission controls to comply with the NO_X SIP call would be deemed to meet NO_X RACT for the purposes of the 8-hour ozone implementation program. Some of these sources subject to the NO_X SIP call may choose to control NO_X emissions only or primarily during the ozone season. For purposes of $PM_{2.5}$, however, EPA concludes that the operation of emission controls only or primarily during the ozone season would not constitute RACT for $PM_{2.5}$ purposes. Indeed $PM_{2.5}$ control programs must address annual average concentrations, and in many

[43] There are some MACT categories for which it may not be possible to determine the degree of VOC reductions from the MACT standard without additional analysis; for example, the miscellaneous metal parts and products (40 CFR part 60, subpart MMMM) due to the uncertainty of the compliance method that will be selected.

areas nitrate concentrations are generally highest in the winter. Therefore, RACT for $PM_{2.5}$ is year-round operation of controls. For sources subject to both the NO_X SIP call and NO_X RACT for PM, we believe that, in most cases, the additional costs of running the NO_X SIP call controls year-round would impose only modest, reasonable additional costs and the cost effectiveness would be better than the average cost effectiveness for many other sources subject to PM RACT. (See further discussion in section F.7 above related to EGU sources subject to CAIR requirements for NO_X).

c. Comments and Responses

Comments: A number of commenters agreed with the requirement for the State to conduct a new RACT determination for any source for which the State's prior RACT analysis under another NAAQS program concluded that RACT was defined as no additional controls. One commenter noted that for a source having a previous RACT determination for ozone or PM_{10} to show that its level of control currently meets RACT for $PM_{2.5}$ purposes, the source must provide supporting documentation showing that the previous RACT determination was based on the same universe of controls that are ''reasonably available'' for the source in the present day.

Response: The EPA agrees with these comments.

Comments: A few commenters recommended that EPA clarify that RACT determinations resulting only in ''operational changes'' should be treated in an equivalent manner as those resulting in no controls. The commenters suggested that, unlike ''physical modification,'' such operational changes should always be revisited with a new RACT determination.

Response: The EPA does not agree with the implicit recommendation to impose different RACT review requirements based on the types of control previously implemented. The EPA believes that a reassessment of RACT is warranted, irrespective of the type of control previously implemented, to consider the reasonableness of modifying or adding controls in the particular circumstances. Furthermore, we are concerned that making such a distinction based upon the fairly broad term ''operational change'' would be difficult to interpret and implement, and would invite unnecessary disputes concerning the application of the term.

Comment: Commenters differed on whether new RACT determinations should be required for all existing determinations made before a specific date, and on what that date should be. Some commenters recommended that EPA allow States to rely on any previous RACT determinations made after 1990, and one commenter recommended that EPA require States to review only those older than 10–15 years, another recommended 10 years. One commenter believed that a 15-year period would be reasonable where previous controls were installed, to allow for a 15-year amortization of the cost of those controls. Other commenters recommended that new RACT determinations be made for any RACT determinations older than 5 years. Another commenter recommended that all RACT determinations should be reviewed.

Response: The EPA has not included any specific time frame in the final rule. The EPA agrees that the more recent the RACT determination, the greater the probability that technology advances or decreases in control cost will not have occurred. At the same time, technology advances and decreases in control cost can and have occurred frequently. Accordingly, we believe it is necessary for States to review whether such technology advances or decreases in control cost have occurred before relying on previous RACT determinations. We do not believe there is any specific date or age that could be identified after which States could ensure that no technology advances or decreases in control cost will have occurred.

Comment: A number of commenters expressed concerns with the resources required to conduct the certifications required by the proposed approach, and argued that expending the resources required to review and to certify previous RACT determinations would not be productive. One commenter recommended that EPA provide guidance on the previous RACT categories for which old RACT determinations are believed to be out of date. Another commenter asserted that the only possible exception to the acceptability of previous RACT measures for purposes of the ozone standards would be when the new RACT is year-round for an existing ozone-season RACT measure.

Response: The EPA believes that the proposed certification approach strikes an appropriate balance in requiring States to verify whether previous RACT determinations currently represent an appropriate RACT level of control for $PM_{2.5}$ purposes, while stopping short of requiring an exhaustive re-analysis for all RACT sources. The EPA believes that much of the resource concerns expressed in comments were based upon concerns that VOC sources are very numerous, and that this approach would require detailed review for these sources. As noted previously, a RACT analysis for VOC sources is required only if a State makes a finding that VOC sources significantly contribute to nonattainment in the State. We believe the commenters likely overestimate the resource implications of the certification process for prior RACT determinations. Another mitigating factor is that many of these same sources would be reviewed for purposes of implementing the eight-hour ozone standard. On the other hand, where a State or EPA determines that it is appropriate to regulate VOC sources for $PM_{2.5}$, EPA believes that it likely would be productive to review the previous determination for such sources, some of which have not been reviewed for many years.

Comment: One commenter believed that EPA should acknowledge detailed RACT and RACM analyses for the South Coast and San Joaquin Valley in California prepared during the 1990s for purposes of implementing the ozone and PM_{10} standards. The commenter believes that EPA acceptance of these determinations as RACT for $PM_{2.5}$ would enable States to focus resources on developing new measures needed for attainment.

Response: The EPA agrees that States should focus resources on new technologies and new developments. At the same time, EPA recognizes that for most source categories, new technology continues to be developed, and new information continues to be generated. Thus, even recent RACT determinations for a given source category may be outdated. Hence, the certification approach in the rule for the relevant sources or source categories is a reasonable approach which is designed to provide for the type of focused efforts suggested by the commenter.

Comment: One commenter believed that a State certification should only have to identify the existing RACT levels in a SIP and pollutants affected, but the State should not be required to provide any additional information.

Response: The EPA disagrees with this comment. The EPA believes that prior technology determinations should be taken into account in the RACT determination process. In reviewing existing RACT determinations, the State should provide supporting information to show that the existing technology in use should still be considered RACT, or it should show that there have been technology advances or cost reductions that have occurred since the previous

RACT limits were developed that make lower emissions technically and economically feasible in the context of RACT and would contribute to advancing the attainment date by at least one year.

Comment: Some commenters supported EPA's requirement for year-round operation of NO_X pollution control devices as RACT, given that $PM_{2.5}$ is an annual standard, while ozone is a summertime problem.

Response: The EPA agrees with these comments.

Comment: One commenter concluded that BACT and LAER determinations should be considered to satisfy RACT, regardless of the date they were made, because BACT and LAER by definition are more stringent than RACT.

Response: The EPA disagrees with this comment. The EPA believes that in many cases, but not all, BACT and LAER would assure RACT level of controls. Reasons that BACT and LAER might not satisfy RACT include: The pollutant of concern could have been different, the applicability threshold for BACT and LAER may have excluded smaller sources potentially subject to RACT controls, and technology advances or reductions in control costs may have occurred since the old determination was conducted.

Comment: One commenter recommended that EPA allow States to use information gathered from prior BACT or LAER analyses to complete the RACT determination, as was allowed in the 8-hour ozone NAAQS implementation rule.

Response: The final rule allows for use of such information, to the extent it remains valid, to inform a certification by the State that BACT or LAER technology continues to exceed what would currently be considered RACT.

Comment: Some commenters argued that any MACT determination that controls the pollutants of concern should be more than sufficient to satisfy RACT. Some commenters made similar recommendations regarding specific standards where PM limits were developed as a surrogate for HAPs, such as the MACT standard for integrated iron and steel mills, the MACT standard for iron and steel foundries, and the section 129 standards for waste to energy facilities.

Response: While agreeing that MACT controls are relevant, the EPA disagrees that all MACT determinations should be automatically considered to satisfy RACT. Reasons include: A MACT standard aimed at toxics might not ensure that the relevant $PM_{2.5}$ pollutant(s) are well controlled, MACT applicability provisions might have excluded units potentially subject to RACT, and technology advances or reductions in control costs might have occurred since EPA conducted the MACT analysis. The EPA believes that the State should review whether technology advances have occurred including available ''beyond the MACT floor'' technologies that may be reasonable in the context of RACT for $PM_{2.5}$ nonattainment, but which were not selected as MACT for purposes of implementing section 112. The EPA believes that RACT analyses should evaluate whether increased capture of $PM_{2.5}$ could be achieved, and whether an increased efficiency in controlling the fine fraction of particulate matter is reasonably available. The EPA has, however, added a specific recognition that MACT standards can reduce $PM_{2.5}$ as well as VOC, and that $PM_{2.5}$ information gathered for MACT standards development may inform a State's conclusions on available technologies for direct $PM_{2.5}$ emissions.

Comment: One commenter expressed a concern that EPA should not presume that MACT represents RACT where the MACT rule allows for a risk-based exemption from the control technology requirement.

Response: The EPA agrees with this comment.

11. How Should Condensable Emissions Be Treated in RACT Determinations?

a. Background

Certain commercial or industrial activities involving high temperature processes (fuel combustion, metal processing, cooking operations, etc.) emit gaseous pollutants into the ambient air which rapidly condense into particle form. The constituents of these condensed particles include, but are not limited to, organic material, sulfuric acid, and metals. In general, condensable emissions are taken into account wherever possible in emission factors used to develop national emission inventories, and States are required under the consolidated emissions reporting rule (CERR) [44] to report condensable emissions in each inventory revision. Currently, some States have regulations requiring sources to quantify condensable emissions and to implement control measures for them, and others do not. In 1990, EPA promulgated Method 202 in Appendix M of 40 CFR Part 51 to quantify condensable particulate matter emissions. In the proposed rule, EPA discussed and requested comment on issues related to condensable emissions in RACT determinations.

In the proposed rule, we noted that EPA is in the process of developing detailed guidance on a new test method which quantifies and can be used to characterize the constituents of the $PM_{2.5}$ emissions including both the filterable and condensable portion of the emissions stream. We also noted that when a source implements either of these test methods addressing condensable emissions, the State will likely need to revise the source's emissions limit to account for those emissions that were previously unregulated. For the purposes of determining RACT applicability and establishing RACT emission limits, EPA indicated in the proposal that it intends to require the State to adopt the new test method once EPA issues its detailed guidance. This guidance would be for use by all sources within a $PM_{2.5}$ nonattainment area that are required to reduce emissions as part of the area's attainment strategy.

b. Final Rule

Issues and comments related to test method and emissions limit issues for direct $PM_{2.5}$ for RACT, including discussion of test methods for condensable $PM_{2.5}$, are discussed in section II.L.3 of this preamble. The EPA recognizes that in some cases condensable emissions are more difficult to control than filterable emissions. However, condensable emissions may be assumed to be almost entirely in the 2.5 micrometer range and smaller, so these emissions are inherently more significant for $PM_{2.5}$ than for prior particulate matter standards addressing larger particles. Therefore, EPA encourages States to consider the potential for reducing condensable emissions when evaluating potential measures for RACT.

12. What Criteria Should Be Met To Ensure Effective Regulations To Implement RACT and RACM?

a. Final Rule

After the State has identified a RACT or RACM measure for a particular nonattainment area, it must then implement that measure through a legally enforceable mechanism (e.g., a State rule approved into the SIP). The legally enforceable mechanism must meet four important criteria.

First, the baseline emissions from the source or group of sources and the future year projected emissions must be quantifiable so that the projected emissions reductions from the sources can be attributed to the specific

[44] The consolidated emissions reporting rule was published in the **Federal Register** on June 10, 2002, pages 39602–39616.

measures being implemented. It is important that the emissions from the source category in question are accurately represented in the baseline inventory so that emissions reductions are properly calculated. In particular, it is especially important to ensure that both the filterable and condensable components of $PM_{2.5}$ are accurately represented in the baseline since traditional Federal and State test methods have not included the condensable component of particulate matter emissions and have not required particle sizing of the filterable component.

Second, the control measures must be enforceable. This means that they must specify clear, unambiguous, and measurable requirements. When feasible, the measurable requirements for larger emitting facilities should include periodic source testing to establish the capability of such facilities to achieve the required emission level. Additionally, to verify the continued performance of the control measure, specific monitoring programs appropriate for the type of control measure employed and the level of emissions must be included to verify the continued performance of the control measure. The control measures and monitoring program must also have been adopted according to proper legal procedures.

Third, the measures must be replicable. This means that where a rule contains procedures for interpreting, changing, or determining compliance with the rule, the procedures are sufficiently specific and nonsubjective so that two independent entities applying the procedures would obtain the same result.

Fourth, the control measures must be accountable. This means, for example, that source-specific emission limits must be permanent and must reflect the assumptions used in the SIP demonstration. It also means that the SIP must establish requirements to track emission changes at sources and provide for corrective action if emissions reductions are not achieved according to the plan.

b. Comments and Responses

There were no comments on this section. The language above is very similar to the language in the proposal.

G. Reasonable Further Progress (RFP)

1. Background

Clean Air Act Section 172(c)(2) requires that plans for nonattainment areas ''shall require reasonable further progress,'' which as defined in Section 171(1) ''means such annual incremental reductions in emissions of the relevant air pollutant as are required by this part or may reasonably be required by the Administrator for the purpose of ensuring attainment of the applicable national ambient air quality standard by the applicable date.'' This section describes the requirements the Administrator is establishing for states to achieve reasonable further progress.

In general terms, the goal of these RFP requirements is for areas to achieve generally linear progress toward attainment. The RFP requirements were included in the Clean Air Act to assure steady progress toward attaining air quality standards, as opposed to deferring implementation of all measures until the end date by which the standard is to be attained.

2. Requirements for Areas With Attainment Dates of 2010 or Earlier

a. Background

In 40 CFR 51.1009(b)(1) of the proposed rule, EPA proposed that a State which submits an implementation plan that demonstrates that an area will achieve attainment by 2010 (i.e., achieves attainment level emissions during 2009) would not be required to submit a separate reasonable further progress plan for that area. In such cases, EPA proposed that the attainment demonstration would also be considered to demonstrate that the area is achieving RFP.

b. Final Rule

In the final rule, EPA is maintaining the approach described in the proposed rule. An area that demonstrates attainment by 2010 will be considered to have satisfied the RFP requirement and need not submit any additional material to satisfy the RFP requirement. The EPA will view the attainment demonstration as also demonstrating that the area is making reasonable further progress toward attainment.

c. Comments and Responses

Comment: A number of commenters supported EPA's view that a demonstration of attainment by 2010 would also demonstrate that the area is making reasonable further progress toward attainment.

Response: The EPA appreciates the support and is adopting the supported approach.

Comment: A set of commenters objects to EPA's proposal, arguing that EPA cannot waive RFP requirements for areas where the state purports to demonstrate attainment. These commenters believe that Subpart 4 of Part D requires milestones prior to 2009, and these commenters believe that even Subpart 1 requires a demonstration of interim progress that EPA cannot waive.

Response: In brief, EPA is not waiving the RFP requirements for any area. Instead, EPA is concluding that a demonstration of attainment by 2010 also serves to demonstrate achievement of RFP. If the state submittal purports to demonstrate attainment but does not adequately make this demonstration, then the submittal also would not demonstrate achievement of RFP. The nature of the RFP requirement would then depend on whether the remedied attainment demonstration provides for attainment by 2010. Finally, as discussed above, EPA believes that Subpart 4 requirements do not apply to $PM_{2.5}$ plans. More detailed discussion of this comment and EPA's response are provided in the response to comments document.

3. Requirements for Areas With Attainment Dates Beyond 2010

a. Background

The proposed rule required a State to submit an RFP plan along with its attainment demonstration and SIP due in April 2008 for any area for which the State demonstrates that 2011 or later is the most expeditious attainment date. EPA proposed that the 2008 RFP plan must provide adequate emission reductions by 2009[45] and, in some cases, by 2012. The plan must demonstrate that emissions will decline in a manner that represents generally linear progress from the 2002 baseline year to the attainment year.

b. Final Rule

The final rule requires a State to submit an RFP plan along with its attainment demonstration and SIP due in April 2008 for any area for which the State justifies an extension of the attainment date beyond 2010. The RFP plan must provide emission reductions such that emissions in 2009 represent generally linear progress from the 2002 baseline year to the attainment year. Where the State justifies an extension of the attainment deadline to 2014 or 2015, the state must additionally provide emission reductions such that emissions in 2012 represent generally linear progress from the 2002 baseline year to the attainment year.

[45] The RFP test uses inventories for the full year, e.g. the year of 2009 or the year of 2012. EPA does not specifically require that the relevant measures be implemented by the beginning of the year, but RFP inventories must reflect the fact that measures that are implemented later in the year have correspondingly less impact on the year's annual total emissions.

If the State demonstrates that attainment will occur by 2010 or earlier, EPA will consider the attainment demonstration to demonstrate achievement of reasonable further progress, and the State will not be required to submit an additional RFP plan for the area.

c. Comments and Responses

Comment: For areas that demonstrate attainment by 2015 without adopting additional measures, a commenter recommended that the attainment demonstration be viewed as also demonstrating that the area is achieving RFP. The commenter therefore recommended that the state not be required to submit an RFP plan for such an area.

Response: A submittal that demonstrates attainment at the latest allowable date and does not address interim air quality fails to show that the path to attainment will yield interim incremental air quality improvements. States have ample opportunity to adopt measures that would provide interim air quality improvement long before 2015. Indeed, as discussed elsewhere as part of the discussion of attainment dates, a submittal that only addresses 2015 would also fail the attainment demonstration requirement, insofar as it would not be addressing whether attainment is as expeditious as practicable, because the submittal would fail to assess whether attainment could be achieved earlier. Therefore, irrespective of whether additional measures are needed to attain by 2015, the Clean Air Act mandates assessing progress at reasonable interim dates as well as mandating attainment.

4. Generally Linear Progress and Associated Timeline

a. Background

The EPA proposed that states with areas needing an extension of the attainment deadline beyond 2010 would be required to submit a plan demonstrating that emissions would be sufficiently reduced by 2009 to achieve a generally linear incremental improvement in air quality. The notice of proposed rulemaking provided an example calculation for an area with a 2013 attainment date, i.e. an area that achieves attainment level emissions in 2012. (See section III.G.4.b.iv of the proposal, 70 FR 66013.) In this example, the 2009 emissions year represents 7/10 of the period extending from the baseline year of 2002 to the 2012 year of attainment level emissions. Therefore, for this example, EPA's proposed requirement would be for this area to achieve emission reductions by 2009 representing approximately 7/10 of the emission reductions needed to attain the standards. For states with areas needing the attainment deadline extended to 2014 or 2015, EPA proposed to require achievement of generally linear emission reductions at two RFP milestone years—the 2009 and 2012 emission years.

The EPA received several comments on various elements of its proposed approach. Several commenters objected to EPA's proposed requirement to achieve linear progress toward attainment, asserting that EPA cannot reasonably expect states to achieve a significant amount of progress within a short time after plan submittals are due. Some commenters recommended requiring a specific emission reduction percentage, similar to the rate of progress requirement for ozone. These comments are addressed below.

b. Final Rule

The EPA is requiring States with areas needing an extension of the attainment deadline to submit RFP plans. These plans must demonstrate that generally linear reductions in emissions will occur by 2009, i.e. that emissions in 2009 will be reduced to the extent represented by a generally linear progression from 2002 base year emissions to attainment-level emissions. For any area that needs an extension of the attainment deadline to 2014 or 2015, the State's RFP plan would also need to demonstrate that generally linear reductions will be achieved in the 2012 emissions year as well.

c. Comments and Responses

Comment: Several commenters objected to EPA's proposed requirement that states demonstrate linear progress toward attainment. For example, a commenter stated that a ''generally linear reduction process may not be practicable.'' A commenter stated that it ''agrees that areas should be able to take credit for reductions from 2002 forward, [but] EPA should allow for fewer reductions (as opposed to linear reductions) prior to 2008.''

A commenter noted that EPA's ''proposed approach ignores several important realities about PM NAAQS implementation. First, * * * [n]ot until SIP submittal in April 2008, some 6 years after the RFP baseline date, will any local measures be finally adopted and approved. Under [the example EPA provided in its proposed rulemaking], states will be required to play 'catch-up' by achieving 70 percent of the required reductions in 2009. * * * Second, the 'generally linear' approach ignores that EPA intends for states to rely in large part on mobile source reductions and reductions in NO_X and SO_2 from CAIR implementation to achieve attainment in many areas. These measures fail a 'generally linear' test since most of the reductions they provide will not be realized until after 2009.'' This commenter continues that the incremental reductions in emissions required in the Clean Air Act need not be equal increments, that the absence of a specific statutorily mandated increment (such as the 3 percent per year requirement for ozone) allows EPA to be more flexible and to rely more heavily on later reductions. The commenter also argues that EPA's proposal is more stringent than the ozone RFP requirement, insofar as the ozone RFP requirement provides for averaging over 3 years. Similar comments were submitted by other commenters.

Another commenter supported EPA's proposal. This commenter supported requiring demonstrations that areas achieve emission reductions that will yield incremental improvement in air quality on a path toward expeditious attainment.

Response: The EPA believes that the requirement for generally linear reductions is reasonable because it allows States to take credit for early reductions achieved due to federal, State, and local programs. We find that it appropriately implements the RFP requirement in the Clean Air Act. For these reasons, EPA is finalizing the requirement that RFP plans for areas needing an attainment deadline extension show generally linear progress in reducing emissions from the base year through the 2009 emissions year. EPA is also requiring that areas needing an attainment deadline extension to 2014 or 2015 (i.e. attainment level emissions projected to start in 2013 or 2014) show generally linear progress in reducing emissions through the 2012 emissions year.

The commenters objecting to the requirement for generally linear progress appear to be assuming that only minimal emission reductions can be expected before 2008, so that a requirement for generally linear progress would require plans submitted in 2008 to compensate by achieving unrealistically high levels of emission reductions. The EPA disagrees with this assumption.

In fact, substantial emission reductions have occurred in the past few years and can be expected to occur through the 2009 emissions year. The EPA has promulgated significant mobile source rules recently that will yield

substantial benefits in the coming years, and these benefits follow a series of prior rules that provide a steady progression of emission reductions as newer, cleaner vehicles replace older, dirtier vehicles. For utilities, significant NO_X reductions occurred in 2004 under the NO_X SIP call, and substantial SO_2 reductions are expected to occur under the CAIR trading program prior to 2010 due to incentives for early reductions and the banking of allowances.

The EPA has also promulgated many other regulations that will reduce particulate matter and particulate matter precursor emissions before as well as after 2009. States have also been implementing a variety of measures. With use of a 2002 baseline, the assessment of RFP allows credit for these measures. The following is a partial list of the measures that have been adopted and will contribute to achieving generally linear reductions:

- NO_X SIP Call.
- Tightened emission limits for new gasoline and diesel vehicles.
- Numerous regulations requiring Maximum Achievable Control Technology, including regulations for:

—Iron and steel plants, including coke plants
—Industrial boilers
—Cement plants
—Lime plants
—Primary aluminum plants

- Numerous consent decrees for refineries.
- Numerous consent decrees for power plants.
- The Clean Air Interstate Rule for utilities.
- Retrofitted controls on diesel vehicles, and related programs for reducing diesel vehicle emissions.
- Closures of coke plants and other facilities (and, from a national perspective, replacement with cleaner new facilities).

While different control measures require various timelines for implementation, EPA believes that many of the additional measures that states might adopt for attainment planning purposes can be implemented in a timely fashion for addressing RFP requirements. Thus, EPA believes that states can reasonably be expected to assure that the combination of existing measures and additional measures as necessary will provide for generally linear progress in reducing emissions. Furthermore, particularly with respect to the 2009 RFP milestone year, when EPA evaluates whether the emission levels in a state plan represent generally linear progress, EPA will consider the availability of measures that can be implemented by 2009.

It is difficult to compare the stringency of this RFP requirement to the RFP requirement for ozone. The RFP requirement for ozone measures one form of progress that occurs after 3 years, and the requirement for $PM_{2.5}$ measures a different form of progress that occurs after 7 years (and for some areas also after 10 years). That is, the ozone RFP requirement applies a fixed, universally applicable emission reduction percentage for one pollutant (VOC), whereas EPA is defining the $PM_{2.5}$ RFP requirement as an area-specific combination of emission reductions for multiple pollutants, defined on the basis of each area's attainment demonstration.

The EPA believes that the Clean Air Act mandates not merely eventual attainment by 2015 but also that states demonstrate that emissions are being incrementally reduced in earlier years. (As discussed elsewhere, states must also demonstrate attainment by earlier than 2015 if feasible.) The requirement for RFP reflects Congressional intent that areas make steady progress toward attainment in the years before attainment occurs, and states have ample opportunity to assure that reductions occur well before 2015.

Comment: A commenter observes that the $PM_{2.5}$ nonattainment areas in its state also violate the ozone standard. The commenter observes, ''[i]n setting plan requirements, U.S. EPA should choose options that best facilitate harmonization of fine particulate and ozone control programs. This includes using a fixed percentage of emission reductions per year for reasonable further progress (RFP). We recommend the ozone RFP metric of three percent annual emission reductions averaged over three years.'' Another commenter also supports a more prescriptive RFP requirement, and comments that ''As suggested by EPA, nonattainment areas must be required to achieve 'a fixed percentage reduction of the emissions of direct $PM_{2.5}$ and regulated $PM_{2.5}$ precursors and in specific milestone years' between the base year and the attainment year proposed in the attainment demonstration.'' A third commenter supported establishing a requirement for a fixed emission reduction percentage, set at ''no less than the 3 percent rate'' in Section 182, with the possibility of higher rates in areas with more severe air quality problems.

Other commenters prefer the approach that EPA proposed. For example one commenter states that it agrees with EPA's approach of using the attainment demonstration to define the parameters for determining what constitutes RFP, and the commenter supports the flexibility of EPA's proposed approach ''rather than requiring fixed linear percentage reductions.'' Regarding the proposed option to require 3 percent per year emission reductions for areas classified as serious, some commenters recommended against establishing classifications and a fixed emission reduction percentage for any area.

Response: Requiring a fixed annual emission reduction percentage would impose a ''one-size-fits-all'' approach to address a range of circumstances. Requiring a fixed annual emission reduction percentage would overstate the reductions needed to achieve timely attainment in some areas and would understate the reductions needed to achieve timely attainment in other areas. The EPA believes that defining the RFP requirement in terms of achieving generally linear progress toward the emission reductions needed for timely attainment assures that each area will achieve a steady rate of progress most appropriate for the area to achieve timely attainment.

The EPA recognizes that many areas are nonattainment for both $PM_{2.5}$ and ozone and that the control programs for the two pollutants are sufficiently intertwined that harmonization of planning for meeting requirements applicable to the two pollutants is important. However, because the statutory requirements set forth in section 182 do not apply to $PM_{2.5}$ RFP plans, EPA believes it is neither necessary nor appropriate to impose these requirements for $PM_{2.5}$. Indeed, given the multiple pollutants that contribute to $PM_{2.5}$ and the variations that exist in the nature and composition of $PM_{2.5}$ across the country, EPA believes that the $PM_{2.5}$ RFP requirements for generally linear reductions are better defined to reflect these variations and thus better targeted toward the emission reductions that in each area can be expected to lead toward timely attainment. Further, EPA believes that application of a different form of the RFP requirement does not cause conflicts in implementation planning for the two standards. For example, reductions of NO_X emissions will generally reduce concentrations of both ozone and $PM_{2.5}$, and NO_X emission reductions are creditable for meeting both the ozone and the $PM_{2.5}$ RFP requirements.

An important distinction between $PM_{2.5}$ and ozone is that fine particle formation is in general a more complex process, affected by both direct emissions and numerous precursor pollutants. The EPA does not believe

that RFP targets for $PM_{2.5}$ should be the same as those used for the ozone implementation program, nor should the same percentage reduction be used for all $PM_{2.5}$ related pollutants. Instead, EPA believes that RFP plans should reflect an appropriate combination of pollutant reductions that most effectively provides for attainment. Therefore, EPA has defined an RFP requirement in which target emission reductions are established in conjunction with the area's attainment plan.

5. Geographic Coverage of Emissions Sources

a. Background

$PM_{2.5}$ concentrations reflect a combination of impacts over a wide range of geographic scales. For some components of $PM_{2.5}$, observed concentrations typically arise predominantly from sources within the nonattainment area. For other components, $PM_{2.5}$ concentrations may be influenced by sources across a broad area extending outside the nonattainment area. The EPA's intent is to define the RFP requirement in terms of emissions reductions that can be expected to provide generally linear improvements in air quality in the nonattainment area. For this purpose, EPA continues to believe that RFP requirements for $PM_{2.5}$ are best defined such that states evaluate emissions of each pollutant throughout the area in which the emissions substantially influence $PM_{2.5}$ concentrations in the nonattainment area.

As described in the proposed rulemaking, EPA expects each area's attainment demonstration to identify many of the parameters used to define the emission reductions that would represent RFP. First, the attainment plan will identify the pollutants that are being reduced to achieve attainment. Second, the attainment plan will identify the amount of reduction of each pollutant and the date by which attainment can be achieved. This information suffices to calculate a baseline set of reductions to be achieved by 2009 to provide for RFP. Third, where a state chooses to achieve RFP by reducing some pollutants earlier than others, the attainment plan will provide the information needed to assess whether the intended set of reductions can be expected to provide a comparable level of air quality improvement. Fourth, if the State intends to include emissions sources located outside the nonattainment area in its RFP plan, the information necessary to justify inclusion of such sources will likely be found in the attainment plan.

The EPA's proposed rulemaking identified several expectations regarding regional versus local impacts. For directly emitted $PM_{2.5}$ (including organic and other carbonaceous particles as well as miscellaneous inorganic particles and including condensable particulate matter), EPA recognized that impacts are commonly localized, and that direct emissions of $PM_{2.5}$ outside the nonattainment area should not be included in the RFP plan. Conversely, EPA recognized the regional nature of secondarily-formed sulfate and nitrate, and proposed that states could justify inclusion in the RFP plan of SO_2 and NO_X emissions sources located within 200 kilometers of the nonattainment area.

The EPA recognizes that fine particles travel over long distances, and that distant emissions of SO_2 and NO_X emissions can influence a nonattainment area's air quality. At the same time, distant sources can be expected to have less impact than sources closer to the nonattainment area. EPA's procedures for assessing RFP rely on a general assumption that all the sources included in the assessment have a comparable impact per ton of emissions. For this reason, it would be inappropriate to include distant emission sources in the assessment. Indeed, limiting the consideration of SO_2 and NO_X emissions to a 200 kilometer range is intended to assure that only sources with comparable impacts are included in the assessment.

b. Final Policy

The policy for addressing direct $PM_{2.5}$ emissions in RFP plans remains unchanged from the proposal: only emissions from within the nonattainment area may be included. Conversely, for SO_2 and NO_X, EPA believes that states could be able to justify considering not only all emissions in the nonattainment area but also emissions within a distance that may be up to 200 kilometers from the nonattainment area. States may also be able to justify consideration of VOC and ammonia emissions outside the nonattainment area on a case-by-case basis. As we explain more fully below in responding to comments, in situations where the state demonstrates that VOCs are a significant contributor to $PM_{2.5}$ concentrations in the area, it may be appropriate to include VOC emission sources within a distance of up to 100 kilometers of the nonattainment area. Given the uncertainties regarding ammonia emission inventories and the effects of reducing ammonia, EPA is not establishing a policy on this issue with respect to ammonia. States that expect to regulate ammonia should consult with their regional offices to determine appropriate approaches for those areas. The justification for considering emissions outside the nonattainment area shall include justification of the state's recommended definition of the area used in the RFP plan for each pollutant.

The EPA received comments objecting to the possibility that RFP inventories for areas outside the nonattainment area could include selected sources expecting substantial emission reductions while excluding other nearby sources expecting emission increases. Based on its review of these comments, EPA is revising its approach for considering regional emissions. If the state justifies consideration of precursor emissions for an area outside the nonattainment area, EPA will expect state RFP assessments to reflect emissions changes from all sources in this area. The State cannot include only selected sources providing emission reductions in the analysis. The inventories for 2002, 2009, 2012 (where applicable) and the attainment year would all reflect the same source domain (i.e. the same set of sources except for the addition of any known new sources or removal of known, creditably and permanently shut down sources).

In cases where the state justifies consideration of emissions of specified precursors from outside the nonattainment area, the state must provide separate information regarding on-road mobile source emissions within the nonattainment area for transportation conformity purposes. The EPA's transportation conformity regulations (40 CFR Part 93.102(b)) only require conformity determinations in nonattainment and maintenance areas, and these regulations rely on SIP on-road motor vehicle emission budgets that address the designated boundary of the nonattainment area. For this reason, if the state addresses emissions outside the nonattainment area for a pertinent precursor (i.e. a precursor for which mobile sources are significant, as discussed in the May 6, 2005 transportation conformity rule on $PM_{2.5}$ precursors at 72 FR 24280), the on-road mobile source component of the RFP inventory will not satisfy the requirements for establishing a SIP budget for transportation conformity purposes.

In such a case, the state must supplement the RFP inventory with an

inventory of onroad mobile source emissions to be used to establish a motor vehicle emissions budget for transportation conformity purposes. This inventory must address on-road motor vehicle emissions that occur within the designated nonattainment area, must be provided for the same milestone year or years as the RFP demonstration (i.e. 2009 and 2012 as applicable), and must satisfy other applicable requirements of the transportation conformity regulations. So long as the state provides this separate emissions budget EPA believes that this approach will optimally address both the RFP and the transportation conformity provisions of the Act.

The EPA is restricting the geographic area for RFP assessments to include only areas within the state or states represented in the nonattainment area. For a single state nonattainment area, only emissions within that state would be considered, even if other states may be within 200 kilometers of the nonattainment area. For multi-state nonattainment areas, only regions within states represented in the nonattainment area shall be included in the RFP assessment. This restriction is intended to address commenters' concerns about the enforceability of emission reductions included in the RFP assessment and helps assure accountability for these reductions. This topic is discussed further in the discussion below about multi-state nonattainment areas.

The EPA is retaining the approach that RFP assessments may not include direct $PM_{2.5}$ emissions from sources outside the nonattainment area. If a State regulates VOC or ammonia emissions as part of its attainment strategy, the RFP plan must include emissions of these pollutants. In the event that a State technical demonstration indicates that emissions of VOC or ammonia from sources outside the nonattainment area contribute significantly to $PM_{2.5}$ concentrations in the nonattainment area, EPA will consider on a case-by-case basis whether it would be appropriate to include emissions from such sources in the RFP plan.

c. Comments and Responses

The EPA received numerous comments on its proposal regarding how regional versus local impacts would be addressed. Multiple commenters objected to EPA's proposal that states could consider sources reducing emissions but ignore neighboring sources increasing emissions. Other commenters recommended that EPA support granting credit for reductions of direct $PM_{2.5}$ emissions that occur outside nonattainment areas. A few commenters also recommended different treatment of selected pollutants.

Comment: Several commenters object to the methods by which EPA proposed to account for reductions outside the nonattainment area. According to a set of commenters, if indeed sources outside the nonattainment area contribute to nonattainment, ''then EPA cannot lawfully or rationally allow the state to claim RFP credit from a single source's reductions without including in the baseline emissions from all sources (mobile, area and stationary) within the same distance from the nonattainment area, and without calculating the impacts of increases and decreases in such emissions on RFP. Viewing reductions from a single 'outside the area' source in isolation will invariably provide an incomplete and inaccurate picture of the actual increase or decrease in emissions contribution to the nonattainment area from all 'outside the area' sources. Moreover, EPA's proposal creates numerous opportunities to game and undermine the system. By allowing nonattainment areas to rely on RFP reductions made outside the nonattainment area, the proposed rule strays from the Act's focus on achieving emissions reductions from sources within the nonattainment area.'' Another commenter insisted that states should not be allowed to consider emissions from sources outside the area unless they can demonstrate the impacts of these sources on nonattainment area concentrations.

In addition, a commenter objects to consideration only of sources that are reducing emissions and recommends that EPA allow credit for upwind source reductions only ''on the condition that all other major sources in the 200 kilometer boundary are also not allowed to increase emissions.'' Another commenter supports an option which states would only consider emissions within the nonattainment area, observing that to consider emissions outside the nonattainment area would be difficult to administer and might inappropriately ''dilute the reductions needed in the nonattainment area.'' This commenter also observes that a 200 kilometer limit does not include much of the emissions that yield long range transport. Another commenter supports crediting reductions outside the nonattainment area but requests that EPA define the area to be considered.

Response: The EPA agrees that examining emissions reductions of only selected sources outside the nonattainment area gives an inaccurate assessment of the progress that an area is making. For example, if a state took credit for emission reductions at Source A but ignored equal emission increases at neighboring Source B, the state would claim emission reductions in its RFP plan when in fact no net emission reductions had occurred.

The commenters suggest various remedies for this problem. One suggestion is to include all sources within the area that is used. Another suggestion is to allow no consideration of emissions outside the nonattainment area. Yet another suggestion is to allow consideration of selected sources so long as other sources do not increase emissions.

The EPA is adopting the first of these suggestions: for the pertinent area outside the nonattainment area, the RFP assessment must include emissions (for all years evaluated) for all sources. The EPA believes that inclusion of all sources is needed to ensure that the RFP plan reflects the actual net emissions changes that are occurring in the relevant area.

In cases where the state justifies consideration of emissions of specified precursors from outside the nonattainment area, EPA is accepting the recommendation of various commenters that the inventories of these precursors used for RFP purposes shall include mobile source emissions as well as stationary and area source emissions. However, in cases where onroad mobile source emissions are significant and are therefore included, the state would need to submit additional information for transportation conformity purposes. As discussed above, in accordance with existing transportation conformity regulations (40 CFR Part 93), the SIP's motor vehicle emissions budget(s) must reflect an emissions inventory of on-road mobile source emissions for the nonattainment area. Consequently, in these cases, the state would need to supplement its RFP inventory with information identifying the inventory of on-road mobile source emissions within the nonattainment area for the pertinent precursor(s) for the applicable year or years (i.e. 2009 and potentially 2012) to be used to establish a motor vehicle emissions budget for transportation conformity purposes.

The relevant comments in general did not address the dimensions of spatial domain of the sources outside the nonattainment area that would be used in assessing RFP. EPA agrees with a commenter urging, as a prerequisite to including sources of the pertinent pollutants outside the nonattainment

area in the assessment, that states must justify the inclusion of sources outside the nonattainment area. This justification would need to demonstrate that these emissions have a substantial impact on nonattainment concentrations that warrants including these emissions along with nonattainment area emissions in assessing RFP. Another commenter recommends that EPA define the area to be included. Since the demonstrations of impact are best done by states, in conjunction with their attainment planning, EPA intends to allow States to justify the area to be included, within distance limits discussed above.

Comment: Numerous commenters recommend that EPA allow credit for reductions of direct $PM_{2.5}$ emissions outside the nonattainment area. Some of these commenters also recommend that EPA allow credit for mobile source emission reductions outside the nonattainment area. Other commenters support EPA's proposed approach, in which states may justify considering precursor emissions outside the nonattainment area but must evaluate direct $PM_{2.5}$ emissions based solely on emissions within the nonattainment area.

Response: Under Section 107 of the Clean Air Act, EPA is to designate nonattainment areas that include areas nearby to the violations that contribute to the violations. Given the spatial scale of the impacts of direct $PM_{2.5}$ emissions, EPA believes that any direct $PM_{2.5}$ emission source that demonstrably influences nonattainment area violations (and thus would contribute to these violations) would also be considered to be nearby to the violations for designation purposes. The EPA believes that it has properly defined the nonattainment areas to include all nearby contributing sources. Nevertheless, EPA asks anyone with evidence that an additional source or source area contributes to violations in a nonattainment area to submit that information to EPA and to recommend incorporation of that source or source area into the nonattainment area.

The EPA has commented on consideration of mobile source emissions above. For direct $PM_{2.5}$ emissions, EPA believes that the nonattainment area properly defines the area of consideration, and emissions from mobile sources outside the nonattainment area, like emissions from stationary sources outside the nonattainment area, should not be considered. For precursors for which consideration of emissions outside the nonattainment area is justified, the applicable inventories would include emissions from all sources including mobile sources as well as stationary sources.

Comment: A commenter states that ''RFP credits for VOC should be granted for reductions achieved within the nonattainment area as well as [within] geographical limits outside of the nonattainment area.'' This commenter supports consistency with the ozone policy, which allows credit for NO_X reductions within 200 kilometers and VOC reductions within 100 kilometers of the nonattainment area. Another commenter makes similar comments regarding VOC and comments that ''[a]s the science and understanding of $PM_{2.5}$ formation increases, EPA must revisit the 200 kilometer parameter and develop a possible proposal for ammonia.''

Response: Conceptually, EPA agrees that in areas where anthropogenic VOC emissions outside the nonattainment area are shown to be a significant contributor to nonattainment area $PM_{2.5}$ concentrations, presumably by formation of organic particles that influence nonattainment area concentrations, reduction of these VOC emissions could help improve air quality in the nonattainment area. Therefore, EPA is revising its policy to accommodate consideration of these potential impacts. The EPA believes that as the impacts of anthropogenic VOC on $PM_{2.5}$ concentrations are better understood, it may in some cases be appropriate to consider sources outside the nonattainment area in RFP plans if the impacts from such sources can be properly quantified and justified.

Nevertheless, EPA must highlight the technical challenges involved in assessing the impacts of VOC emission reductions. First, it is essential that the impacts of secondary organic particle formation from anthropogenic VOC emissions be differentiated from the impacts caused by biogenic VOC emissions and from the impacts of direct organic particle emissions. Second, the process of organic particle formation is highly complex, and currently available atmospheric models typically perform poorly in assessing the mass of particles thus formed. Third, the distance range of impacts, and to be more precise the distance range over which source impacts are comparable, is especially uncertain. While the distance range for organic particle formation is not necessarily the same as for the influence of VOC on ozone formation, it may be appropriate to include sources within 100 kilometers of the nonattainment area for both purposes, as the commenter recommended. However, any state wishing to include such sources outside the nonattainment area must justify the distance range that is appropriate for the area.

The EPA is not prepared at this time to establish generally applicable guidance with respect to how RFP plans should address ammonia in cases where that precursor is found to be significant. States that expect to regulate ammonia emissions should consult their regional office regarding appropriate approaches for their particular areas.

Finally, EPA agrees with the commenter that EPA should revisit the range of issues regarding geographic distances of impacts as more information and understanding become available.

6. Pollutants To Be Addressed in the RFP Plan

a. Background

A number of commenters appeared to be confused by the discussion in the notice of proposed rulemaking regarding the pollutants to be included in the RFP assessment. The EPA proposed that the attainment demonstration would provide the key parameters of the RFP demonstration, and that the list of pollutants to be addressed in the RFP demonstration would match the list of pollutants regulated as part of the attainment demonstration. However, the notice of proposed rulemaking also suggested that the presumptions regarding whether different pollutants are to be regulated under NSR and RACM (including RACT) would also apply to RFP. This led some commenters to recommend different treatment of specific pollutants.

In fact, the presumptions of applicability that EPA is promulgating for RACM are not germane to RFP. The pollutant coverage of RFP assessments is determined on an area-specific basis according to each area's attainment demonstration, and EPA need not establish presumptions as to what pollutants are included in the RFP assessment. For example, if a state includes no NO_X emission reductions in its attainment plan, then the RFP plan would not include NO_X, irrespective of whether the (uncontrolled) NO_X emissions contribute significantly to the areas $PM_{2.5}$ concentrations.

The contrast between establishment of presumptions for RACM and having no such presumptions for RFP (or for attainment demonstrations) reflects differences in regulatory context. For RACM, at issue is whether the impact of the pollutant is sufficient to warrant full implementation of the RACM requirements. In contrast, for RFP (as for attainment plans), EPA is establishing

an overall progress requirement that may be met by applying various control levels to various pollutants, so long as overall emission reductions are adequate. Indeed, if the state chooses not to control a particular pollutant in its attainment plan, then the presumption is that that pollutant would not be reduced in the RFP plan either. Furthermore, states have the flexibility to meet the overall progress with any adequate combination of control of relevant pollutants, regardless of the significance or insignificance of these pollutants' impacts. For these reasons, EPA is making no presumptions as to what pollutants will be included in RFP plans.

b. Final Policy

As proposed, the pollutants to be addressed in the RFP plan are those pollutants that are subject to control measures in the attainment plan.

c. Comments and Responses

Comment: A commenter states that ''VOC should be considered a presumptive $PM_{2.5}$ precursor.'' Another commenter recommends presuming that VOC and ammonia are included in the RFP plan.

Response: The EPA's approach to RFP does not rely on presumptions as to whether a pollutant does or does not warrant regulation as a precursor. Instead, pollutants are to be included or excluded according to whether the attainment demonstration includes emission controls for the pollutant that yield quantitative air quality benefits. Thus, irrespective of the presumptions applicable to RACM, the RFP plan would not include VOC unless the attainment plan reflects air quality improvements from VOC emission controls. The challenges of addressing VOC as part of an RFP plan were discussed earlier in this section. Similarly, ammonia would not be included in the RFP plan if the attainment plan does not regulate ammonia emissions.

7. Equivalent Air Quality Improvement

a. Background

The EPA proposed that states could use alternative combinations of various types of emission control programs to meet RFP requirements if the alternative would be expected provide air quality improvements that are approximately equivalent to those of the benchmark emission reductions. Some control programs for some pollutants can be implemented more quickly than other control programs. EPA believes that it is unnecessary to require that all pollutants be reduced at the same rate or by the same fraction of the ultimate attainment plan reductions. The EPA believes instead that the states should have flexibility to ''mix and match'' control strategies, so long as they provide a demonstration that the adopted approach can be expected to yield approximately the same air quality progress as an approach in which the state achieves an identical fraction of the attainment strategy for all pollutants by the RFP milestone date.

The notice of proposed rulemaking presented examples of the assessment of RFP, illustrating EPA's recommended approach for establishing a benchmark set of emission reductions and illustrating EPA's recommended procedures for whether modified approaches that control some pollutants earlier than other pollutants may be considered equivalent. While not repeated here, the examples remain appropriate for describing the approach included in the final rule. (See 70 FR 66012–66013).

Most commenters supported EPA's proposal to allow alternative combinations of control that can be shown by simple means to be equivalent. A set of commenters objected to this approach, given the uncertainties involved in the equivalency assessment. Nevertheless, for this aspect of RFP policy, EPA's final policy reflects the policy that it proposed.

b. Final Policy

The EPA is adopting an approach that establishes a benchmark level of controls but allows states the flexibility to adopt any combination of controls of the various pollutants that can be shown to provide equivalent benefits using procedures that EPA is recommending (or at the State's option, air quality modeling). The first step is to determine the ratio of the number of years from the baseline year to the RFP review year (e.g., the 7 years from 2002 to 2009) divided by the number of years from the baseline year to the year in which attainment level emissions are achieved (e.g. the 10 years from 2002 to 2012, for an area with a 2013 attainment deadline). The benchmark level of controls is then determined by multiplying this ratio times the level of control being achieved for each pollutant. For example, for an area with an attainment deadline extended to 2013, the benchmark level of controls would reflect 7/10 of the emission reductions of each pollutant that is controlled in the attainment plan.

The equivalency process involves consideration of the air quality benefits for the emission reductions in the alternative plan for each regulated pollutant. In effect, the air quality benefits for each pollutant are used as weighting factors, such that pollutants for which controls yield larger benefits are weighted more heavily in determining the adequacy of the resulting plan. For each pollutant, the first step is to find the ratio of the emission reductions achieved by the RFP milestone date (e.g. the emission reductions achieved between 2002 and 2009) divided by the emission reductions achieved by the attainment date. The second step is to multiply this ratio times the air quality improvement attributable to full implementation in the attainment year of the attainment strategy relevant to that pollutant. The third step is to add these pollutant-specific results to obtain a total estimated air quality benefit of the alternative plan.

The air quality benefits of the benchmark reductions are easier to determine. The first step, inherent to defining the benchmark reductions, is to determine the ratio of the number of years to the RFP review divided by the number of years to attainment level emissions (in the example above, 7/10). The second step is simply to multiply this ratio times the quantity of air quality improvement achieved by the attainment plan. (Conceptually, the calculations are the same as are done for the alternative plan, but the mathematics are simpler because one is applying the same assumed fraction of the attainment plan emission reductions (e.g. 7/10) for all pollutants, so that there is no need to subdivide by pollutant.) For each milestone date, any alternative that provides estimated air quality benefits by the RFP milestone date that at a minimum are generally equivalent to the estimated benefits of the benchmark level of emission reductions will be considered to satisfy RFP requirements.

c. Comments and Responses

Comment: A set of commenters argues that the equivalency process is too uncertain, and recommends instead that states be required to achieve at least a fixed percentage reduction for all pollutants. The commenters cite the uncertainties acknowledged by EPA, including potential nonlinearity (i.e. that a given percentage of an emission reduction may yield a different percentage of the related air quality benefit). The commenters contrast EPA's willingness to accommodate these uncertainties, for purposes of giving states flexibility for alternate RFP plan designs, with EPA's unwillingness to accommodate the uncertainties inherent

in regulating ammonia emissions. The commenters state that ''Rather than propose a standardized process for coherently determining 'equivalency,' EPA embraces the possibility that States will invent multiple and disparate methodologies.'' The commenters argue that the need for certainty in achieving emission reductions trumps the benefits of state flexibility, not the other way around. The commenters state that if ''EPA decides nonetheless to accept equivalency demonstrations, it should at least * * * require States to conduct dispersion modeling'' to confirm equivalency. The commenters further find unlawful the fact that EPA would allow ''rough equivalency'' rather than full equivalency to the benchmark approach. The commenters would prefer that EPA required a fixed percentage reduction of the emissions of direct $PM_{2.5}$ emissions and of each precursor.

Response: The EPA believes that its proposed approach satisfies the intent of the RFP requirement, which is to make ongoing, steady progress toward attainment rather than backloading control strategies. A requirement to obtain at least a given percentage of each of the pollutants that contribute to $PM_{2.5}$ concentrations would impose an inflexibility that EPA concludes is unnecessary where not required by the statute. The EPA proposed to require that areas achieve emission reductions that are generally linear, and a plan that provides for rough equivalency to the benchmark approach would indeed provide generally linear reductions. In response to commenters' requests for a standardized process for assessing equivalency, EPA believes the process outlined in the final rule is responsive to this request. It is not clear whether the fixed reduction percentage that certain commenters recommended would be an area-specific percentage (such as EPA uses to define the benchmark approach) or a universally applicable percentage (such as 3 percent per year). If the former, then EPA would repeat the response above regarding flexibility being consistent with the Act's requirements; if the latter, then responses in III.6.4 regarding a fixed reduction percentage apply. The EPA believes that the procedures it is establishing to assess equivalency are adequate for assessing RFP and that dispersion modeling need not be required for this purpose.

8. Other RFP Issues

a. Multi-State Nonattainment Areas

As stated in the proposed rulemaking, EPA seeks to ensure that nonattainment areas that include more than one State meet RFP requirements as a whole. Some commenters expressed concern about how one state's submittal should address emissions in other states, including how the state might address questions about the enforceability of another state's requirements.

The issues here resemble the issues for attainment demonstrations. In that context as well, EPA seeks plans that reflect active consultation by the affected states and provide a combination of reductions that are enforceable by the respective states that collectively provide for attainment. The active involvement of regional planning organizations helps assure a collective design of a plan with specific requirements to be adopted by specific states. Likewise for RFP, EPA would expect states with multi-state nonattainment areas to consult with other involved states, to formulate a list of the measures that they will adopt and the measures that the other state(s) will adopt, and then to adopt their list of measures under the assumption that the other state(s) will adopt their listed measures. That is, each state would be responsible for adopting and thereby providing for enforcement of its list of measures, and then that state and ultimately EPA (at such time as the plan is approved) would be responsible for assuring compliance with the SIP requirements.

In accordance with this view of RFP, as is the case for attainment plans, EPA expects states sharing a multi-state nonattainment area to submit a common assessment of whether RFP will occur. As a default, if the assessment only includes emissions within the nonattainment area, then each state would submit an assessment based on emissions from the full nonattainment area including portions of the area in other states. If the assessment includes precursor emissions from additional area outside the nonattainment area, then the states should have a common rationale for the area included, and all affected states would use the same inventory of the same multi-state area thus defined in assessing whether RFP will occur. The EPA would judge such submittals based on (1) whether the overall projected emission reductions will achieve RFP and (2) whether the submitting state has adopted the necessary enforceable measures to assure that the reductions projected within its boundaries will in fact occur.

As a point of clarification, even if a state justifies consideration of emissions outside the nonattainment area in its RFP assessment, EPA intends that these assessments not use emissions from outside the state or states represented in the nonattainment area. For single state nonattainment areas, only emissions within that state would be considered. This will help assure accountability for the emission reductions included in the plan.

b. Tribal Areas

The EPA received no comments on its proposed policy regarding RFP for tribal areas, and EPA is finalizing the proposed policy. Under its Tribal Authority Rule (40 CFR 49.4), EPA found that it was not appropriate to apply SIP schedule requirements to tribes. For similar reasons, EPA is not requiring tribes to submit RFP plans. Generally this exemption will have limited if any impact on the achievement of RFP by an area. Nevertheless, consistent with its general role in implementing programs for tribes where ''necessary and appropriate,'' EPA will work with the affected tribes and states to ensure that emissions on tribal lands are addressed appropriately. The EPA intends to ensure that areas that include both state and tribal lands will satisfy RFP on a collective basis, similar to the policy applicable to multi-state nonattainment areas.

9. Mid-Course Review

a. Background

The EPA proposed requiring mid-course reviews on a case-by-case basis. The proposal described a mid-course review as a combination of reviews aimed at assessing whether a nonattainment area is or is not making sufficient progress toward attainment of the $PM_{2.5}$ standards. The proposal described the mid-course review as involving ''three basic steps: (1) Demonstrate whether the appropriate emission limits and emission reduction programs that were approved as part of the original attainment demonstration and SIP submittal were adopted and implemented; (2) analyze available air quality, meteorology, emissions and modeling data and document relevant findings; and (3) document conclusions regarding whether progress toward attainment is being made using a weight of evidence determination.'' (Cf. 70 FR 66010)

The EPA views mid-course review requirements as part of a set of requirements for implementing the Clean Air Act requirements for reasonable further progress. For areas that demonstrate attainment by April 5, 2010, EPA believes that this attainment demonstration also demonstrates that reasonable further progress is being achieved. For areas that demonstrate

attainment after April 5, 2010, EPA is requiring states to submit an RFP plan, due on April 5, 2008, showing that emissions in 2009 and, in some cases, in 2012, will be sufficiently reduced to provide generally linear progress toward levels that are expected to yield attainment. At issue here is how then to conduct ongoing tracking of whether the planned progress toward attainment is in fact occurring. Subparts 2 (for ozone) and 4 (for PM_{10}) include explicit requirements for ongoing milestone tracking. Since Subpart 1 (applicable for $PM_{2.5}$) allows EPA flexibility in determining how ongoing progress is to be tracked, EPA may adopt other approaches for achieving the necessary assurances that ongoing progress toward attainment is occurring.

Milestone reviews can be confounded by changes in inventory methods (a concern expressed by a commenter particularly with respect to condensable emissions) and involve lengthy delays while inventories are compiled before planning can begin. Other approaches involving only air quality data reviews also do not provide for timely planning, insofar as such approaches involve waiting for three years of air quality data after implementation of controls before planning can begin. The EPA believes that a mid-course review provides the most productive approach, in lieu of establishing milestone tracking or other requirements, to assure that reasonable further progress in reducing emissions is being achieved. For this reason EPA proposed a requirement for mid-course reviews.

The EPA proposed a process for establishing and implementing mid-course review. After the state submits an attainment plan (due in April 2008), EPA would evaluate whether a mid-course review is warranted after considering various factors including factors identified in the proposal. The EPA did not propose to conduct further rulemaking on establishing this requirement, but EPA proposed that ''[w]here EPA finds that a MCR would be required, the approval of the [attainment] demonstration would be contingent on a commitment from the State to conduct the MCR.'' The mid-course review would then be due April 2010. The EPA's proposal also stated that ''EPA would determine [based on review of the mid-course review] whether additional emissions reductions are necessary,'' so that states would need to complete the mid-course review ''three or more years before the applicable attainment date to ensure that any additional controls that may be needed can be adopted [in timely fashion].'' Finally, EPA stated ''[i]f a mid-course review will be required for certain $PM_{2.5}$ nonattainment areas, separate $PM_{2.5}$ mid-course review guidance will be written to address the specific requirements of $PM_{2.5}$ nonattainment areas.''

The EPA received numerous comments objecting to EPA's proposed approach. Several commenters noted the inconsistency between requiring a mid-course review in April 2010 versus requiring a mid-course review due 3 or more years before an attainment date of 2012 or earlier. Multiple commenters objected to EPA requiring a mid-course review only 2 years after the initial attainment plan is due. A commenter requested ''nationally applicable guidance on when an MCR would be required and what it would need to include.'' No commenters supported EPA's timeline for mid-course reviews.

Based on the comments that EPA received, EPA has reevaluated the process for mid-course reviews. Upon reevaluation, EPA shares many of the concerns expressed by commenters about the proposal. The proposal indeed presents conflicting dates for submittal. The EPA agrees that a deadline just 2 years after the initial SIP submittal is too soon for states to conduct meaningful analyses of whether areas are making progress towards attainment. This problem would be exacerbated by the proposed process, in particular the fact that states would not know to begin work on a mid-course review until after they had submitted their initial SIP and after EPA had sufficiently reviewed the submittal to determine the need for a mid-course review. An early mid-course review also would defeat one of the purposes of the mid-course review, which is to take advantage of advances in the science and understanding of the nature of condensables and other components of $PM_{2.5}$, to adjust plans to be better targeted at solving problems. For these reasons, EPA is significantly revising its approach to mid-course reviews as recommended by the commenters. The EPA is establishing a rule which provides more certainty to the states as to applicability and content of mid-course review requirements, thereby avoiding the need for future EPA rulemakings on the subject. The EPA's rule clearly does not require states with early attainment dates to conduct a mid-course review and would clearly mandate a mid-course review only for areas with later attainment dates. The EPA's final rule clarifies the content of mid-course reviews and provides for states to make decisions on whether further controls are needed rather than having EPA make this determination. The mid-course review shall include an updated modeled attainment demonstration as well as a review of the implementation of measures in the April 2008 SIP and a review of recent air quality data. The EPA believes that all of these elements are necessary and should be sufficient for the state to identify whether additional measures are needed to achieve attainment by the attainment date in the approved plan. The EPA believes that states, not EPA, should make the initial determination as to whether additional measures are needed, and EPA has designed its mid-course review requirements to provide for the states to make this determination.

The EPA is promulgating a fixed date of April 2011 as a date for submittal of mid-course reviews for areas with attainment dates in 2014 or 2015. This fixed date will facilitate joint planning for multiple areas to apply common assumptions regarding regional transport. This date also gives states adequate notice for preparing these reviews and adequate time after the April 2008 submittal to incorporate new information and understanding of $PM_{2.5}$ nonattainment problems to adjust attainment strategies as appropriate.

The EPA is not requiring areas demonstrating attainment by 2013 or before to conduct a mid-course review. Such areas plan to have attainment level emissions by 2012, and EPA believes that an April 2011 mid-course review would not provide a timely reassessment of such areas' attainment plans. Instead, EPA is clarifying that mid-course reviews are only required for areas that demonstrate a need for an attainment date extension at least to April 2014.

b. Final Rule

For each area with an approved attainment date in 2014 or 2015, EPA is requiring the state to submit a mid-course review by April 2011. The mid-course review shall include an updated attainment demonstration as well as a review of the implementation status of measures included in the April 2008 submittal and a review of recent air quality data. The state shall determine whether additional measures are needed for timely attainment, just as the state is responsible for determining whether additional measures are needed in the April 2008 attainment demonstration, subject to formal EPA SIP review. The EPA is not requiring RFP milestone reviews, and EPA is requiring mid-course reviews for areas with sufficiently extended attainment dates in lieu of any other form of tracking reasonable progress.

c. Comments and Responses

Comment: A number of commenters objected to EPA's proposed timeframe that would have areas submit a mid-course review only 2 years after the initial SIP is due. They recommended, instead, that areas with attainment dates 2 years or more beyond the first 5-year period submit mid-course reviews 3 years after the SIPs are due (April 2011) and every 3 years thereafter, if necessary. Their reason for this suggestion is that the timing of mid-course review requirements needs to be clearer and should allow adequate time between plans and mid-course reviews if they are to serve as meaningful reviews.

Several commenters also noted an inconsistency in the timing of mid-course review requirements under EPA's proposal. The EPA proposed that mid-course review submittals would be due 5 years after the initial designation, which for all the original designations means 5 years after April 2005, i.e. April 2010. However, EPA also proposed that mid-course reviews would be due 3 years before the attainment date, which for areas with an April 2012 attainment date means April 2009. The commenters considered April 2009 for a mid-course review submittal to be too soon after the initial SIP submittal in April 2008, arguing that EPA would not have had time to review the 2008 SIP submittal, and the states would not have time to prepare a mid-course review by 2009. Some of these commenters expressed a view that EPA should not require mid-course reviews earlier than 3 years after the SIP submittal date.

Response: The EPA agrees with these comments. The EPA is remedying the inconsistency in submittal dates by establishing the single submittal due date of April 2011 that was recommended by the commenters. As requested by commenters, EPA is also clarifying the applicability of the mid-course review requirement. The requirement shall apply to areas with attainment dates of 2014 or 2015; mid-course reviews shall not be required for areas that are expected to attain the standards by 2013.

Comment: A commenter supports mid-course reviews as a means of assuring that areas with longer-term compliance dates are on track to attain the NAAQS as expeditiously as practicable.

Response: The EPA agrees that mid-course reviews can be a critical step in assuring expeditious attainment for areas with extended attainment dates. Indeed, EPA is relying on mid-course reviews rather than milestone reviews or other forms of RFP tracking to serve this purpose.

Comment: A commenter recommended eliminating mid-course review requirements for any area with less than seven years between SIP submittal and attainment. The commenter urged that EPA carefully reconsider its overall timelines for $PM_{2.5}$ while considering the feasibility and practical usefulness of the steps required of States and emission sources.

Response: The EPA agrees that the proposed timeline potentially required mid-course reviews in areas where such reviews would not be warranted, and the timeline did not provide the clarity as to the applicability of the requirement that states need to fulfill their planning responsibilities. In response, EPA is not requiring mid-course reviews for areas demonstrating attainment prior to 2014. For those areas that cannot demonstrate that attainment will occur prior to 2014, EPA has streamlined the mid-course review process so that the state bears responsibility for making the initial determination as to whether additional measures are needed to achieve timely attainment, rather than requiring additional steps of EPA rulemaking and initial findings by EPA as to the level of controls needed in the state's SIP. With the revised timetable, states can be assured of a meaningful mid-course review effort that focuses on the areas that particularly warrant such a review and for which time is available for a productive assessment of the need for additional measures.

Comment: One commenter stated that the proposal that allows the Agency to determine whether or not a State needs to submit a mid-course review with their attainment demonstration on a case-by-case basis lacks sufficient information. Since these attainment demonstrations must meet rigorous criteria, and require substantial work by the States, the commenter is concerned that the proposal neglects to outline the criteria EPA will use to make the case-by-case mid-course review determinations. The commenter asks that EPA provide the States with nationally applicable guidance on when an MCR would be required and what it would need to include.

Response: The EPA agrees with this comment. In particular, EPA agrees that establishing clear criteria for applicability and content of a mid-course review requirement will provide states the opportunity to plan for these reviews and conduct appropriate reviews in a timely fashion. Therefore, this final rule is establishing specific criteria for the applicability of the mid-course review requirement, namely that a mid-course review shall be conducted for any area that cannot demonstrate attainment before 2014. This final rule is also identifying the necessary elements of this mid-course review, i.e. a review of the implementation of measures in the 2008 SIP, and review of recent air quality data, and an updated modeled attainment demonstration.

H. Contingency Measures

a. Background

Under subpart 1 of the CAA, all $PM_{2.5}$ nonattainment areas must include in their SIPs contingency measures consistent with section 172(c)(9). Contingency measures are additional control measures to be implemented in the event that an area fails to meet RFP or fails to attain the standards by its attainment date. These contingency measures must be fully adopted rules or control measures that are ready to be implemented quickly upon failure to meet RFP or failure of the area to meet the standard by its attainment date. The preamble to the proposal stated that the SIP should contain trigger mechanisms for the contingency measures, specify a schedule for implementation, and indicate that the measures will be implemented without significant further action by the State or by EPA. The contingency measures should consist of other control measures for the area that are not included in the control strategy for the SIP.

The April 16, 1992 General Preamble provided the following guidance: ''States must show that their contingency measures can be implemented without further action on their part and with no additional rulemaking actions such as public hearings or legislative review. In general, EPA will expect all actions needed to affect full implementation of the measures to occur within 60 days after EPA notifies the State of its failure.'' (57 FR at 13512.) This could include Federal measures and local measures already scheduled for implementation, as explained below.

The EPA has approved numerous SIPs under this interpretation—i.e., that use as contingency measures one or more Federal or local measures that are in place and provide reductions that are in excess of the reductions required by the attainment demonstration or RFP plan. (62 FR 15844, April 3, 1997; 62 FR 66279, December 18, 1997; 66 FR 30811, June 8, 2001; 66 FR 586 and 66 FR 634, January 3, 2001.) The key is that the statute requires that contingency measures provide for additional emission reductions that are not relied

on for RFP or attainment and that are not included in the demonstration. The purpose is to provide a cushion while the plan is being revised to meet the missed milestone. In other words, contingency measures are intended to achieve reductions over and beyond those relied on in the attainment and RFP demonstrations. Nothing in the statute precludes a State from implementing such measures before they are triggered. In fact, a recent court ruling upheld contingency measures that were previously required and implemented where they were in excess of the attainment demonstration and RFP SIP. *See LEAN* v. *EPA*, 382 F.3d 575, 5th Circuit., 2004.

One basis EPA recommends for determining the level of reductions associated with contingency measures is the amount of actual $PM_{2.5}$ emissions reductions required by the control strategy for the SIP to attain the standards. The contingency measures are to be implemented in the event that the area does not meet RFP, or attain the standards by the attainment date, and should represent a portion of the actual emissions reductions necessary to bring about attainment in area. Therefore, the emissions reductions anticipated by the contingency measures should be equal to approximately 1 year's worth of emissions reductions necessary to achieve RFP for the area.

As stated previously, EPA believes that contingency measures should consist of other available control measures beyond those required to attain the standards, and may go beyond those measures considered to be RACM for the area. It is important, however, that States make decisions concerning contingency measures in conjunction with their determination of RACM for the area, and that all available measures needed in order to demonstrate attainment of the standards must be considered first; all remaining measures should then be considered as candidates for contingency measures. It is important not to allow contingency measures to counteract the development of an adequate control strategy demonstration.

The preamble to the proposal stated that contingency measures must be implemented without ''significant further action'' after EPA determines that the area has either failed to meet RFP, or has failed to attain the standard by its attainment date. The purpose of the contingency measure provision is to ensure that corrective measures are put in place automatically at the time that EPA makes its determination that an area has either failed to meet RFP or failed to meet the standard by its attainment date. The EPA is required to determine within 90 days after receiving a State's RFP demonstration, and within 6 months after the attainment date for an area, whether these requirements have been met. The consequences for states which fail to attain or to meet RFP are described in section 179 of the CAA.

2. Final Rule

The final rule includes regulatory text for contingency measures and maintains the overall policy approach as described in the preamble to the proposal. The key requirements associated with contingency measures are:

—Contingency measures must be fully adopted rules or control measures that are ready to be implemented quickly upon failure to meet RFP or failure of the area to meet the standard by its attainment date.

—The SIP should contain trigger mechanisms for the contingency measures, specify a schedule for implementation, and indicate that the measures will be implemented without further action by the State or by EPA.

—The contingency measures should consist of other control measures for the area that are not included in the control strategy for the SIP.

—The measures should provide for emission reductions equivalent to about 1 year of reductions needed for RFP, based on the overall level of reductions needed to demonstrate attainment divided by the number of years from the 2002 base year to the attainment year. Contingency measures are those measures that would not be included in the attainment strategy for various reasons; for example, they may not be as economically feasible as other measures that are considered to be RACM, or it may not be possible to implement the measures soon enough to advance the attainment date (e.g. federal mobile source measures based on the incremental turnover of the motor vehicle fleet each year).

3. Comments and Responses

Comment: Several comments were received concerning the requirement for contingency measures under section 172(c)(9). The proposal indicated that contingency measures adopted as part of the State plan are to be equal to approximately 1 year's worth of emissions reductions necessary to achieve RFP, as determined by the attainment demonstration for the area. One commenter indicates that this amount of reductions for contingency measures may be excessive in some cases. The commenter stated that States should be allowed to demonstrate appropriate amount of reductions for contingency measures in each area based on the degree of the $PM_{2.5}$ nonattainment area problem and the progression of emission reductions planned for the area as a part of the SIP.

Response: The EPA agrees that the CAA does not include the specific level of emission reductions that must be adopted to meet the contingency measures requirement under section 172(c)(9). One possible interpretation of the CAA would assume that contingency measures should be in place in the event that all of the State's measures fail to produce their expected emission reductions. Under this scenario, the State theoretically would be required to adopt sufficient contingency measures to make up for the entire short fall. In other words, the State would have to adopt ''double'' the measures required to satisfy the applicable emissions reduction requirements.

The EPA believes that this scenario would be highly unlikely and that this interpretation would be an unreasonable requirement. The adoption of double the measures needed for attainment would be difficult for States. Therefore, the EPA believes that it is reasonable that contingency measures should, at a minimum, ensure that an appropriate level of emissions reduction progress continues to be made if attainment or RFP is not achieved, or if an area fails to attain the standard by its statutory attainment date and additional planning is needed by the State. The EPA believes that the contingency measures adopted by the State for the affected area should represent a portion of the actual emissions reductions necessary to bring about attainment in the area. Therefore, EPA believes that it is reasonable to require states to adopt contingency measures equal to approximately 1 year's worth of emissions reductions necessary to achieve RFP for the area.

Comment: One commenter claimed that EPA incorrectly quoted the CAA as requiring SIPs to provide for implementation of contingency measures upon an attainment or RFP failure, without ''significant'' further action by the State or EPA. The commenter stated that section 172(c)(9) does not contain the word ''significant.'' The CAA requires that contingency measures take effect ''without further action'' by the State or EPA.

Response: The EPA agrees with the commenter that the general requirements for attainment plans specified under section 172(c)(9) State that each plan must contain additional measures that will take effect without

'further action' by the State or EPA if an area either fails to make RFP or fails to attain the standard by the applicable attainment date. Section 51.1012 of the final rule describes the contingency measures requirement and does not include the word ''significant.'' However, as a matter of practicality states need to take minimal steps to make contingency measures effective and alert the affected public that the measures are in force. Thus, EPA has indicated based on conclusions first made in the 1992 General Preamble that states should complete all of these administrative steps within 60 days and that all regulatory steps be completed before SIP submission.

Comment: The commenter further states that EPA is wrong in asserting that contingency measures can include Federal measures and local measures already scheduled for implementation, or previously implemented measures that provide 'excess' reductions. The CAA requires contingency measures to consist of controls 'to be undertaken if' the area fails to meet attainment or RFP. The commenter states that this language clearly states that such measures are to be new measures that will be undertaken upon the triggering event specifically to address RFP or failure to attain, not measures already in place, or measures required for other reasons.

Further, the commenter claims that EPA can not rationally refer to any reductions prior to an attainment or RFP failure as 'excess' when total reductions in the area in fact prove insufficient to meet attainment RFP. The commenter states that EPA cites a 5th Circuit case as support, but the commenter respectfully submits that the case was incorrectly decided on this issue for the aforementioned reasons.

Response: In response to comments claiming that EPA is wrong in asserting that contingency measures can include Federal measures and local measures already scheduled for implementation, or previously implemented measures that provide 'excess' reductions, as stated previously, the EPA has approved numerous SIPs under this interpretation. The statute requires that contingency measures provide for additional emission reductions that are not relied on for RFP or attainment and that are included in the attainment demonstration for the area. These measures are intended to provide a ''cushion'' in terms of emissions reductions for the area while the State is revising the SIP for the area due to the failure to show RFP or attain. In other words, contingency measures are intended to achieve reductions over and beyond those relied on in the attainment and RFP demonstrations. Nothing in the statute precludes a State from implementing such measures before they are triggered.

As noted above, EPA's General Preamble interpreted the control measure requirements of sections 172(c)(9) and 182(c)(9) to allow nonattainment areas to implement their contingency measures early. 57 FR 13498, 13511 (April 16, 1992). The EPA has applied this interpretation in rulemakings. See, for example, 67 FR 6,590, 6,591–92 (September 26, 2002). See also rulemakings cited in the Background section, above. As set forth above, the Fifth Circuit has upheld EPA's interpretation. *Louisiana Environmental Action Network* v. *EPA,* 382 F.3d 575 (Fifth Cir. 2004). (''*LEAN*'') Commenters have not provided a basis for concluding that the Fifth Circuit in the *LEAN* case wrongly interpreted the CAA.

Commenters contend that the language in the CAA regarding contingency measure controls ''to be undertaken'' requires measures not already in place or required for other reasons. The Fifth Circuit disagreed, finding that the terms in section 172(c)(9)—''to be undertaken'' and ''to take effect''—were ambiguous, and finding persuasive EPA's interpretation that this language allows measures already in place or otherwise required. The Court held:

> ''Here, the EPA's allowance of early reductions to be used as contingency measures comports with a primary purpose of the CAA—the aim of ensuring that nonattainment areas reach NAAQS compliance in an efficient manner—and necessary requirements of the CAA.'' 382 F.3d at 583.

The Court further found that ''By utilizing contingency measures early, the contingency measures ensured that 'an appropriate level of emissions reduction progress' would be implemented while the State 'adopt[ed] newly required measures resulting from the bump-up to a higher classification.'' [citing the General Preamble]. *Id.*

In addition, the Court agreed with EPA that ''early reductions are necessary in order to create an incentive for nonattainment areas to implement 'all reasonably available control measures as expeditiously as practicable' '' in accordance with section 172(c)(1) of the CAA. Thus the Court concluded that it would be ''illogical to penalize nonattainment areas that are taking extra steps, such as implementing contingency measures prior to a deadline, to comport with the CAA's mandate that such states achieve NAAQS compliance as 'expeditiously as practicable.' '' *Id.* at 583–584.

The Fifth Circuit also endorsed the concept of ''excess'' reductions, noting that the reductions credits at issue in that case, ''although already implemented, are in effect set aside, 'to be applied in the event that attainment is [not] achieved' and such reduction credits 'are not available for any other use.' [citations omitted]. The setting aside of a continuing, surplus emissions reduction fits neatly within the CAA's requirement that a necessary element of a contingency measure is that it must 'take effect without further action by the State or [EPA]'.'' The Court concluded that ''the early activation of continuing contingency measures is consistent with the purpose and requirements of the CAA statute.'' Id. at 584.

Thus, EPA's approval of early implemented contingency measures is consistent with the CAA, as well as with EPA guidance. For example, EPA has consistently taken the position that ozone nonattainment areas classified moderate and above must include sufficient contingency measures so that ''upon implementation of such measures, additional emissions reductions of up to 3 percent of the emissions in the adjusted base year inventory (or such lesser percentage that will cure the identified failure) would be achieved in the year following the year in which the failure has been identified.'' 57 FR at 13511 (EPA's General Preamble). Thus the contingency measures are supposed to ensure that progress towards attainment will occur while the relevant State adopts whatever additional controls may be necessary to correct a shortfall in emissions reductions. *Id.* The EPA has historically allowed early reductions—that is, reductions achieved before the contingency measure is ''triggered''—to be used as contingency measures. See also August 13, 1993 Memorandum from G.T. Helms: Early Implementation of Contingency Measures for Ozone and Carbon Monoxide (CO) Nonattainment Areas).

The commenter's argument that emission reductions cannot be valid contingency measures if they are otherwise required is also misplaced. A State must have the legal authority to require whatever reductions it may require as a contingency measure. As EPA has previously stated, ''all contingency measures must be fully adopted rules or measures.'' 62 FR 15844, 15846 (April 3, 1997). The fact that the State or Federal government has already exercised that authority is irrelevant because, as noted above, contingency measures must ''take effect

without further action by the State or [EPA].'' Section 172(c)(9). Thus, by definition, the State necessarily will have already exercised its legal authority to require reductions as a contingency measure before the measure is triggered. It does not matter whether or not a specific contingency measure is already required by law, as long as the emissions reductions that will result from that contingency measure have not been accounted for in the attainment and reasonable further progress demonstrations. If the reductions from the contingency measure are not available for any other use, then they are surplus that is set aside in the event reasonable further progress or attainment is not achieved.

A key element of a valid contingency measure reduction is that the State may not use the reduction in its attainment or reasonable further progress demonstrations if it is already using the reduction as a contingency measure. Those demonstrations must account for the actual emissions reductions that will make reasonable further progress towards, and achieve attainment of the NAAQS in the absence of contingency measures.

I. Transportation Conformity

Transportation conformity is required under CAA section 176(c) (42 U.S.C. 7506(c)) to ensure that Federally supported highway and transit project activities are consistent with (''conform to'') the purpose of the SIP. Conformity currently applies to areas that are designated nonattainment, and those redesignated to attainment after 1990 (''maintenance areas'' with plans developed under CAA section 175A) for the following transportation-related criteria pollutants: ozone, particulate matter ($PM_{2.5}$ and PM_{10}), carbon monoxide (CO), and nitrogen dioxide (NO_2). Conformity to the purpose of the SIP means that transportation activities will not cause new air quality violations, worsen existing violations, or delay timely attainment of the relevant NAAQS (or ''standards'').

The final $PM_{2.5}$ implementation rule does not contain any revisions to the transportation conformity regulation. The EPA addressed the transportation conformity requirements that apply in $PM_{2.5}$ nonattainment and maintenance areas in three separate rulemakings as described below.

First, on July 1, 2004, EPA published a final rule (69 FR 40004) that addressed the majority of requirements that apply in $PM_{2.5}$ areas including:

- Regional conformity tests to be used in conformity determinations both before and after SIPs are submitted and motor vehicle emissions budgets are found adequate or are approved;
- Consideration of direct $PM_{2.5}$ emissions in regional emissions analyses;
- Consideration of re-entrained road dust in $PM_{2.5}$ regional emissions analyses;
- Consideration of transportation construction-related fugitive dust in $PM_{2.5}$ regional emissions analyses; and
- Compliance with $PM_{2.5}$ SIP control measures.

Then on May 6, 2005, EPA promulgated a final rule (70 FR 24280) that specified the transportation-related $PM_{2.5}$ precursors and when they apply in transportation conformity determinations in $PM_{2.5}$ nonattainment and maintenance areas.

Finally, on March 10, 2006, EPA promulgated a final rule (71 FR 12468) that establishes the criteria for determining which transportation projects must be analyzed for local particle emissions impacts in $PM_{2.5}$ and PM_{10} nonattainment and maintenance areas. If required, an analysis of local particle emissions impacts is done as part of a transportation project's conformity determination.

Transportation conformity for the $PM_{2.5}$ standards began applying in $PM_{2.5}$ nonattainment areas on April 5, 2006, one year after the effective date of EPA's $PM_{2.5}$ nonattainment designations (i.e., April 5, 2005). CAA section 176(c)(6) and 40 CFR 93.102(d) provide a one-year grace period before conformity applies in areas newly designated nonattainment for a new standard. $PM_{2.5}$ SIP submissions such as RFP and attainment demonstrations would identify motor vehicle emissions budgets (''budgets'') for direct $PM_{2.5}$ or $PM_{2.5}$ precursors, as described below. These budgets would be used for satisfying transportation conformity requirements, once the budgets are found adequate or the SIP containing the budgets is approved by EPA. For example, state and local agencies would consider during the development of the $PM_{2.5}$ SIP whether reductions of on-road mobile source $S0_2$ emissions are a significant contributor to an area's $PM_{2.5}$ air quality problem, and if so, establish a $S0_2$ motor vehicle emissions budget for transportation conformity purposes.

The EPA has previously addressed its intentions regarding when budgets must be established in $PM_{2.5}$ SIPs for transportation conformity purposes. RFP plans, attainment demonstrations, and maintenance plans must include a budget for direct $PM_{2.5}$ emissions, except for certain cases as described below. All $PM_{2.5}$ SIP budgets would include directly emitted $PM_{2.5}$ motor vehicle emissions from tailpipe, brake wear, and tire wear. States should also consider whether re-entrained road dust or highway and transit construction dust are significant contributors and should be included in the $PM_{2.5}$ budget. For further information, see 40 CFR 93.102(b) and 93.122(f) of the transportation conformity regulation, as well as Sections VIII–X of the July 1, 2004 conformity rule preamble at 69 FR 40031–40036.

Under certain circumstances, directly emitted $PM_{2.5}$ from on-road mobile sources may be found an insignificant contributor to the air quality problem and NAAQS. Section 93.109(k) of the conformity rule states that ''[s]uch a finding would be based on a number of factors, including the percentage of motor vehicle emissions in the context of the total SIP inventory, the current state of air quality as determined by monitoring data for that NAAQS, the absence of SIP motor vehicle control measures, and historical trends and future projections of the growth of motor vehicle emissions.'' The EPA discussed its intentions for applying the insignificance provision in the July 2004 final rule (69 FR 40061–40063).

In the May 6, 2005 final rule, EPA provided details regarding when states must establish SIP budgets for any $PM_{2.5}$ precursor (i.e., NO_x, VOCs, $S0_2$ and ammonia). If through the SIP process a state concludes that on-road mobile source emissions of one or more precursors are significant (i.e. need to be addressed in order to attain the $PM_{2.5}$ standards as expeditiously as practicable), then EPA expects that the state will include a budget in the SIP for each of the relevant precursors. (70 FR 24287) The EPA also noted in the May 2005 conformity rule that, if inventory and modeling analyses demonstrating RFP, attainment or maintenance indicate a level of emissions of a precursor that must be maintained to demonstrate compliance with the applicable requirement, then that level of emissions should be clearly identified in the SIP as a budget for transportation conformity purposes, even if the SIP does not establish particular controls for the given precursor. If the state fails to identify such a level of emissions as a budget, EPA will find the submitted SIP budgets inadequate because the SIP fails to clearly identify the motor vehicle emissions budget as required by the conformity rule (40 CFR 93.118(e)(4)(iii)). (70 FR 24287) In determining whether the on-road mobile source emissions of a $PM_{2.5}$ precursor are significant, state and local agencies would use the criteria for insignificance findings provided in 40 CFR 93.109(k)

of the transportation conformity regulation. A further discussion of the criteria to be considered in establishing $PM_{2.5}$ precursor budgets is contained in the May 2005 final transportation conformity rule (70 FR 24282–24288). If state and local agencies conclude that on-road sources of a precursor are not a significant contributor to the area's $PM_{2.5}$ air quality problem, as described above, motor vehicle emissions budgets would not be established even though emissions may be addressed in the area's RFP plan, attainment demonstration and/or maintenance plan.

J. General Conformity

a. Background

The General Conformity regulations promulgated in 1993 establish an implementation process where Federal agencies are responsible for making their own determination of conformity with State implementation plans (SIPs), and EPA plays an advisory role. Recognizing that it was impracticable to evaluate all Federal actions for conformity, EPA created a number of exemptions in those regulations for actions with insignificant or not reasonably foreseeable emission increases, including exemptions for Federal actions with emissions below specified *de minimis* levels. When a Federal agency must demonstrate conformity for an action, the regulations provide several methods for making that demonstration. With the designations of $PM_{2.5}$ nonattainment areas on April 5, 2005, requirements for demonstrating conformity become effective in those areas on April 5, 2006.

On July 17, 2006 EPA issued a final rule (71 FR 40420) to amend the General Conformity Regulations to establish *de minimis* levels for $PM_{2.5}$ for the General Conformity program. The final rule established 100 tons/year of direct $PM_{2.5}$ emissions and its precursors as the *de minimis* level where the General Conformity regulations would apply in $PM_{2.5}$ nonattainment areas. In the process of finalizing the *de minimis* level for $PM_{2.5}$ three comments were received. One commenter was concerned about emissions from burning by Federal agencies. Another commenter proposed that the *de minimis* level for emissions of direct $PM_{2.5}$ should be set significantly lower than 100 tons—in the range of 25–50 tons per year (TPY) in areas that are likely to attain the $PM_{2.5}$ national ambient air quality standard within 5 years, and a level of 10–25 TPY in areas that are likely to take more than 5 years to achieve the national ambient air quality standard. A third commenter supported the proposed *de minimis* level.

The final rule revises the tables in sub-paragraphs (b)(1) and (b)(2) of the General Conformity Regulations by adding a *de minimis* emission level for $PM_{2.5}$ and its precursors. This action maintained our past policy of consistency between the conformity *de minimis* emission levels and the size of a major stationary source under the New Source Review program (70 FR 65984). These levels are also consistent with the levels promulgated for Reasonably Available Control Technology applicability levels for volatile organic compound and nitrogen oxide emissions in subpart 1 areas under the 8-hour ozone implementation strategy (68 FR 32843). Since EPA is not finalizing any classifications for the $PM_{2.5}$ nonattainment areas, we did not establish differing $PM_{2.5}$ *de minimis* emission levels for higher classified nonattainment areas.

b. Comments and Responses

Comment: One commenter requests that EPA communicate to all Federal agencies the value of the agencies advising the States as soon as possible of any planned future projects in nonattainment areas that may be above the General Conformity *de minimis* values or that will have to be evaluated to show that they are below *de minimis*. This is for projects that are very likely to proceed. The aim is to consider these future emissions in any growth projections during SIP development since such growth may not be anticipated well by the available growth model (E–GAS). States can communicate with existing Federal facilities now concerning this issue.

Response: The EPA sees the value in Federal agencies working with States to anticipate growth in emissions and include those anticipated emissions in the applicable SIP. The EPA is in the process of proposing regulatory amendments to the General Conformity regulations that provide a framework for Federal facilities to work with States to account for facility-wide emissions in SIPs and to include Federal facility emissions in future SIPs. The EPA anticipates that these rule amendments should be proposed before the end of summer 2006.

Comment: Some commenters stated that the *de minimis* level for $PM_{2.5}$ for conformity applicability should be less than 100 tons per year. A level of 50 tons per year was suggested for direct $PM_{2.5}$ emissions.

Response: Similar comments were received when the $PM_{2.5}$ *de minimis* level was proposed on April 5, 2006. The response to those comments can be found in the preamble to the final rule setting the *de minimis* level for $PM_{2.5}$ at 71 FR 40420.

Comment: Are the precursors for general conformity consistent with this rulemaking or with the transportation conformity rulemaking?

Response: The precursors for general conformity are generally consistent both with this rule and the transportation conformity rule. The only difference between the transportation rule and this rule is that SO_2 is not considered a precursor for transportation conformity determinations that occur prior to a $PM_{2.5}$ SIP unless EPA or the State air agency finds on-road mobile source emissions significant. For more information, see the May 6, 2005 transportation conformity rule on $PM_{2.5}$ precursors at 70 FR 24283. Since general conformity includes analysis of stationary sources the general conformity rule requires SO_2 as a precursor both before and after a $PM_{2.5}$ SIP is submitted.

Comment: When will rulemaking containing the *de minimis* levels for $PM_{2.5}$ and for the precursors be issued? There is some confusion, since the proposed rule says that states should assume 100 tpy for all $PM_{2.5}$ pollutants, as this would make it consistent with the levels for NO_X and VOC for the subpart 1 areas under 8-hour ozone. However, since New Jersey's classification is moderate under the 8-hour ozone standard and we are in an Ozone Transport Region, the *de minimis* level for VOC is 50 tons per year.

Response: On July 17, 2006 EPA issued a final rule (71 FR 40420) to amend the General Conformity Regulations to establish *de minimis* levels for $PM_{2.5}$ for the General Conformity program. The final rule established 100 tons/year of direct $PM_{2.5}$ emissions and its precursors as the *de minimis* level where the General Conformity regulations would apply in $PM_{2.5}$ nonattainment areas. Since EPA is not finalizing any classifications for the $PM_{2.5}$ nonattainment areas, we did not establish differing $PM_{2.5}$ *de minimis* emission levels for based on a classification scheme.

Comment: If a Statement of Conformity has been issued on a project and if the project has not been completed to date, are they required to address $PM_{2.5}$ prior to completion of the project or will they be grandfathered in?

Response: If a Federal action has completed a conformity determination and the action has started (regardless of whether the project is complete or not) then no new determination is needed. If

the conformity determination was completed, but the action did not start in 5 years a new determination is needed under the general conformity rules.

Comment: What guidance should states use to establish budgets for large facilities or military bases?

Response: The EPA has not issued any guidance for States and Federal facilities to establish facility-wide budgets in the applicable SIP. There is nothing in the General Conformity regulations preventing this approach which would allow Federal actions that do not increase total facility emissions over the budget in the SIP from determining the action conforms on the basis of its compliance with the budget limit. The EPA sees this practice as a positive step to encourage States and Federal agencies to work together to account for emissions in a SIP so they conform with the purposes and goals of the SIP. The EPA intends to address the approach and provide guidance in planned revisions to the General Conformity regulations which are expected to be proposed in 2006.

K. Emission Inventory Requirements

a. Background

Emission inventories are critical for the efforts of State, local, tribal and federal agencies to attain and maintain the NAAQS that EPA has established for criteria pollutants including $PM_{2.5}$. Pursuant to its authority under section 110 of Title I of the CAA, EPA has long required States to submit emission inventories containing information regarding the emissions of criteria pollutants and their precursors. The EPA codified these requirements in 40 CFR part 51, subpart Q in 1979 and amended them in 1987.

The 1990 CAAA revised many of the provisions of the CAA related to attainment of the NAAQS and the protection of visibility in mandatory Class I Federal areas (certain national parks and wilderness areas). These revisions established new emission inventory requirements applicable to certain areas that were designated nonattainment for certain pollutants. In the case of particulate matter, the emission inventory provisions are in the general provisions under Section 172(c)(3).

In June 2002, EPA promulgated the Consolidated Emissions Reporting Rule (CERR) (67 FR 39602; June 10, 2002), 40 CFR part 51 subpart A. The CERR consolidated the various emissions reporting requirements that already existed into one place in the CFR, established new reporting requirements for $PM_{2.5}$ and ammonia, and established new requirements for the statewide reporting of area source and mobile source emissions.

The CERR established two types of required emission inventories: annual inventories, and 3-year cycle inventories. The annual inventory requirement is limited to reporting statewide emissions data from the larger point sources. For the 3-year cycle inventory, States need to report data from all of their point sources plus all of the area and mobile sources on a statewide basis. A special case existed for the first 3-year cycle inventory for the year 2002 which was due on June 1, 2004.

The EPA issued guidance suggesting that 2002 be used as the Base Year for 8-hour ozone, $PM_{2.5}$ and regional haze planning efforts (November 18, 2002 EPA memorandum ''2002 Base Year Emission Inventory SIP Planning: 8-hr Ozone, $PM_{2.5}$ and Regional Haze Programs'' *http://www.epa.gov/ttn/chief/eidocs/2002baseinven_102502new.pdf*).

States should estimate mobile source emissions by using the latest emissions models and planning assumptions available at the time the SIP is developed. Information and guidance on the latest emissions models is available at *http://www.epa.gov/otaq/stateresources/transconf/policy.htm#models* and at *http://www.epa.gov/otaq/models.htm.*

By merging the information on point sources, area sources and mobile sources into a comprehensive emission inventory, State, local and tribal agencies may do the following:

- Set a baseline for SIP development.
- Measure their progress in reducing emissions.
- Have a tool to support future trading programs.
- Answer the public's request for information.

The EPA uses the data submitted by the States to develop the National Emission Inventory (NEI). The NEI is used by EPA to show national emission trends, as modeling input for analysis of potential regulations, and other purposes.

Most importantly, States need these inventories to help in the development of control strategies and demonstrations to attain the annual and 24-hour $PM_{2.5}$ NAAQS. In April 1999, EPA published the ''Emissions Inventory Guidance for Implementation of Ozone and Particulate Matter National Ambient Air Quality Standards (NAAQS) and Regional Haze Regulations,'' EPA–454/R–99–006. The EPA updated this guidance in November 2005.[46] The current version of this guidance is available at: *http://www.epa.gov/ttn/chief/eidocs/eiguid/index.html.* The EPA developed this guidance document to complement the CERR and to provide specific guidance to State and local agencies and Tribes on how to develop emissions inventories for 8-hour ozone, $PM_{2.5}$, and regional haze SIPs. While the CERR sets forth requirements for data elements, EPA guidance complements these requirements and indicates how the data should be prepared for SIP submissions.

The SIP inventory must be approved by EPA as a SIP element and is subject to public hearing requirements, whereas the CERR is not. Because of the regulatory significance of the SIP inventory, EPA will need more documentation on how the SIP inventory was developed by the State as opposed to the documentation required for the CERR inventory. In addition, the geographic area encompassed by some aspects of the SIP submission inventory will be different from the statewide area covered by the CERR emissions inventory. The CERR inventory was due June 1, 2004, while the SIP inventory due date is later. Because of this time lapse, the State may choose to revise some of the data from the CERR when it prepares its SIP inventory to account for improvements in emissions estimates. If a State's 2005 emission inventory (or a later one) becomes available in time to use for timely development of a nonattainment area SIP, then that inventory can be used. We also encourage the cooperation of the Tribes and the State and local agencies in preparing their emissions inventories.

b. Final Rule

In the proposed rulemaking, in § 51.1008(a), to meet the emission inventory requirements of section 172(c)(3), EPA proposed to require submission of the CERR inventories as well as ''any additional emission inventory information needed to support an attainment demonstration and RFP plan ensuring expeditious attainment of the annual and 24-hour $PM_{2.5}$ standards.'' Section 51.1008(b) set forth specifications for baseline emissions inventories for attainment demonstrations and RFP requirements. Section 51.1008 of the final rule reflects our proposed rule but is different from the draft regulatory text. The proposal did not specify a deadline for

[46] Emissions Inventory Guidance for Implementation of Ozone and Particulate Matter National Ambient Air Quality Standards (NAAQS) and Regional Haze Regulations,'' (EPA–454/R–05–001, November 2005.

submission of the emission inventory. To ensure clarity, the final rule contains language addressing the deadline for submission of emissions inventories for nonattainment areas under section 172(c)(3) and section 172(b), and reflects the statutory requirement of no later than 3 years after designation of the area. See § 51.1008(a). In addition, § 51.1008(a)(1) of the proposed rule has been changed for purposes of clarification. The proposal referred to the requirement to submit statewide emission inventories under the (CERR), contained in 40 CFR part 51, subpart A. The final regulatory text clarifies this to refer to the requirements for data elements under 40 CFR part 51, subpart A. The EPA did not intend that the emissions inventories developed under the CERR, which are statewide, would be appropriate for and satisfy all aspects of SIP inventories developed for SIP submissions. Section 51.1008(b) has a minor change to clarify that this subsection refers to the inventories required for submission under paragraph (a) of section 51.1008, and also clarifies the reference to 40 CFR Part 51 subpart A, which currently contains the CERR. In addition, section 51.1008(b) as finalized provides that ''The baseline emission inventory for calendar year 2002 or other suitable year shall be used for attainment planning and RFP plans for areas initially designated nonattainment for the $PM_{2.5}$ NAAQS in 2004.'' The EPA added this flexibility to be consistent with EPA's ozone implementation rule, and to enable a State to use a more recent and improved base year inventory if it is completed in time to allow for timely development of the attainment plan. As noted above, we expect that States will consult the guidance document titled *Emission Inventory Guidance for Implementation of Ozone and Particulate Matter National Ambient Air Quality Standards (''NAAQS'') and Regional Haze Regulations,* November 2005,and submit inventories that are appropriate for the geographic area at issue and consistent with regulations and this guidance. We expect the States to include in their SIP submission documentation explaining how the emissions data were calculated.

In the proposed rulemaking, EPA asked ''What emission inventory requirements should apply under the $PM_{2.5}$ NAAQS.'' Several specific questions followed this general question to assess whether or not additional emission inventory requirements or guidance are needed to implement the proposed standard. It was noted in the proposal that the basis for EPA's emission inventory program is specified in the Consolidated Emissions Reporting Rule (CERR) and the related guidance document titled *Emissions Inventory Guidance for Implementation of Ozone and Particulate Matter National Ambient Air Quality Standards (NAAQS) and Regional Haze Regulations.*

Subsequent to the proposed rulemaking, EPA proposed the Air Emissions Reporting Rule (AERR) at 71 FR 69 (Jan. 3, 2006). The AERR would update CERR reporting requirements by consolidating and harmonizing new emissions reporting requirements with pre-existing sets of reporting requirements under the Clean Air Interstate Rule (CAIR) and the NO_X SIP Call. At this time, EPA is reviewing comments submitted on the AERR proposal and expects to finalize this rulemaking during calendar year 2007. The AERR is expected to be a means by which the Agency will implement additional data reporting requirements for $PM_{2.5}$ SIP emission inventories. Since the AERR rulemaking is in progress, EPA believes it is appropriate to defer responding to certain comments on the proposed $PM_{2.5}$ Implementation Rule related to data reporting and emission inventory requirements that were discussed in the AERR proposal. Those comments will be addressed in the final AERR rulemaking. Significant comments that are separable from the AERR rulemaking and relate to data reporting and emission inventory requirements for the $PM_{2.5}$ NAAQS are addressed below and in EPA's Responses to Comments document.

With respect to SIP emission inventory requirements under this rulemaking, EPA recognizes NO_X, SO_2, VOCs, and ammonia as potential precursors of $PM_{2.5}$ because these pollutants can contribute to the formation of $PM_{2.5}$ in the ambient air. To provide a technical foundation for understanding contributions to $PM_{2.5}$ nonattainment problems and for identifying potential future measures to reduce $PM_{2.5}$ concentrations, EPA is requiring under 40 CFR part 51 subpart A and 40 CFR 51.1008 of this rule that States develop and submit inventories for direct $PM_{2.5}$ and all precursors of $PM_{2.5}$. This requirement stands apart from the policies in this rule regarding the required treatment of various precursor emissions in the development of control strategies for attaining the $PM_{2.5}$ standards. With respect to the latter requirements, EPA has not made a finding that all precursors should be evaluated for potential control measures in each specific nonattainment area. The policy approach in the rule instead requires evaluation of control measures for direct $PM_{2.5}$ and sulfur dioxide in all areas, and describes general presumptive policies that NO_X sources need to be evaluated for control measures in all areas unless findings of insignificance are made, but that control measure evaluations are not required for sources of ammonia and VOC unless findings of significance are made. The rule also provides a mechanism by which the State and/or EPA can make an area-specific demonstration to reverse the general presumption for these three precursors. (See section II.A.8 for additional discussion on these issues.)

c. Comments and Responses

1. Should EPA Specify an Inventory Approval Process?

Comment: Several commenters indicated that the current process of approving SIP inventories by EPA regional offices is appropriate and did not believe that additional approval requirements were necessary. Some commenters noted that flexibility is needed to address regional concerns. Several commenters noted that SIP emission inventories may include requirements or information in addition to data required by the Consolidated Emissions Reporting Rule (CERR). One commenter observed that States routinely develop information outside the CERR for purposes of their SIP development and that additional requirements should not be defined by EPA. Another commenter recommended that requirements for nonattainment area emission inventories be incorporated in the CERR or AERR. A few commenters felt that additional guidance was needed on the SIP emission inventory approval process.

Response: The SIP emissions inventory is a plan provision that must be approved by EPA under section 110(k) of the CAA and is subject to public hearing requirements pursuant to section 110(a)(2). The EPA believes that it need not further specify a SIP approval process for emissions inventories beyond that set forth in the statute, regulation (51.1008), other related sections of this rulemaking and EPA's current guidance. The EPA agrees with many of the commenters that the approval process for SIP emission inventories need not be further defined and that approval should be conducted at the regional level to provide flexibility to address regional concerns. The EPA also agrees that use of Quality Assurance Project Plans developed for each state will be helpful in establishing the proper approval process. The EPA

addresses the issue of what data elements are needed for SIP approval in the responses to comments below, including the responses to comments under Issue 2, below.

As noted by two commenters EPA describes procedures for approval of SIP inventories in a document titled *Emissions Inventory Guidance for Implementation of Ozone and Particulate Matter National Ambient Air Quality Standards (NAAQS) and Regional Haze Regulations,* November 2005. Section 2.5, Inventory Approval, references a memorandum titled *Public Hearing Requirements for 1990 Base-Year Emissions Inventories for Ozone and CO Nonattainment Areas, September 29, 1992.* The EPA intends to use the procedures discussed in the guidance and memorandum to the extent that they are applicable to approval of $PM_{2.5}$ emission inventories submitted as part of the SIP. 40 CFR 51.1008 sets forth the requirements for emissions inventories under section 172(c)(3), which will be reviewed in the context of the SIP approval process. See also 40 CFR 51.1007 and 51.1009 regarding attainment demonstrations and RFP plans. Thus, EPA believes that its existing SIP approval process is adequately described in statute, regulation and guidance, and that it provides flexibility to deal with issues that arise in individual nonattainment areas.

2. Are the Data Elements Specified Within the CERR Sufficient To Develop Adequate SIPs? For Example, in the Determination of RACT, Should More Information on Existing Control Devices Be Required?

Comment: Several commenters recommended that any additional reporting requirements should be addressed through the CERR/AERR and associated guidance and that no additional reporting requirements should be specified in the Rule. Another commenter stated that more detail concerning control equipment would be helpful but was concerned about the additional burden on industry compared to the benefit to State and local agencies, and suggested that this would be further addressed in the context of comments on the AERR. One commenter believed that the reporting requirements within the CERR are sufficient to develop a $PM_{2.5}$ SIP for most areas but noted that nonattainment areas may require additional inventory information which will need evaluation on a case-by-case basis. The commenter further stated that any additional inventory requirements should be identified during the SIP development process, in cooperation with the EPA regional office, and should not be part of this rule.

Response: In section 40 CFR 51.1008(a)(1) of the final rule, EPA incorporates the requirements for data elements required under 40 CFR part 51, subpart A, which contains the CERR, for inventories submitted under this section. The EPA notes, however, that the issue of whether to require additional reporting requirements beyond those required in the CERR is currently being addressed in the Air Emissions Reporting Rule (AERR) 71 FR 69 (January 3, 2006). At this time EPA believes that the requirements for data elements under the CERR, in conjunction with the other provisions of 40 CFR 51.1008, as well as 40 CFR 51.1007 and 51.1009, are generally adequate to meet the needs for $PM_{2.5}$ nonattainment emission inventory SIP development. The AERR as proposed includes additional provisions which may be helpful for $PM_{2.5}$ SIP emission inventory development. The EPA will address this aspect of the AERR, including comments received in this rulemaking on the issues raised and the additional elements proposed in the AERR, in the final AERR rulemaking. This final rule indicates that States shall include data elements for $PM_{2.5}$ inventories as required under 40 CFR part 51, subpart A. In addition, 40 CFR 51.1008(a)(2) requires that States submit ''any additional emission inventory information needed to support an attainment demonstration and RFP plan ensuring expeditious attainment of the annual and 24-hour $PM_{2.5}$ standards.'' See also 40 CFR 51.1007 and 51.1009. Thus States should be aware that data elements in addition to those required under the CERR may be needed to support attainment demonstrations and RFP inventories. Additional data elements needed for other SIP emission inventory purposes should be handled on a case-by-case basis. Because of the nature of SIP development, which varies depending on the nature and needs of individual areas, it may not be possible to require a level of detail in regulations that will enable a ''one-stop-shop'' information request as suggested by one of the commenters.

As recommended by one commenter, guidance on reporting requirements is contained in *Emissions Inventory Guidance for Implementation of Ozone and Particulate Matter National Ambient Air Quality Standards (NAAQS) and Regional Haze Regulations* (EPA–454/R–05–001, November 2005). For example, Section 3.2.1 for Pollutant and Pollutant Precursors to be Inventoried presents guidance to states on $PM_{2.5}$ pollutants and their components that should be reported for $PM_{2.5}$ SIP development. See also section 5, Emission Inventory Development, and other related sections of the guidance.

With respect to the comment on additional detail on control requirements, see also EPA's Response to Comment Document.

3. Is the Current Approach for Reporting Specific Pollutants Sufficient, or Should EPA Require More Specific Emission Component Reporting Such as Groups of Compounds or Reporting of Elemental Carbon and Organic Carbon?

Comment: Currently the CERR requires the reporting of SO_2, VOC, NO_X, CO, Pb, PM_{10}, $PM_{2.5}$, and NH_3. VOC and PM are speciated by the emissions processing models based on speciation profiles for specific source categories. Most commenters supported retaining the existing reporting requirements under the CERR. Others encouraged expansion of the requirements to include reporting of specific organic compounds and organic fractions although some thought this should be a requirement while others thought it should be optional. One commenter thought that EPA should work with industry trade groups to develop and improve the speciation profiles of the most important source categories rather than asking the state and local agencies to characterize VOC and PM species. Several commenters thought that EPA should encourage the reporting of PM components (filterable, condensable and total) for development of control strategies and attainment demonstrations. Another commenter noted that including condensable emissions raises ''uncertainty'' issues and urged EPA to devote resources to developing better test methods. One commenter believed that in addition to reporting $PM_{2.5}$ and its components, states should report all precursors to $PM_{2.5}$ (SO_2, NO_X, ammonia and VOC).

Response: The EPA agrees with the commenters who argued that the need for additional speciation should be determined based on specific SIP needs. 40 CFR part 51, subpart A which contains the CERR, does not require reporting of specific compounds or compound groups nor does it require reporting of organic and elemental carbon fractions. As discussed in the response to comment above, EPA believes that the requirements for data elements contained in 40 CFR part 51 subpart A, in conjunction with the provisions of 40 CFR 51.1008, are generally adequate to meet the needs for $PM_{2.5}$ nonattainment emissions

inventory SIP development. Section 51.1008(a)(1) applies the data element requirements contained in 40 CFR part 51 subpart A. Section 51.1008(a)(2) requires States to submit ''any additional emission inventory information needed to support an attainment demonstration and RFP plan ensuring expeditious attainment of the annual and 24-hour $PM_{2.5}$ standards.'' Thus data elements in addition to those required under the CERR may be needed to support attainment demonstrations and RFP inventories under 40 CFR 51.1008(a)(2). Additional data elements needed for other SIP emission inventory purposes should be handled on a case-by-case basis. Where States need to develop speciated emissions for $PM_{2.5}$ SIP emission inventories, EPA provides guidance in the document titled *Emissions Inventory Guidance for Implementation of Ozone and Particulate Matter National Ambient Air Quality Standards (NAAQS) and Regional Haze Ozone Regulations,* November 2005. Section 3.2.1, Pollutants and Pollutant Precursors to be Inventoried identifies pollutants and their components to be reported for $PM_{2.5}$ SIPs. Section 3.3.5, Speciation Procedures, discusses the preferred approach for speciating $PM_{2.5}$ emission inventories for use in ambient air quality simulations. The approach discussed in the guidance is application of emission models which use speciation profiles to estimate the mass of specific compounds and compound groups for VOC and elemental and organic carbon fractions for PM. The EPA encourages further research and development of technical tools to better characterize emissions inventories for specific VOC compounds and to determine the extent of specific VOC compounds and organic PM mass. The EPA also encourages States to continue efforts to refine their ammonia inventories. See sections II.A.3 and II.A.4 of the Preamble.

As discussed in the guidance document, EPA encourages reporting of organic and elemental fractions of $PM_{2.5}$ by state agencies (see Section 3.2.1, Pollutants and Pollutant Precursors to be Inventoried). While elemental or black carbon (EC/BC) and organic carbon (OC) will be identified in default speciation profiles, more locally-specific data should be collected where available as an input to model preprocessing. Where such data are available, they should be provided to EPA to help in improving EPA's speciation profiles. Certain organic gases have been identified as precursors to secondary organic aerosols (SOA). Toluene, xylene and ethyl benzene are known to be important SOA precursors. Additional organic gases may be identified by ongoing research. While these gases will be identified in default speciation profiles, more locally-specific data should be collected, where available, as an input to model preprocessing. State, local and Tribal agencies can contact EPA's EIAG for more information.

EPA agrees with the comment that it should take the lead in updating VOC and PM profiles for most important source categories. The Agency is close to completing a multi-year effort to update the SPECIATE database. SPECIATE is EPA's repository of Total Organic Compound (TOC) and PM speciated profiles for a wide variety of sources. The profiles in this system are provided for air quality dispersion modeling and as a library for source-receptor and source apportionment type models. This recent initiative to update SPECIATE was needed because speciated emissions profiles continue to be developed and the data in the existing EPA database (SPECIATE 3.2) was becoming outdated.

This work was coordinated with interested parties including industry through an Agency sponsored workgroup. It has depended largely on the collection and review of existing profile data to accomplish, as the commenter suggests, delivering the best results for the least amount of resources spent. Previously, these data were not widely available to emission inventory developers and lacked the quality assurance review and evaluation needed to develop profiles used by emissions models to generate speciated emissions. As suggested by the commenter, the workgroup was used to help prioritize source categories for investigation to ensure that updates to existing profiles and development of new profiles focused on areas of greatest need.

SPECIATE v4.0 contains more than 2500 source profiles and is currently undergoing peer review. The EPA expects the final work product to be available for use by emission inventory preparers during early calendar year 2007 and it will be distributed through EPA's CHIEF Web site.

The EPA agrees with a commenter who noted that in order to meet the requirements under section 172(c) of the CAA for ''a comprehensive, accurate, current inventory * * *,'' condensable emissions of $PM_{2.5}$ and $PM_{2.5}$ precursors are important to support development of local control strategies and attainment demonstrations. The EPA believes that the final rule provides for the submission of $PM_{2.5}$ nonattainment area inventories meeting the requirements of section 172(c)(3).

Section 51.1008(a)(1) requires that States submit emission inventories for $PM_{2.5}$ that satisfy the data elements reporting requirements under 40 CFR part 51 subpart A, which contains the CERR. The CERR requires reporting of ''Primary $PM_{2.5}$'' which is defined as the sum of the filterable and condensable portions of $PM_{2.5}$. Therefore, SIP base year inventories will include the condensable fraction of PM which was of concern to several commenters. The CERR also requires reporting of SOx, NO_X, ammonia and VOC which are potential precursors to $PM_{2.5}$. EPA notes that the AERR as proposed would require reporting of the same precursors and would also require reporting of Primary $PM_{2.5}$. However, the proposed AERR requires the reporting of the filterable and condensable fractions of $PM_{2.5}$ (optional under the CERR) in addition to the primary $PM_{2.5}$ total mass. The EPA will address this requirement in its final rulemaking on the AERR.

As noted above, in addition to the data element requirements under section 51.1008(a)(1), under section 51.1008(a)(2) States must submit ''any additional emission inventory information needed to support'' an attainment demonstration and RFP plan. Thus States should be aware that data elements in addition to those required under the CERR may be needed to support attainment demonstrations and RFP inventories under 40 CFR Part 51.1008(a)(2). Additional data elements needed for other SIP emission inventory purposes should be handled on a case-by-case basis.

The EPA is aware of the issues raised by one commenter regarding measurement uncertainty for condensable PM. This issue is addressed in detail under Section II.L of the preamble (''Condensable particulate matter test methods and related data issues,''). We believe that for purposes of emissions inventories and attainment demonstrations, States should continue to describe the impacts of baseline emissions and develop future air quality strategies using information available on primary $PM_{2.5}$ emissions, including condensable $PM_{2.5}$. However, with respect to developing enforceable emissions limits for condensable $PM_{2.5}$ emissions, the final rule reflects EPA's adoption of a transition period during which we will allow time for development of emissions limits for condensable $PM_{2.5}$. See 40 CFR 51.1002(c).

For additional comments and responses related to speciation issues,

see the Response to Comments Document.

4. Should EPA Require That States Develop Their Own Estimates for Area and Mobile Source Emissions?

Comment: The CERR allows states to adopt EPA developed emission estimates from area and mobile sources in lieu of making those estimates themselves if they accept these estimates for their emission inventory. One commenter thought that EPA should require States to develop their own estimates for area and mobile sources based on the specified 2002 base year. Three commenters thought that the existing process (under the CERR) was adequate. One of the commenters expressed concerns about the reporting burden for States if they were required to compile their own mobile and area source inventories. Another commenter did not believe that States should be required to submit data on area and mobile sources but noted that many States would continue to run the MOBILE model for onroad mobile sources and calculate area source data for SIP emission inventories. Two of the commenters thought that the existing process provided flexibility needed by States to focus on source categories of most concern and address problematic areas with special inventory needs. One commenter recommended that EPA continue developing models for area and mobile sources.

Response: The EPA strongly encourages states to submit their own estimates for area (nonpoint) and mobile sources unless they can establish that it is impracticable to do so, given time and resources. We will continue, in appropriate circumstances, to allow a State to use EPA-developed emission estimates for mobile and nonpoint sources in lieu of making those estimates itself if the State accepts the estimates for its emission inventory. While this has been the case with respect to reporting under the CERR for the 3-year cycle inventories, for development of emission inventories to support $PM_{2.5}$ SIPs, the ability to rely on EPA-developed emission estimates for development of emission inventories to support $PM_{2.5}$ SIPS is more complex and problematic. For mobile sources, the practical use of these EPA-developed mobile source inventories in a SIP may be very limited. While EPA has developed inventories for 2002, states will still have to develop attainment year inventories, including projections of future activity and the effects of control measures. For mobile sources, future year inventories are not developed by simply growing a base year inventory, but instead are developed by running an emissions model with appropriate inputs for the future year. In order to develop an attainment demonstration that accurately accounts for the change in emissions from the base year to the attainment year, inventories for both of those years will need to be developed using consistent methods and modeling assumptions. For mobile sources especially, it may be very difficult for states to replicate the methods used by EPA for the base year when creating the attainment year inventory.

In addition, states cannot use the EPA developed inventories for the base year if newer models or planning assumptions are available at the time they begin working on the SIP. For example, if new or better information about the composition of the local fleet of highway vehicles in the base year becomes available to the state after the EPA developed inventories were created, that information should be used by the state to create a new base year inventory.

Given the need for emissions modeling for mobile sources in the projection year, the need for consistency in tools and methods between the base year and attainment year, and the need to use latest available models and planning assumptions, EPA believes that most if not all states will choose to develop their own base year inventories for mobile sources.

With respect to nonpoint (area) source emissions, States must make every effort, consistent with available timing and resources to ensure that their area source emission inventories are as accurate as possible. While EPA prepares a national area source emission inventory that covers all counties, it is designed for national analyses. EPA does not have access to the more detailed information available to States that is used to develop an area source inventory. Therefore, states should develop as much of their area source inventory as possible using local and State information, and in particular should develop the inventory for the most significant area source categories which are critical to ensuring overall accuracy. Where time and resources preclude a State from developing the estimates for less-critical area source categories, the State may rely on EPA-developed area source emissions information for those categories.

The EPA points out that although guidance has recommended that 2002 be used as the base year for emissions inventories for states initially designated nonattainment in 2004–5, states remain free to use an alternate base year, as appropriate. Section 51.1008(b) provides in relevant part that ''The baseline emission inventory for calendar year 2002 or other suitable year shall be used for attainment planning and RFP plans for areas initially designated nonattainment for the $PM_{2.5}$ NAAQS in 2004.''

EPA agrees with the comment that it should continue to develop models and other emission estimation tools. As an example, EPA's Office of Transportation and Air Quality (OTAQ) is developing a modeling system termed the Motor Vehicle Emission Simulator (MOVES). This new system will estimate emissions for on-road and nonroad sources, cover a broad range of pollutants, and allow multiple scale analysis, from fine-scale analysis to national inventory estimation. When fully implemented MOVES will serve as the replacement for MOBILE6.2 and NONROAD. In addition, as the NEI is reengineered, OAQPS will examine the need for updating emissions estimation guidance materials and developing tools which will assist State agencies in estimating emissions from area source categories. See also EPA's ''Emissions Inventory Guidance for Implementation of Ozone and Particulate Matter National Ambient Air Quality Standards (NAAQS) and Regional Haze Regulations,'' November 2005.

5. Other Inventory Issues

The EPA's responses to additional comments concerning emission inventory issues can be found in EPA's Response to Comments Document.

L. Condensable Particulate Matter Test Methods and Related Data Issues

a. Background

As noted in the preamble to the November 1, 2005 proposed rule, certain commercial or industrial activities involving high temperature processes (fuel combustion, metal processing, cooking operations, etc.) emit gaseous pollutants into the ambient air which rapidly condense into particle form. The constituents of these condensed particles include, but are not limited to, organic material, sulfuric acid, and metals. Because condensable emissions exist almost entirely in the 2.5 micrometer range and smaller, these emissions are inherently more significant for $PM_{2.5}$ than for prior particulate matter standards addressing larger particles. Therefore, we believe that it is important that the air quality management of particulate matter promote a comprehensive approach to condensable particulate matter.

We proposed to require a comprehensive inclusion of condensable PM for all aspects of SIP development for $PM_{2.5}$. Under the proposal, EPA would require condensable PM to be considered in the emissions inventories and analyses used in attainment demonstrations. Also under the proposal, any stationary source emissions limits developed to implement RACT or RACM would reflect control and measurement of condensable PM.

We received numerous comments on whether these requirements were unreasonable in light of the current state of knowledge of and uncertainties around the measurement of direct $PM_{2.5}$. Most commenters supported the overall view that condensable PM should be addressed in order to provide a complete air quality management program for $PM_{2.5}$. On the other hand, many commenters raised concerns about the availability and implementation of test methods and related issues about the uncertainties in existing data for condensable $PM_{2.5}$. As a result of the concerns, these commenters believed EPA would be premature in requiring a comprehensive evaluation of condensable $PM_{2.5}$, especially as it related to developing any new emissions limits for stationary sources. In recognition of these concerns, the final rule reflects EPA's adoption of a transition period during which we will assess possible revisions to available test methods and we will allow time for States to update emissions inventories as needed to address direct $PM_{2.5}$ emissions. In this section of the preamble, we outline the elements of the final rule addressing inventories reflecting control of direct $PM_{2.5}$. We also discuss the specific comments raised regarding methods for measuring direct $PM_{2.5}$, both filterable and condensable PM, in implementing the rule. The particular comment areas include defining test methods, quantifying direct $PM_{2.5}$ for inventories, and a transition period for developing effective regulations. Below are also our responses to those comments.

b. Final Rule

For the final rule, EPA addresses two broad issues related to inclusion of condensable PM. The first issue is whether emissions inventories and attainment demonstrations should include the condensable portion of direct $PM_{2.5}$ emissions. The second issue is whether direct $PM_{2.5}$ emissions limitations established by States for purposes of RACT and RACM must include limits on condensable PM emissions or limits on total direct $PM_{2.5}$ that includes the condensable PM fraction.

For purposes of developing emissions inventories and attainment demonstrations, the final rule reflects a requirement to account for significant contributors of direct $PM_{2.5}$ emissions, both filterable and condensable $PM_{2.5}$. We recognize that some States have established inventories consistent with requirements of the consolidated emissions reporting rule (CERR) to report direct $PM_{2.5}$ emissions, including condensable PM, in each inventory revision. While uncertainties remain with significant issues to address related to our current knowledge base on condensable PM emissions, we believe that for purposes of emissions inventories and attainment demonstrations, States should continue to describe the impacts of baseline emissions develop future air quality strategies using information available on direct $PM_{2.5}$ emissions including condensable PM.

With respect to developing enforceable emissions limits for condensable PM emissions, we note that some States have established emissions limits or otherwise require PM emissions testing that includes measurement of condensable PM. We recognize that in some States there remain questions about the viability of available test methods, the availability of representative direct $PM_{2.5}$ emissions data, the uncertainty of the methods used to establish inventories, and the short time frame within which States must develop SIPs. In response we have decided to provide a transition period for developing emissions limits and regulations for condensable $PM_{2.5}$. During this transition period, we will provide technical support to States as requested in establishing effective $PM_{2.5}$ emissions limits and corresponding emissions testing requirements.

As described further below, we will devote resources early during this transition period to assessing and improving the available test methods for condensable PM. During this transition period, we will also solicit the involvement of stakeholders with an interest in conducting emissions testing to collect updated direct $PM_{2.5}$ emissions data. The purpose of these stakeholder projects will be to collect new direct filterable and condensable PM emissions data using methodologies that provide data more representative of source direct $PM_{2.5}$ emissions. The EPA, States, and others will use these data to improve emissions factors and to help define or revise source emissions limits in permits and State implementation plans.

The time required for our stakeholders and EPA to complete the test method assessment will limit the degree to which State and local agencies can address effectively the necessary direct $PM_{2.5}$ regulations in inventories and in the 2008 SIP submittals. In recognition of this, we will not require that the emissions limits included in the 2008 submittals account for the condensable fraction of direct $PM_{2.5}$ or to establish limits for total direct $PM_{2.5}$, including condensable PM.

We will expect States to continue developing more complete inventories with regard to direct $PM_{2.5}$ emissions, particularly for condensable PM, during this transition period. We expect no such allowance period for method assessment or data collection to be necessary for implementing regulations addressing precursor $PM_{2.5}$ emissions.

The period of transition for establishing emissions limits for condensable direct $PM_{2.5}$ will end January 1, 2011. We expect States to address the control of direct $PM_{2.5}$ emissions, including condensable PM, with any new actions taken after January 1, 2011. For example, States must address condensable PM emissions in any direct $PM_{2.5}$ emissions limits resulting from midcourse reviews. Additionally, EPA expects that any direct $PM_{2.5}$ regulations or limits developed under any new NAAQS for particulate matter would also address condensable PM emissions.

Notwithstanding the issues and uncertainties related to condensable PM, EPA encourages States to identify measures for reducing condensable PM emissions, particularly where those emissions are deemed significant contributors to the control strategy needed for expeditious attainment. We wish to clarify that in order to take credit in the SIP for reduction of any such condensable PM emissions, there must be enforceable limitations that ensure that reduction in condensable PM emissions. These enforceable limits could take the form of a limitation on the condensable PM emissions or total direct $PM_{2.5}$ emissions (or a commitment to develop such limitations after the end of the transition period described above). Alternatively, these enforceable limitations could provide for enforceable conditions that ensure that the effect on condensable PM emissions is assured (for example, enforceable limitations on operating temperature, or limits on FGD scrubber operations which have the effect of reducing condensable PM emissions).

c. Comments and Responses

We received many comments on quantification of direct $PM_{2.5}$ emissions particularly about the need to conduct further validations for the available test methods, the availability of direct filterable or condensable $PM_{2.5}$ data or lack thereof for representative baselines, and the procedures for applying baseline data for developing effective regulations.

1. Method 202

Comment: A majority of commenters characterized the performance of Method 202 as lacking in reliability. Some commenters characterized the formation of artifacts in Method 202 as significant and the primary reason for their recommendation to defer the inclusion of condensable particulate matter in the baseline assessments and regulatory development for the initial SIPs. The commenters stated that the principal artifact formed when using Method 202 was the result of SO_2 dissolving in the impinger water and converting to sulfuric acid.

Response: We agree that SO_2 in particular, and perhaps other gaseous compounds, can react with the collecting liquids used in the method to form materials (artifacts) that would not otherwise be solid or liquid or would not condense upon exiting the stack. We believe that when Method 202 is applied appropriately (i.e., with the N_2 purge as prescribed), the SO_2 artifact formation is reduced by as much as or more than 90 percent; however, we agree that further verification and refinement would be appropriate to verify the potential for artifact formation.

In response, we are undertaking laboratory studies in collaboration with several stakeholders to characterize the artifact formation and other uncertainties associated with conducting Method 202, and to identify procedures to be used in applying methods to minimize uncertainties. We are involving stakeholders representing industry and State and local agencies in the project design and results review. Stakeholders who have expressed interest in participating in these studies include the Electric Power Research Institute, companies associated with the National Environmental Development Association's Clean Air Project (NEDA/CAP), the Portland Cement Association, the Lime Manufacturing Association, the American Foundry Association, the National Aluminum Association, and several governmental organizations represented by National Association of Clean Air Agencies. Other parties may participate in the study as well.

By the end of 2007, we intend to have conducted a comprehensive laboratory study that examines the relationship between several critical condensable PM sampling and analysis parameters (e.g., SO_2 concentration, moisture concentration, sample duration, and water acidity) and the artifact formation associated with the measurements. One intended result of the project will be identifying possible modifications to Method 202 to minimize and quantify the uncertainties. We will publish the results of the laboratory study along with an assessment of other input and data from stakeholders on the EPA website and, to the extent possible, in a widely circulated peer review journal. Also, to the extent necessary, we intend to propose revisions to the method to incorporate improvements and to clarify application.

2. Conditional Test Methods 039 and 040

Comment: Several commenters cited as a deficiency that neither conditional test method 040 (CTM–040) for measuring filterable $PM_{2.5}$ nor the dilution sampling method (CTM–039) has been thoroughly validated through EPA Method 301. There were also comments that neither of the CTMs was published in the **Federal Register**.

Response: We agree with the comments that neither method has been subjected to adequate public notice and comment rulemaking. Taking that step will facilitate application of the appropriate methods for implementing the SIPs. On the other hand, there are a number of levels of validation already achieved for one or more of these methods that will determine what, if any, additional validation work will be necessary. For example, while we could seek resources to evaluate dilution sampling technology, including CTM–039, and to request public involvement in the project planning, conduct, and review with the possibility of a **Federal Register** proposal, our preference would be to incorporate by reference an approved voluntary consensus test method (e.g., ASTM standard).

We believe that a dilution sampling method for measuring direct $PM_{2.5}$ eliminates essentially all artifact formation and provides the most accurate emissions quantification. To the extent that we need to and can secure resources and stakeholder interest, we plan to perform additional validation testing of CTM–039 or other dilution sampling technologies to characterize the precision of this approach. In conjunction with our validation efforts, we intend to continue participation in the ASTM D22 committee to develop and publish a dilution sampling method and encourage other volunteers on that committee to approve the consensus based dilution sampling method. We believe that this work is nearly complete. As outlined above, we are already undertaking laboratory studies to assess the method and to identify possible modifications to reduce formation of these artifacts. Preliminary laboratory evaluations conducted by EPA and by Environment Canada[47] indicate that additional artifact reductions of 60 to 90 percent may be achieved with other minor modifications to Method 202. These preliminary findings indicate that Method 202 is essentially a viable method that these proposed laboratory studies will serve to enhance. Within 18 months we intend to propose, if necessary, modifications to Method 202 or similar methodologies suitable for measuring condensable $PM_{2.5}$.

As for CTM–040, we believe that further validation of this method is unwarranted since the technology and procedures are based upon the same as evaluated for promulgated Method 201A. Method 201A has undergone public review and comment (55 FR 14246, April 17, 1990). Also, as noted earlier, we have already begun laboratory and data evaluation work the possible result of which would be a revised Method 202 to be proposed in the **Federal Register** to include improvements indicated by the evaluation. At that same time, we may propose CTM–040 to be used in combination with Method 202 for measuring direct $PM_{2.5}$ with additional guidance on appropriate approaches to testing for direct $PM_{2.5}$ emissions from various types of control measures (e.g., electrostatic precipitator and flue gas desulphurization combinations).

3. Role of Condensable PM Emissions in Defining RACT

Comment: Commenters indicated that States must reassess and revise emissions limits if the States adopt methods for measuring direct $PM_{2.5}$ including condensable PM where not required previously. Commenters noted that most existing PM emissions limits are not reflective of data collected with

[47] ''Optimized Method 202 Sampling Train to Minimize the Biases Associated with Method 202 Measurement of Condensable Particulate Matter Emissions,'' John Richards, Tom Holder, and David Goshaw, Air Control Techniques, P.C.; Air & Waste Management Association, Hazardous Waste Combustion Specialty Conference AWM, November 2–3, 2005, St. Louis, MO.

methods that measure condensable or filterable $PM_{2.5}$ and, therefore, not enforceable using a new or different test method.

Response: We agree that coordinating the test method with the pollutant defined by the emissions limit is critical to an effective regulation. In the case of direct $PM_{2.5}$ regulations, the methods for measuring filterable and condensable PM provide data that are significantly different than do methods often used in implementing many current regulations (i.e., filterable plus condensable $PM_{2.5}$ versus filterable PM only). The existing PM emissions regulations implementing many current SIPs have focused almost exclusively on filterable PM at stack conditions or other elevated temperatures (e.g., 250 °F) with little or no measurement of condensable PM, let alone filterable $PM_{2.5}$. These deficiencies exist in spite of the Agency's policies and guidance presented in documents such as the 1987 PM_{10} SIP Development Guideline [48] and the General Preamble for the Implementation of Title 1 of the Clean Air Act Amendments of 1990 [49] issued in 1992. These documents set forth Agency policy stating that direct PM_{10} and direct $PM_{2.5}$ emissions include both filterable and condensable particulate matter. The policies are reinforced by a 2005 directive from the CAA Advisory Committee.[50]

More to the point, the use of test methods that quantify only filterable PM would limit the capability of any assessment of control measures available for developing cost effective strategies to achieve attainment of the $PM_{2.5}$ NAAQS. Examples include an attainment demonstration that includes control methodologies for PM precursors which are likely to result in a significant decrease in the emissions of direct $PM_{2.5}$ (for example, alkaline scrubbers to reduce SO_2 emissions) and incorporate these direct $PM_{2.5}$ emissions reductions in their attainment demonstration or allow for the use of these reductions as credits for other programs.

Some States may decide to measure and control condensable PM emissions prior to the end of the transition period. To the extent that a State has the supporting technical information and test methods, the State may also assess the capabilities of current control technologies, possible modifications to such technologies, or new technologies as appropriate relative to control of condensable $PM_{2.5}$ emissions in developing effective control strategies and regulations. As an example, a specific approach for controlling condensable PM could be a change in control device operating temperature to achieve necessary emissions reductions. We also note that it is important that implementation of any new or revised rules and test methods should be prospective and clearly differentiated from existing regulations to avoid confusion over status of compliance relative to existing PM emissions limits.

4. Sufficiency of Current Baselines Relative to Direct $PM_{2.5}$ for Regulatory Development

Comment: Many commenters indicated that the currently available baselines for direct $PM_{2.5}$ emissions are not sufficient for States to develop effective emissions control regulations. One commenter claimed that States will need additional information regarding how to arrive at enforceable $PM_{2.5}$ emissions limitations through application of correlations to existing PM_{10} emissions limitations.

Response: We agree that State inventories accounting for direct $PM_{2.5}$ emissions are important to the NAAQS implementation decision-making process. For example, the current national emissions inventories have characterized the contribution of the condensable PM emissions to range from 40 to 80 percent of the direct $PM_{2.5}$ emissions particularly from combustion source categories. We also agree in many cases, the emissions baselines are not sufficiently representative of significant direct $PM_{2.5}$ contributors to allow States to develop effective and enforceable emissions limitations for sources that may require control of direct filterable or condensable $PM_{2.5}$ emissions in order for States to come into attainment with the $PM_{2.5}$ NAAQS.

We note that States are already required under the consolidated emissions reporting rule (CERR) to report direct $PM_{2.5}$ emissions, including condensable PM, in each inventory revision. That means that inventories and associated baselines must address sources and contributions of direct $PM_{2.5}$ emissions, both filterable and condensable PM, from individual sources and groups of sources as well as for future year projected emissions. These data are important for the purposes of calculating emissions reductions and demonstrating that such reductions are attributable to the control measures being implemented.

In taking the process to the next step, we contend that many current baselines established using the available direct filterable and condensable $PM_{2.5}$ national industry average emissions factors (e.g., those found in AP–42 and WebFIRE, *http://www.epa.gov/ttn/chief/efpac/index.html*) often are of quality insufficient to establish effective source-specific emissions limits. First, national industry average emissions factors are subject to significant uncertainties as they usually represent data from a very limited number of example facilities in a category and for a very limited number of operating conditions. Second, the available emissions factors databases may not include direct $PM_{2.5}$ emissions data for specific source types that appear in some State and local inventories.

In short, we believe that States should rely on directly measured emissions data in developing source category or pollutant-specific emissions limits for regulations. This approach is preferable to the use of these national industry average emissions factors such as those found in AP–42. If there are no directly measured emissions data available from the subject sources, national average emissions factors should be used only with appropriate and significant adjustments for uncertainty. Based on our initial study [51] of the uncertainties associated with national average emissions factors when applied to site-specific or rule-development activities, we would expect multipliers of 0.1 to 3.3 for an A-rated national average filterable and condensable direct $PM_{2.5}$ emissions factors. The level of a particular multiplier would depend on how representative of the source category the applicable emissions factor is, the quantity of data supporting that emissions factor, and the specific application. Determining what adjustment may apply for a particular application requires detailed knowledge of the emissions control variability, the expected range of operational and process variability, and the statistical uncertainty in the measured emissions data. While more general adjustments to emissions factors are possible for these purposes, we believe that the better approach is to improve and update the emissions factors used in the database for a particular area with measured

[51] Option Paper 4—Providing Guidance Regarding The Use Of Emissions Factors For Purposes Other Than Emissions Inventories, September 2005, *http://www.epa.gov/ttn/chief/efpac/projects.html.*

direct $PM_{2.5}$ emissions data. For these reasons and to allow time for data collection and analysis, we have determined the need for a period of transition for States in developing direct $PM_{2.5}$ emissions reduction strategies.

5. Transition Period

Comment: Some commenters suggested that EPA should allow States to base their initial 2008 SIPs on NO_X, SO_2, and filterable PM or PM_{10} (as a surrogate for filterable $PM_{2.5}$) rather than require State and local agencies to develop direct $PM_{2.5}$ emissions regulations immediately. Commenters suggested that EPA provide a transition period for sources to adopt SIPs that address direct $PM_{2.5}$ and to apply the appropriate test methods. The commenters proposed that during this transition period, a source should be able to continue to use Method 5, Method 17, or whatever method was used to set the underlying limit contained in the source's title V operating permit. Commenters believe that such a transition plan must provide additional time to collect data related to condensable PM emissions. Commenters believe that this additional time is necessary because it is unrealistic to develop SIP revisions addressing condensable emissions by April 2008. Other commenters suggested that source emissions inventories used for regulatory decision-making and identifying regulatory control measures must be based on accurate measurements.

Response: As outlined above, we agree that a transition period should be allowed to allow time to resolve and adopt appropriate testing procedures for condensable PM emissions, to collect total (filterable and condensable) $PM_{2.5}$ emissions data that are more representative of the sources in their areas, and develop effective regulations for control of direct $PM_{2.5}$, including condensable PM.

6. Data Collection for Regulatory Development

Comment: Several commenters recommended that EPA should be responsible for developing data of emissions from common sources of direct $PM_{2.5}$.

Response: We disagree with the commenters' recommendation that EPA should be primarily or solely responsible for developing baseline data on common sources of direct $PM_{2.5}$ emissions. Commenters are suggesting that we should collect data representative of direct $PM_{2.5}$ emissions from source categories potentially subject to regulation of direct $PM_{2.5}$ emissions. Furthermore, they suggest that we expand or improve the current compilation of national industry average emissions factors such as found in AP–42 and WebFIRE (*http://www.epa.gov/ttn/chief/efpac/index.html*). Given the limited extent to which national industry average emissions factors are suitable for developing State or local regulations that set limits on direct $PM_{2.5}$ emissions, we believe that it is inherent that States instead have primary responsibility for reviewing and applying measured emissions data collected from their sources in enhancing their current baselines. In some cases, this will mean that States and other stakeholders will need to conduct more focused direct $PM_{2.5}$ emissions data collection and improve relevant emissions factors.

This approach is appropriate for several reasons. First, we believe that stakeholders other than EPA are better equipped to identify specific data needs and that they have the means to collect the data. Second, we believe we are better positioned to provide guidance on test planning, data collection, and emissions factors calculations with a less direct role in data collection and evaluation. Third, we believe that States in need of additional information can also benefit from experience of other States with similar source types and who are developing regulations to implement the NAAQS including the control of condensable PM. See also the discussion in section II.L.2.c.1 above on the currently active collaborative study to assess direct $PM_{2.5}$ emissions measurement technologies and to collect updated direct $PM_{2.5}$ emissions data.

7. Developing Effective Regulations for Direct $PM_{2.5}$, Including Condensable PM, Emissions

Most current PM regulations focus on the control and measurement of filterable PM emissions and do not account for condensable PM emissions. At issue are assessing and accounting for the differences in methodology and applicable limits when changing to a program designed to achieve reductions in $PM_{2.5}$ emissions, including condensable PM.

Comment: A number of respondents commented that EPA needs to promulgate a $PM_{2.5}$ test method and adopt regulatory language that determines the $PM_{2.5}$ limits based on that promulgated $PM_{2.5}$ test method as soon as possible. Other commenters suggested that EPA and States have no choice but to revise the underlying standard by adopting new monitoring requirements through a notice and comment rulemaking. Further, these commenters indicate that it is essential that EPA require that no change in a test method or in methods of monitoring for determining compliance until such time as EPA or the permitting agency have undertaken a notice and comment process to determine how the emissions limitations must be revised. A number of commenters cited specific components necessary for effective regulations.

Response: We agree that notice and comment rulemaking is appropriate for establishing effective regulations. As noted above, we are already undertaking a study of the available test methods to determine the need for regulatory revisions. We also agree that new regulations limiting direct $PM_{2.5}$ emissions must include effective emissions limitations to the extent that a State must reduce sources of direct $PM_{2.5}$. How a State determines to take such regulatory action depends on the State's implementation plan. Regarding the specific components necessary for effective regulations, see section O below on enforcement and compliance issues.

M. Improving Source Monitoring

a. Background

In the November 1, 2005 proposal, we discussed a number of actions the EPA would undertake to improve the effectiveness of existing and new regulations with improved source monitoring provisions. Specifically, we repeated a plan outlined on January 22, 2004 (69 FR 3202; a **Federal Register** notice describing requirements for monitoring in operating permits), that includes a four-part strategy for improving monitoring of emissions at the source where necessary through rulemaking. One element of that plan is for EPA to develop guidance on how States can reduce $PM_{2.5}$ emissions by improving source monitoring related to $PM_{2.5}$ emissions limits. We noted that we expect to describe in such guidance methods of improving monitoring frequency or adopting more appropriate monitoring for States to consider in developing their $PM_{2.5}$ SIPs and to illustrate the amount of credit that States could receive in $PM_{2.5}$ SIPs for adopting such improved monitoring. We suggested that States with areas where additional reductions are needed to help the area achieve compliance with the NAAQS could implement improved monitoring measures to obtain additional emissions reductions. We put forward that State agencies could receive SIP credits as a result of enforceable improved monitoring or

voluntary emissions monitoring programs meeting EPA voluntary program policies.

Specific examples of improved monitoring we outlined included: (1) Conducting the currently required monitoring more frequently (i.e., increased monitoring frequency), (2) changing the monitoring technique to a parameter more closely related to control of direct or precursor $PM_{2.5}$ emissions (i.e., a correlated parametric monitoring technique), (3) changing the technique to more measurement of direct $PM_{2.5}$ emissions and $PM_{2.5}$ precursors, or (4) a combination of these improvements. These types of monitoring improvements could be conducted for both controlled and uncontrolled emissions units. The improved monitoring control measure would require facilities to pay more attention to the operation of add-on air pollution control devices, work practices, and other control measure activities. The additional attention will reduce periods during which control devices and other control measures do not operate as intended or required. The result would be increased emissions reductions from implementing existing and new rules.

We discussed a range of currently applied and new monitoring technologies. We addressed concerns we have about the limitations of the widespread use of visual emissions (VE) monitoring techniques, such as visible emissions checks, to show compliance with PM emissions limits. We noted particular concerns about VE approaches, even with frequent application, having the ability to verify compliance when the margin of compliance is small or the ability to detect relatively significant changes in emissions control performance. The other concern we noted about the use of VE tools is the limited frequency at which they are conducted. We cited studies on the availability of continuous instrumental methods for monitoring opacity and operational parameters closely related to PM control levels including the development of repeatable correlations between parameter levels and PM emissions. We noted that PM continuous emissions monitoring systems (PM CEMS) technology provides the opportunity to quantify PM emissions levels (concentration or emissions rates). These additional data provide the source owner/operator with a level of information that can be useful for understanding and operating the process and the control measures in ways to minimize emissions, improve operating efficiencies, and reduce enforcement liabilities. Furthermore, we noted that this technology will provide the State with quantitative information on PM emissions which will help improve the inventories and to implement effective control strategies to meet the NAAQS.

We also discussed at some length what we believe constitutes improved monitoring and the potential for monitoring-related emissions reductions. We discussed a study of how these emissions reductions would be achieved by increasing the monitoring frequency or improving the monitoring of an add-on air pollution control device or other process activity above the level currently required in existing rules. The increased frequency or improved technique would allow owners or operators to achieve greater emissions reductions by identifying and responding more quickly to periods of ineffective control measure operation. States could use an improved monitoring control measure in regulations or through other means to reduce emissions levels and receive credits towards attainment. Specifically, we cited materials that indicate that source owners and operators who increase monitoring frequency could achieve emissions reductions up to 13 percent and those who improve the monitoring technique could achieve emissions reductions up to 15 percent. States with nonattainment areas in need of additional reductions to achieve compliance with the NAAQS could implement an improved monitoring measure and develop additional emissions reductions credits. We outlined several specific examples.

In order to inform our improved monitoring guidance development efforts, we used the 2005 proposal to solicit specific comments on (1) how potentially inadequate source monitoring in certain SIPs could be improved; (2) how improved $PM_{2.5}$ monitoring relates to title V monitoring; (3) whether instrumental techniques are more appropriate than visual emissions (VE) techniques for monitoring compliance with PM emissions limits; and (4) a basis for determining whether improved monitoring would be effective and under what conditions should be required. We also requested comment on the feasibility of monitoring of co-pollutant control measures and requested examples of improved monitoring for any applications.

b. Final Rule

We maintain that improved monitoring is critical to implementing the $PM_{2.5}$ direct and precursor emissions reductions programs. We also believe that improving monitoring both in terms of increasing data collection and analysis frequency and in measuring the pollutant of interest more directly will accomplish several important and advantageous outcomes. First, improved monitoring will improve verification of compliance and assurance of the intended emissions reductions. Second, improved monitoring can provide additional emissions reductions through quicker detection and correction of control measure problems. Third, improved monitoring can improve operating efficiencies that often result in cost savings to the facility exceeding the cost of the monitoring. We will continue to evaluate the effects of improved monitoring on emissions reductions and ways to quantify the benefits associated with improved monitoring.

We intend to move forward with developing and providing additional technical and informational materials regarding technologies constituting improved monitoring and for developing regulations with improved monitoring. These materials may also include guidance and tools for establishing emissions reductions credits and the economic benefits associated with improved monitoring. As noted in section L above, we also reaffirm our policy that effective regulations must include certain elements that define applicable emissions limitations, the testing and monitoring requirements, and compliance, reporting, and corrective action obligations.

c. Comments and Responses

We expected to receive practical advice concerning improved $PM_{2.5}$ source emissions monitoring methods and field-tested examples. Instead, commenters focused on (1) critiquing PM CEMS technology (2) insisting that improving monitoring changes stringency of existing rules and requires rulemaking, and (3) critiquing the theoretical study linking emissions reductions with improved monitoring.

1. Currently Available PM CEMS for Monitoring Direct $PM_{2.5}$ Emissions

Comment: Commenters noted that because currently available PM CEMS measure filterable PM at stack conditions or at other elevated temperatures, the instruments do not measure the condensable portion of $PM_{2.5}$.

Response: We agree with this comment relative to PM CEMS in use to date and the ability to detect condensable PM. PM CEMS as applied today can be calibrated to measure filterable $PM_{2.5}$ emissions with very good sensitivity and repeatability. Note

that we are aware of a number of PM CEMS vendors developing devices relying on much the same technology but modified to measure condensable PM. Further, we are aware of at least one manufacturer offering a PM CEMS applicable to stationary sources that also complies with ASTM requirements for mobile source emissions monitoring. We also believe that monitoring for filterable $PM_{2.5}$ will be as important in some cases as monitoring for condensable PM and that PM CEMS in use today are markedly better at monitoring PM emissions than other frequently used monitoring approaches.

We realize that PM CEMS represent just one of a range of monitoring options that constitute improvements over the current monitoring. For instance, we believe that improved monitoring would include replacing current periodic VE measurements or daily recording of pressure drop of fabric filters with continuous bag leak detectors. We know of projects (e.g., ASTM committee work) for continuing the development of optical, as well as electromagnetic, monitoring tools to increase sensitivity and cost-effectiveness. Such monitoring would increase monitoring frequency and would yield data much more closely related to and more sensitive to control device operation than most currently applied monitoring. To the extent that condensable PM control is critical in implementing a regulation, we believe that monitoring must address that need. We will continue to collect and also provide information on source monitoring approaches that are improvements over current methods in both frequency and representativeness relative to implementing $PM_{2.5}$ emissions control strategies.

2. Status of Guidance Relative to Regulations

Comment: A significant majority of commenters suggested that improving monitoring in an existing regulation increases its stringency and requires notice and comment rulemaking, not guidance. Just one commenter suggested guidance could be developed and used.

Response: There are two aspects to the comments on this issue. One is whether improved monitoring would change source operations. We agree with the commenters that increasing the frequency of data collection or providing data more directly related to the pollutant of concern with improved monitoring could result in changes in how a facility is operated relative to compliance. We disagree with commenters that such changes in process operation resulting from improved monitoring constitute an increase in a regulation's stringency with respect to compliance. First, as mentioned in the preamble to the Credible Evidence rule (62 FR 8326, February 24, 1997), an emissions standard's required stringency is unaffected by the frequency of monitoring given no decrease in averaging time or emissions limitation. Secondly, data from improved monitoring will provide a facility operator better information on control measure performance more quickly and allow for reducing the duration and the number of periods that may lead to compliance problems. Reducing the duration of excess emissions periods, for example, with improved monitoring is not an increase in regulatory stringency but a decrease in enforcement liability.

The second aspect to the comment is questioning whether we can issue technical information about improved monitoring as guidance without applying it to a **Federal Register** notice and comment process. We disagree with commenters who believe that our developing and disseminating technical resource information is limited to notice and comment rulemaking. We note that making technical and other information materials available to the public, states, and industry is an important Agency function. There are many examples of the Agency dispensing such information including the Monitoring Knowledge Base (*http://cfpub.epa.gov/mkb/*) that provides just such information on improved monitoring. On the other hand, we agree with commenters that any significant change to an existing regulation, including the addition of new monitoring requirements, would be subject to notice and comment rulemaking. To the extent that States determine the need for changing existing or developing new regulations, public notice and comment rulemaking is appropriate. Our role in developing technical resources and information informing the states in developing those revised or new regulations does not require, nor should be subject to the rulemaking process. In that light, we recognize the value in obtaining and responding to public comments and suggestions on informative technical materials. Further, we believe rulemaking is not necessarily required for source owners or operators who volunteer to participate in an optional improved monitoring program, such as the one mentioned in the proposal. That program seeks to provide SIP credits to States where source owners or operators agree to improve their PM monitoring approaches. We plan on continuing to prepare and offer non-regulatory incentives for source owners and operators who volunteer to improve existing monitoring.

3. Study of Improved Monitoring-Induced Emissions Reductions

Comment: Commenters recommended that the proposal's theoretical study showing PM emissions reductions from the use of improved monitoring needs to be validated with field data.

Response: We agree with commenters that one should base any costs and benefits findings as well as validating the approach on available data. To the extent that this applies to assessing the benefits of emissions reductions achieved through improved monitoring, we requested that commenters provide data or leads to other information or to other alternatives that show how improved monitoring yields emissions reductions and ways to quantify possible PM credits for SIPs. In fact, we are disappointed that commenters failed to provide these data or examples of other approaches. As resources allow, we will investigate opportunities for field validation of the theoretical study, as well as other means to offer incentives for use of improved monitoring.

N. Guidance Specific to Tribes

a. Background

The proposal set forth guidance for Tribes regarding various aspects of air quality management, and this guidance remains largely the same as described in the section below.

b. Final Rule

The 1998 Tribal Authority Rule (TAR) (40 CFR part 49), which implements section 301(d) of the CAA, gives Tribes the option of developing tribal implementation plans (TIPs). Specifically, the TAR provides for the Tribes to be treated in the same manner as a State in implementing sections of the CAA. However, Tribes are not required to develop implementation plans. The EPA determined in the TAR that it was inappropriate to treat Tribes in a manner similar to a State with regard to specific plan submittal and implementation deadlines for NAAQS-related requirements, including, but not limited to, such deadlines in CAA sections 110(a)(1), 172(a)(2), 182, 187, and 191. (Add footnote) See 40 CFR 49.4(a). In addition, EPA determined it was not appropriate to treat tribes similarly to states with respect to provisions of the CAA requiring as a condition of program approval the demonstration of criminal enforcement

authority or providing for the delegation of such criminal enforcement authority. See 40 CFR 49.4(g). To the extent a tribe is precluded from asserting criminal enforcement authority, the Federal government will exercise primary criminal enforcement responsibility. See 40 CFR 49.8. In such circumstances, tribes seeking approval for CAA programs provide potential investigative leads to an appropriate federal enforcement agency. (end footnote)

If a Tribe elects to do a TIP, we will work with the Tribe to develop an appropriate schedule which meets the needs of the Tribe, and which does not interfere with the attainment of the NAAQS in other jurisdictions. The Tribe developing a TIP can work with the EPA Regional Office on the appropriateness of addressing RFP and other substantive SIP requirements that may or may not be appropriate for the Tribe's situation.

The TAR indicates that EPA is ultimately responsible for implementing CAA programs in Indian country, as necessary and appropriate, if Tribes choose not to implement those provisions. For example, an unhealthy air quality situation in Indian country may require EPA to develop a FIP to reduce emissions from sources on the reservation. In such a situation, EPA, in consultation with the Tribe and in consideration of their needs, would work to ensure that the NAAQS are met as expeditiously as practicable. Likewise, if we determine that sources in Indian country could interfere with a larger nonattainment area meeting the NAAQS by its attainment date, we would develop a FIP for those sources in consultation with the Tribe, as necessary or appropriate.

The TAR also provides flexibility for the Tribe in the preparation of a TIP to address the NAAQS. If a Tribe elects to develop a TIP, the TAR offers flexibility to Tribes to identify and implement on a Tribe-by-Tribe, case-by-case basis only those CAA programs or program elements needed to address their specific air quality problems. In the proposed Tribal rule, we described this flexible implementation approach as a modular approach. Each Tribe may evaluate the particular activities, including potential sources of air pollution within the exterior boundaries of its reservation (or within non-reservation areas for which it has demonstrated jurisdiction), which cause or contribute to its air pollution problem. A Tribe may adopt measures for controlling those sources of $PM_{2.5}$-related emissions, as long as the elements of the TIP are reasonably severable from the package of elements that can be included in a whole TIP. A TIP must include regulations designed to solve specific air quality problems for which the Tribe is seeking EPA approval, as well as a demonstration that the Tribal air agency has the authority from the Tribal government to develop and run their program, the capability to enforce their rules, and the resources to implement the program they adopt. In addition, the Tribe must receive an eligibility determination from EPA to be treated in the same manner as a State and to receive authorization from EPA to run a CAA program.

The EPA would review and approve, where appropriate, these partial TIPs as one step of an overall air quality plan to attain the NAAQS. A Tribe may step in later to add other elements to the plan, or EPA may step in to fill gaps in the air quality plan as necessary or appropriate. In approving a TIP, we would evaluate whether the plan interferes with the overall air quality plan for an area when Tribal lands are part of a multi-jurisdictional area. Because many of the nonattainment areas will include multiple jurisdictions, and in some cases both Tribal and State jurisdictions, it is important for the Tribes and the States to work together to coordinate their planning efforts. States need to incorporate Tribal emissions in their base emission inventories if Indian country is part of an attainment or nonattainment area. Tribes and States need to coordinate their planning activities as appropriate to ensure that neither is adversely affecting attainment of the NAAQS in the area as a whole.

c. Comments and Responses

No public comments were received on this section.

O. Enforcement and Compliance

a. Background

The proposed rule included a discussion of the specific requirements that must be addressed in order for SIP regulations to be enforceable.

b. Final Rule

The final rule includes similar guidance on enforceable SIP regulations, with some additional discussion about specific elements that must be addressed regarding compliance testing and compliance monitoring. (Note that enforceable SIP regulations may address these key elements in different ways depending on the type of source category being regulated.)

In general, for a SIP regulation to be enforceable, it must clearly spell out which sources or source types are subject to its requirements and what its requirements (e.g., emission limits, work practices, etc.) are. The regulation also needs to specify the time frames within which these requirements must be met, and must definitively state recordkeeping and monitoring requirements appropriate to the type of sources being regulated. The recordkeeping and monitoring requirements must be sufficient to enable the State or EPA to determine whether the source is complying with the emission limit on a continuous basis. An enforceable regulation must also contain test procedures in order to determine whether sources are in compliance.

Complete and effective regulations that ensure compliance with an applicable emissions limit must include requirements for both performance testing of emissions and ongoing monitoring of the compliance performance of control measures. SIP regulations must include the following critical elements of regulatory compliance testing:

- Indicator(s) of compliance—the pollutant or pollutants of interest (e.g., filterable $PM_{2.5}$ plus condensable $PM_{2.5}$) and the applicable measurable units for expressing compliance (e.g., ng/J of heat input, lb/hr);
- Test method—reference to a specific EPA or other published set of sample collection and analytical procedures, equipment design and performance criteria, and the calculations providing data in units of the indicator of compliance (see section II.L. below for descriptions of available and potential improved test methods);
- Averaging time—the minimum length of each required test run and the requirement to average the results of the test runs (e.g., three runs) representing a specified period of time (e.g., 8 hours); and
- Frequency—the maximum time between conduct of emissions or performance tests (e.g., within 30 days of facility start-up and once each successive quarter, every 6-month period, yearly).

In order to be complete with regard to compliance monitoring provisions, SIP regulations must include the following critical elements:

- Indicator(s) of performance—the parameter or parameters measured or observed for demonstrating proper operation of the pollution control measures or compliance with the applicable emissions limitation or standard. Indicators of performance may include direct or predicted emissions measurements, process or control device (and capture system) operational

parametric values that correspond to compliance with efficiency or emissions limits, and recorded findings of verification of work practice activities, raw material or fuels pollutant content, or design characteristics. Indicators may be expressed as a single maximum or minimum value, a function of process variables (e.g., within a range of pressure drops), a particular operational or work practice status (e.g., a damper position, completion of a waste recovery task), raw material or fuel pollutant content, or an interdependency between two or more variables;

• Measurement technique—the means used to gather and record information of or about the indicators of performance. The components of the measurement technique include the detector type or analytical method, location and installation specifications, inspection procedures, and quality assurance and quality control measures. Examples of measurement approaches include continuous emissions monitoring systems, continuous opacity monitoring systems, continuous parametric monitoring systems, performance testing, vendor or laboratory analytical data, and manual inspections and data collection that include making records of process conditions, raw materials or fuel specifications, or work practices;

• Monitoring frequency—the number of times to obtain and record monitoring data over a specified time interval. Examples of monitoring frequencies include at least one data value every 15 minutes for continuous emissions or parametric monitoring systems, at least every 10 seconds for continuous opacity monitoring systems, upon receipt or application of raw materials or fuel to the process, and at least once per operating day (or week, month, etc.) for performance testing, work practice verification, or equipment design inspections; and

• Averaging time—the period over which to average and use data to verify compliance with the emissions limitation or standard or proper operation of the pollution control measure. Examples of averaging time include a 3-hour average in units of the emissions limitation, a 30-day rolling average emissions value, a daily average of a control device operational parametric range, periodic (e.g., monthly, annual) average of raw materials or fuel pollutant content, and an instantaneous alarm.

These regulatory elements are essential for effective implementation of the rules and clear and enforceable applicable requirements. We believe that approval of regulations implementing the SIPs must ensure that these critical elements are present and clearly defined to be approvable. We reiterate that the compliance obligations, including emissions limits and other applicable requirements, must be representative of and accountable to the assumptions used in the SIP demonstration. This accountability includes the ability to transfer the applicable regulatory requirements to an operating permit subject to EPA and public review.

Under the Title V regulations, sources have an obligation to include in their Title V permit applications all emissions for which the source is major and all emissions of regulated air pollutants. The definition of regulated air pollutant in 40 CFR 70.2 includes any pollutant for which a NAAQS has been promulgated, which would include both PM_{10} and $PM_{2.5}$. To date, some permitted entities have been using PM_{10} emissions as a surrogate for $PM_{2.5}$ emissions. Upon promulgation of this rule, EPA will no longer accept the use of PM_{10} as a surrogate for $PM_{2.5}$. Thus, sources will be required to include their $PM_{2.5}$ emissions in their Title V permit applications, in any corrections or supplements to these applications, and in applications submitted upon modification and renewal.[52] The degree of quantification of $PM_{2.5}$ emissions required will depend on the types of determinations that a permitting authority needs to address for a particular source, the requirements of title V, and the informational needs and requirements of the particular State in question. Sources must continue to describe their PM_{10} emissions in their applications as indicated above because the original PM_{10} NAAQS remains in effect.

c. Comments and Responses

Comment: One commenter disagreed with language in the preamble to the proposal regarding Title V permitting requirements and the requirement to include various emissions information in title V permit applications. As described in 40 CFR 70.5(c)(3)(i) and 71.5(c)(3)(i), sources are required to include in their permit applications all emissions for which the source is major and all emissions of regulated air pollutants. In the preamble to the proposal, the EPA stated that in the past some permitted entities have been using PM_{10} emissions as a surrogate for $PM_{2.5}$ emissions in permit applications, or in corrections or supplements to applications. The EPA stated that upon promulgation of this rule, the EPA will no longer accept the use of PM_{10} as a surrogate for $PM_{2.5}$.

The commenter disagreed with language in the proposal stating that sources would be required to detail or quantify $PM_{2.5}$ emissions in permit applications, or in corrections or supplements to applications. The commenter asserts that the inclusion of $PM_{2.5}$ emissions information is required in a Title V permit application only if there is an applicable requirement in existence for which the source's applicability is in question and cited to various examples from the memorandum entitled ''White Paper for Streamlined Development of Part 70 Permit Applications,'' from Lydia N. Wegman, Deputy Director, Office of Air Quality Planning and Standards, to Air Division Directors, Regions I–X, dated July 10, 1995.

Response: The commenter is concerned that as a result of this rule all applications (including initial, modification, and renewal applications) will need to include a quantification of $PM_{2.5}$ emissions, and that a State will request that every source supplement or correct any existing title V application in order to provide an estimation of $PM_{2.5}$ emissions at the source.

The EPA is not implying that this is the case. The degree of quantification of $PM_{2.5}$ emissions required in an application (including an initial, modification, or renewal application), or in a correction or supplement to an existing application, depends on the types of determinations that a permitting authority needs to address for a particular source, the requirements of title V, and the informational needs and requirements of the particular State in question. For example, if a source which emits $PM_{2.5}$ emissions has submitted a title V application, but a draft permit has not yet been issued, then the source is required to submit information relative to the quantification of its $PM_{2.5}$ emissions if such information is needed or requested and it has not previously submitted such information. See 40 CFR 70.5(b) and 71.5(b).

Circumstances necessitating the quantification of $PM_{2.5}$ emissions and the submittal of this information include: (1) Determining all of the pollutants for which a source is major; (2) determining whether an applicable requirement or program applies, e.g., determining the applicability of a SIP requirement or a PSD or nonattainment NSR program, etc.; or (3) determining what fees a source owes a permitting

[52] See 40 CFR 70.5(c)(3)(i), 70.5(b), and 70.7(a)(1)(i); 40 CFR 71.5(c)(3)(i), 71.5(b), and 71.7(a)(1)(i).

authority as a result of considering $PM_{2.5}$ emissions.

In all circumstances, however, a State may require that a source quantify its $PM_{2.5}$ emissions information in an application, supplement, or correction, even if it is not needed for the particular determination at issue. The State, for example, may choose to obtain this information for air quality planning purposes, developing emission inventories, or for other purposes related to its air quality management goals. Requesting such emissions information is an option for any title V permitting authority.

The ''White Paper for Streamlined Development of Part 70 Permit Applications,'' referenced by the commenter, was a confirmation of EPA policy with respect to the fact that the specificity of emissions quantification can vary significantly, depending on the circumstances of a particular source. It is also important to note that this guidance document is a statement regarding the range of discretion available to permitting authorities in implementing the emissions quantification requirement, not a restriction of that discretion to minimum practices. Thus, States can implement this guidance document at their option, either in part or in its entirety.

In summary, the purpose of the statements made in the preamble to the proposal was to notify sources that as of the promulgation of this final rule, the EPA will no longer accept the use of PM_{10} emissions information as a surrogate for $PM_{2.5}$ emissions information [53] given that both pollutants are regulated by a National Ambient Air Quality Standard and therefore are considered regulated air pollutants. See the definition of regulated air pollutant in 40 CFR 70.2 and 71.2.[54] The degree of quantification of $PM_{2.5}$ emissions now required in an application (including an initial, modification, or renewal application), or provided in a correction or supplement to an existing application, will depend on the types of determinations that a permitting authority needs to address for a particular source, the requirements of title V, and the informational needs and requirements of the particular State in question.

P. Emergency Episodes

a. Background

In the proposal, we noted that subpart H of 40 CFR part 51 specifies requirements for SIPs to address emergency air pollution episodes and for preventing air pollutant levels from reaching levels determined to cause significant harm to the health of persons. We noted that we anticipate proposing a separate rulemaking in the future to update portions of that rule. The preamble to the proposal

b. Final Rule

We have not yet proposed any rule revision related to emergency episodes.

c. Comments and Responses

We received no comments on this section of the proposal.

Q. Ambient Monitoring

a. Background

Ambient air quality monitoring for $PM_{2.5}$ plays an important role in identifying areas violating the NAAQS, control strategy development, and tracking progress to attainment. We indicated in the proposal that States are required to monitor $PM_{2.5}$ mass concentrations using Federal Reference Method devices to determine compliance with the NAAQS.[55] We did not propose any revisions to current ambient monitoring requirements listed in 40 CFR part 58. Currently, there are more than 1200 FRM monitors located across the country. States will need to maintain monitors in designated nonattainment areas in order to track progress toward attainment and ultimately determine whether the area has attained the $PM_{2.5}$ standards.

In addition to the FRM network, EPA and the States have also deployed more than 250 speciation monitoring sites around the country to sample for chemical composition of $PM_{2.5}$. The data provided from these speciation monitors are invaluable in identifying contributing source categories and developing control strategies to reach attainment. Source apportionment and other receptor modeling techniques rely on the detailed data on species, ions, and other compounds obtained from chemical analysis. Analyses of rural versus urban sites to identify which $PM_{2.5}$ components comprise the ''urban excess'' (urban minus rural levels) portion of $PM_{2.5}$ mass also rely on data from speciation monitors. The EPA encourages states to expand their data analysis efforts using the wealth of information provided from the speciation monitoring network.

b. Final Rule

There is no change from the proposal. We are not promulgating any additional monitoring requirements as part of this rulemaking. Revised monitoring regulations were issued in 2006 along with the revised PM NAAQS.

c. Comments and Responses

There were no comments on this section.

III. Statutory and Executive Order Reviews

A. Executive Order 12866: Regulatory Planning and Review

Under section 3(f)(1) of Executive Order (EO) 12866 (58 FR 51735, October 4, 1993), this action is an ''economically significant regulatory action.'' Implementation of the $PM_{2.5}$ NAAQS is likely to have an annual effect on the economy of $100 million or more. Accordingly, EPA submitted this action to the Office of Management and Budget (OMB) for review under EO 12866 and any changes made in response to OMB recommendations have been documented in the docket for this action. For clarity, we note that the estimated costs and benefits of implementing the 1997 $PM_{2.5}$ NAAQS are not created by this rule, because the Clean Air Act requires state implementation of the 1997 $PM_{2.5}$ standards (through state development of plans with enforceable requirements for sources) on a statutory timetable regardless of whether EPA issues this rule interpreting the statutory requirements. The rule reflects the statutory requirements.

As part of the ''Regulatory Impact Analysis for Particulate Matter National Ambient Air Quality Standards (September 2006),'' EPA prepared an assessment of the estimated costs and benefits associated with attaining the 1997 $PM_{2.5}$ NAAQS in 2015, incremental to currently promulgated federal and state programs including for example the Clean Air Interstate Rule, the Nonroad Diesel Rule, and other programs. This analysis is included as Appendix A of the report and is available in the docket for this action and on EPA's Web site at: *http://www.epa.gov/ttn/ecas/regdata/RIAs/Appendix%20A—2015%20Analysis.pdf.* This illustrative

[53] For background information on issues surrounding implementation of the $PM_{2.5}$ NAAQS, see the EPA memo entitled ''Implementation of New Source Review Requirements in $PM_{2.5}$ Nonattainment Areas,'' from Stephen D. Page, Director, Office of Air Quality Planning and Standards, to Regional Air Directors, Regions I–X, dated April 5, 2005.

[54] For background information on regulated air pollutants, see the EPA memo entitled ''Definition of Regulated Air Pollutant for Purposes of Title V,'' from Lydia N. Wegman, Deputy Director, Office of Air Quality Planning and Standards, to Air Division Directors, Regions I–X, dated April 26, 1993.

[55] The $PM_{2.5}$ monitoring regulations are located at 40 CFR part 58.

analysis finds that the estimated monetized benefits of attaining the 1997 standards in 2015 are between $43 billion and $97 billion annually, and the estimated monetized costs are $6.7 billion annually. The RIA states: ''Note that because this analysis was intended to compare costs and benefits of attaining alternative standards by fixed dates, it did not attempt to identify for each designated $PM_{2.5}$ area measures that may be needed to meet subpart 1 Clean Air Act requirements, such as reasonably available measures and attainment as expeditiously as practicable. It is expected that additional costs and benefits will begin to accrue in earlier years as states comply with these requirements.'' (RIA, p. 1–4)

B. Paperwork Reduction Act

The information collection requirements in this rule have been submitted for approval to the Office of Management and Budget (OMB) under the *Paperwork Reduction Act,* 44 U.S.C. 3501 *et seq.* In a separate **Federal Register** notice published today, EPA is requesting comment on the information collection requirements of this rule. The information collection requirements are not enforceable until OMB approves them.

The data collected from the State or local air agency respondents will include the required SIP elements prescribed in CAA sections 110 and part D, subpart 1 of title I for Implementation plans and the requirements in this Implementation Rule (40 CFR 51.1000–51.1012). The $PM_{2.5}$ SIP will contain rules and other requirements designed to achieve the NAAQS by the deadlines established under the CAA, and it also contains a demonstration that the State's requirements will in fact result in attainment. The SIP must meet the requirements in subpart 1 to adopt RACM, RACT, and provide for RFP toward attainment for the period prior to the area's attainment date.

The Agency anticipates additional administrative burden during the 3 year period of the ICR for State governments and the Agency of 630,000 hours and 69,300 hours, respectively. Fifty percent of the hours are expended in the first year with the remainder evenly divided between the second and third years of the ICR period. Tribes are not required to conduct attainment demonstrations or submit the RFP, RACT, or RACM requirements.

The present value of the total additional costs for State government respondents is estimated at $33.4 million for the 3 year period. On an equivalent annual basis that is $12.7 million per year during the 3 year period of the ICR. The present value of the Agency administrative cost burden is estimated at $3.7 million dollars for the 3 year period. This is equivalent to an equal annual stream of costs of $1.4 million per year during the three year period. Burden means the total time, effort, or financial resources expended by persons to generate, maintain, retain, or disclose or provide information to or for a Federal agency. This includes the time needed to review instructions; develop, acquire, install, and utilize technology and systems for the purposes of collecting, validating, and verifying information, processing and maintaining information, and disclosing and providing information; adjust the existing ways to comply with any previously applicable instructions and requirements; train personnel to be able to respond to a collection of information; search data sources; complete and review the collection of information; and transmit or otherwise disclose the information.

An agency may not conduct or sponsor, and a person is not required to respond to a collection of information unless it displays a currently valid OMB control number. The OMB control numbers for EPA's regulations in 40 CFR are listed in 40 CFR part 9. When this ICR is approved by OMB, the Agency will publish a technical amendment to 40 CFR part 9 in the **Federal Register** to display the OMB control number for the approved information collection requirements contained in this final rule.

C. Regulatory Flexibility Act

The Regulatory Flexibility Act (RFA) generally requires an agency to prepare a regulatory flexibility analysis of any rule subject to notice and comment rulemaking requirements under the Administrative Procedure Act or any other statute unless the agency certifies that the rule will not have a significant economic impact on a substantial number of small entities. Small entities include small businesses, small organizations, and small governmental jurisdictions.

For purposes of assessing the impacts of this final action on small entities, small entity is defined as: (1) A small business as defined by the Small Business Administration's (SBA) regulations at 13 CFR 121.201; (2) a small governmental jurisdiction that is a government of a city, county, town, school district, or special district with a population of less than 50,000; or (3) a small organization that is any not-for-profit enterprise that is independently owned and operated and is not dominant in its field.

After considering the economic impacts of this final rule on small entities, I certify that this action will not have a significant economic impact on a substantial number of small entities and it is not necessary to prepare a regulatory flexibility analysis in conjunction with this final rule. The final rule governing SIPs will not directly impose any requirements on small entities. Rather, this rule interprets the obligations established in the CAA for States to submit implementation plans in order to attain the $PM_{2.5}$ NAAQS.

D. Unfunded Mandates Reform Act

Title II of the Unfunded Mandates Reform Act of 1995 (UMRA), Public Law 104–4, establishes requirements for Federal agencies to assess the effects of their regulatory actions on State, local, and Tribal governments and the private sector. Under section 202 of the UMRA, EPA generally must prepare a written statement, including a cost-benefit analysis, for proposed and final rules with ''Federal mandates'' that may result in expenditures to State, local, and tribal governments, in the aggregate, or to the private sector, of $100 million or more in any 1 year. Before promulgating an EPA rule for which a written statement is needed, EPA is required by section 205 of the UMRA to identify and consider a reasonable number of regulatory alternatives, and adopt the least costly, most cost-effective or least burdensome alternative that achieves the objectives of the rule. The provisions of section 205 do not apply when they are inconsistent with applicable law. Moreover, section 205 allows EPA to adopt an alternative other than the least costly, most cost-effective or least burdensome alternative if the Administrator publishes with the final rule an explanation why that alternative was not adopted. Before EPA establishes any regulatory requirements that may significantly or uniquely affect small governments, including Tribal governments, it must have developed under section 203 of the UMRA a small government agency plan. The plan must provide for notifying potentially affected small governments, enabling officials of affected small governments to have meaningful and timely input in the development of EPA regulatory proposals with significant Federal intergovernmental mandates, and informing, educating, and advising small governments on compliance with the regulatory requirements.

This rule contains no Federal mandate that may result in expenditures

of $100 million or more for State, local, and Tribal governments, in the aggregate, or the private sector in any 1 year. The estimated administrative burden hours and costs associated with implementing the $PM_{2.5}$ NAAQS are estimated in the ICR for this rule. The estimated costs presented there for States totals $33.4 million for a three-year period. Thus, this rule is not subject to the requirements of section 202 and 205 of the UMRA. The EPA consulted with governmental entities affected by this rule and has determined that this rule contains no regulatory requirements that may significantly or uniquely affect small governments, including Tribal governments.

The CAA imposes the obligation for States to submit SIPs to implement the $PM_{2.5}$ NAAQS. In this rule, EPA is merely providing an interpretation of those requirements. However, even if this rule did establish an independent requirement for States to submit SIPs, it is questionable whether a requirement to submit a SIP revision would constitute a Federal mandate in any case. The obligation for a State to submit a SIP that arises out of section 110 and section 172 (part D) of the CAA is not legally enforceable by a court of law, and at most is a condition for continued receipt of highway funds. Therefore, it is possible to view an action requiring such a submittal as not creating any enforceable duty within the meaning of section 421(5)(9a)(I) of UMRA (2 U.S.C. 658(a)(I)). Even if it did, the duty could be viewed as falling within the exception for a condition of Federal assistance under section 421(5)(a)(i)(I) of UMRA (2 U.S.C. 658(5)(a)(i)(I)).

E. Executive Order 13132: Federalism

Executive Order 13132, entitled ''Federalism'' (64 FR 43255, August 10, 1999), requires EPA to develop an accountable process to ensure ''meaningful and timely input by State and local officials in the development of regulatory policies that have Federalism implications.'' ''Policies that have Federalism implications'' is defined in the Executive Order to include regulations that have ''substantial direct effects on the States, on the relationship between the national government and the States, or on the distribution of power and responsibilities among the various levels of government.''

At the time of proposal, EPA concluded that the proposed rule would not have any federalism implications. The EPA stated that the proposed rule would not have substantial direct effects on the States, on the relationship between the national government and the States, or on the distribution of power and responsibilities among the various levels of government, as specified in Executive Order 13132. The CAA establishes the scheme whereby States take the lead in developing plans to meet the NAAQS. This rule clarifies the statutory obligations of States in implementing the $PM_{2.5}$ NAAQS. However, EPA recognized that States would have a substantial interest in this rule and any corresponding revisions to associated SIP requirements.

Therefore, in the spirit of Executive Order 13132, and consistent with EPA policy to promote communications between EPA and State and local governments, EPA held a number of calls with representatives of State and local air pollution control agencies and hosted a public hearing in Washington, DC in November 2005. The EPA considered the comments from State and local governments in developing the final rule.

EPA concludes that this final rule does not have federalism implications, for the reasons proposed. The final rule will not modify the relationship of the States and EPA for purposes of developing programs to implement the NAAQS. As noted above in section D on UMRA, this rule does not impose significant costs on State and local governments. (EPA estimates the costs to States to implement the $PM_{2.5}$ NAAQS to be $33.4 million.) Thus, Executive Order 13132 does not apply to this rule.

F. Executive Order 13175: Consultation and Coordination With Indian Tribal Governments

Executive Order 13175, entitled ''Consultation and Coordination with Indian Tribal Governments'' (65 FR 67249, November 9, 2000), requires EPA to develop an accountable process to ensure ''meaningful and timely input by Tribal officials in the development of regulatory policies that have Tribal implications.'' This final rule does not have ''Tribal implications'' as defined in Executive Order 13175. This rule concerns the requirements for State and tribal implementation plans for attaining the $PM_{2.5}$ air quality standards. The CAA provides for States to develop plans to regulate emissions of air pollutants within their jurisdictions. The Tribal Air Rule (TAR) under the CAA gives Tribes the opportunity to develop and implement CAA programs such as programs to attain and maintain the $PM_{2.5}$ NAAQS, but it leaves to the discretion of the Tribe the decision of whether to develop these programs and which programs, or appropriate elements of a program, they will adopt.

Although Executive Order 13175 does not apply to this rule, EPA did reach out to Tribal leaders and environmental staff in developing this rule. From 2001–2004, the EPA supported a National Designations Workgroup to provide a forum for tribal professionals to give input to the designations process. In 2006, EPA supported a national ''Tribal Air call'' which provides an open forum for all Tribes to voice concerns to EPA about the NAAQS implementation process, including the $PM_{2.5}$ NAAQS. In these meetings, EPA briefed call participants and Tribal environmental professionals gave input as the rule was under development. Furthermore, in December 2005, EPA sent individualized letters to all federally recognized Tribes about the proposal to give Tribal leaders the opportunity for consultation.

This final rule does not have Tribal implications as defined by Executive Order 13175. It does not have a substantial direct effect on one or more Indian Tribes, since no Tribe has implemented a CAA program to attain the $PM_{2.5}$ NAAQS at this time. The EPA notes that even if a Tribe were implementing such a plan at this time, while the rule might have Tribal implications with respect to that Tribe, it would not impose substantial direct costs upon it, nor would it preempt Tribal law.

Furthermore, this rule does not affect the relationship or distribution of power and responsibilities between the Federal government and Indian Tribes. The CAA and the TAR establish the relationship of the Federal government and Tribes in developing plans to attain the NAAQS, and this rule does nothing to modify that relationship. As this rule does not have Tribal implications, Executive Order 13175 does not apply.

G. Executive Order 13045: Protection of Children From Environmental Health and Safety Risks

EO 13045, ''Protection of Children from Environmental Health and Safety Risks,'' (62 FR 19885, April 23, 1997) applies to any rule that (1) Is determined to be ''economically significant'' as defined under Executive Order 12866, and (2) concerns an environmental health or safety risk that EPA has reason to believe may have disproportionate effect on children. If the regulatory action meets both criteria, the Agency must evaluate the environmental health or safety effects of the planned rule on children, and explain why the planned regulation is preferable to other potentially effective and reasonably feasible alternatives considered by the Agency. This final

rule is subject to EO 13045 because it is economically significant as defined in EO 12866, and we believe that the environmental health risk addressed by this action may have a disproportionate effect on children. This rule implements a previously promulgated health-based Federal standard—the $PM_{2.5}$ NAAQS [56]. The NAAQS constitute uniform, national standards for PM pollution; these standards are designed to protect public health with an adequate margin of safety, as required by CAA section 109. However, the protection offered by these standards may be especially important for children because children, along with other sensitive population subgroups such as the elderly and people with existing heart or lung disease, are potentially susceptible to health effects resulting from PM exposure. Because children are considered a potentially susceptible population, we have carefully evaluated the environmental health effects of exposure to PM pollution among children. These effects and the size of the population affected are summarized in section 9.2.4 of the Criteria Document and section 3.5 of the Staff Paper.

H. Executive Order 13211: Actions That Significantly Affect Energy Supply, Distribution, or Use

This final rule is not a ''significant energy action'' as defined in Executive Order 13211, ''Actions That Significantly Affect Energy Supply, Distribution, or Use,'' (66 FR 28355, May 22, 2001) because it is not likely to have a significant adverse effect on the supply, distribution, or use of energy. This rule is not a ''significant energy action,'' because it does not establish requirements that directly affect the general public and the public and private sectors, but, rather, interprets the statutory requirements that apply to States in preparing their SIPs. The SIPs themselves will likely establish requirements that directly affect the general public, and the public and private sectors.

I. National Technology Transfer Advancement Act

Section 12(d) of the National Technology Transfer Advancement Act of 1995 (''NTTAA''), Public Law No. 104–113, section 12(d) (15 U.S.C. 272 note) directs EPA to use voluntary consensus standards (VCS) in its regulatory activities unless to do so would be inconsistent with applicable law or otherwise impractical. Voluntary consensus standards are technical standards (e.g., materials specifications, test methods, sampling procedures, and business practices) that are developed or adopted by VCS bodies. The NTTAA directs EPA to provide Congress, through OMB, explanations when the Agency decides not to use available and applicable VCS.

This final rulemaking does not involve technical standards. Therefore, EPA is not considering the use of any VCS. The EPA will encourage the States and Tribes to consider the use of such standards, where appropriate, in the development of their implementation plans.

J. Executive Order 12898: Federal Actions To Address Environmental Justice in Minority Populations and Low-Income Populations

EO 12898 (59 FR 7629 (Feb. 16, 1994) establishes Federal executive policy on environmental justice. Its main provision directs Federal agencies, to the greatest extent practicable and permitted by law, to make environmental justice part of their mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of their programs, policies and activities on minority populations and low-income populations in the United States.

The EPA has determined that the final rule should not have disproportionately high and adverse human health or environmental effects on minority or low-income populations because it increases the level of environmental protection for all affected populations without having any disproportionately high and adverse human health or environmental effects on any population, including any minority or low-income population. The health and environmental risks associated with fine particles were considered in the establishment of the $PM_{2.5}$ NAAQS. The level is designed to be protective with an adequate margin of safety. This final rule provides a framework for improving environmental quality and reducing health risks for areas that may be designated nonattainment.

K. Congressional Review Act

The Congressional Review Act, 5 U.S.C. 801 et seq., as added by the Small Business Regulatory Enforcement Fairness Act of 1996, generally provides that before a rule may take effect, the agency promulgating the rule must submit a rule report, which includes a copy of the rule, to each House of the Congress and to the Comptroller General of the United States. The EPA will submit a report containing the rule and other required information to the U.S. Senate, the U.S. House of Representatives, and the Comptroller General of the United States prior to publication of the rule in the **Federal Register**. A Major rule cannot take effect until 60 days after it is published in the **Federal Register**. This action is a ''major rule'' as defined by 5 U.S.C. 804(2). This rule will be effective June 25, 2007.

L. Petitions for Judicial Review

Under section 307(b)(1) of the Act, petitions for judicial review of this action must be filed in the United States Court of Appeals for the District of Columbia Circuit by June 25, 2007. Filing a petition for reconsideration by the Administrator of this final rule does not affect the finality of this rule for the purposes of judicial review nor does it extend the time within which a petition for judicial review may be filed, and shall not postpone the effectiveness of such rule or action. This action may not be challenged later in proceedings to enforce its requirements. See Act section 307(b)(2).

M. Judicial Review

Under sections 307(d)(1)(E) and 307(d)(1)(V) of the CAA, the Administrator determines that this action is subject to the provisions of section 307(d). Section 307(d)(1)(V) provides that the provisions of section 307(d) apply to ''such other actions as the Administrator may determine.'' While the Administrator did not make this determination earlier, the Administrator believes that all of the procedural requirements, e.g., docketing, hearing and comment periods, of section 307(d) have been complied with during the course of this rulemaking.

IV. Statutory Authority

The statutory authority for this action is provided by 42 U.S.C. 7401, 7408, 7410, 7501–7509a, and 7601(a)(1). This notice is also subject to 307(d) of the CAA (42 U.S.C. 7407(d)).

List of Subjects in 40 CFR Part 51

Administrative practice and procedure, Air pollution control, Intergovernmental relations, Nitrogen dioxide, Ozone, Particulate matter, Sulfur oxides, Transportation, Volatile organic compound.

Dated: March 29, 2007.

Stephen L. Johnson,

Administrator.

■ For the reasons set out in the preamble, title 40, chapter I of the Code

[56] *See* 62 FR 38652–38760, National Ambient Air Quality Standards for Particulate Matter, Final Rule; also 40 CFR part 50.

of Federal Regulations is amended as follows:

■ 1. The authority citation for part 51 continues to read as follows:

Authority: 23 U.S.C. 101; 42 U.S.C. 7401–7671q.

■ 2. A new Subpart Z is added to read as follows:

Subpart Z—Provisions for Implementation of $PM_{2.5}$ National Ambient Air Quality Standards

Sec.

§ 51.1000 Definitions.

The following definitions apply for purposes of this subpart. Any term not defined herein shall have the meaning as defined in 40 CFR 51.100.

Act means the Clean Air Act as codified at 42 U.S.C. 7401–7671q. (2003).

Attainment date means the date by which an area, under an approved State implementation plan, is required to attain the $PM_{2.5}$ NAAQS (based on the average of three consecutive years of ambient air quality data).

Baseline year inventory for the RFP plan is the emissions inventory for the year also used as the base year for the attainment demonstration.

Benchmark RFP plan means the reasonable further progress plan that requires generally linear emission reductions in pollutants from the baseline emissions year through the milestone inventory year.

Date of designation means the effective date of the $PM_{2.5}$ area designation as promulgated by the Administrator.

Direct $PM_{2.5}$ emissions means solid particles emitted directly from an air emissions source or activity, or gaseous emissions or liquid droplets from an air emissions source or activity which condense to form particulate matter at ambient temperatures. Direct $PM_{2.5}$ emissions include elemental carbon, directly emitted organic carbon, directly emitted sulfate, directly emitted nitrate, and other inorganic particles (including but not limited to crustal material, metals, and sea salt).

Existing control measure means any Federally enforceable national, State, or local control measure that has been approved in the SIP and that results in reductions in emissions of $PM_{2.5}$ or $PM_{2.5}$ precursors in a nonattainment area.

Full implementation inventory is the projected RFP emission inventory for the year preceding the attainment date, representing a level of emissions that demonstrates attainment.

Milestone year inventory is the projected RFP emission inventory for the applicable RFP milestone year (*i.e.* 2009 and, where applicable, 2012).

$PM_{2.5}$ NAAQS means the particulate matter national ambient air quality standards (annual and 24-hour) codified at 40 CFR 50.7.

$PM_{2.5}$ design value for a nonattainment area is the highest of the three-year average concentrations calculated for the monitors in the area, in accordance with 40 CFR part 50, appendix N.

$PM_{2.5}$ attainment plan precursor means $S0_2$ and those other $PM_{2.5}$ precursors emitted by sources in the State which the State must evaluate for emission reduction measures to be included in its $PM_{2.5}$ nonattainment area or maintenance area plan.

$PM_{2.5}$ precursor means those air pollutants other than $PM_{2.5}$ direct emissions that contribute to the formation of $PM_{2.5}$. $PM_{2.5}$ precursors include $S0_2$, NO_X, volatile organic compounds, and ammonia.

Reasonable further progress (RFP) means the incremental emissions reductions toward attainment required under sections 172(c)(2) and 171(1).

Subpart 1 means the general attainment plan requirements found in subpart 1 of part D of title I of the Act.

§ 51.1001 Applicability of part 51.

The provisions in subparts A through X of this part apply to areas for purposes of the $PM_{2.5}$ NAAQS to the extent they are not inconsistent with the provisions of this subpart.

§ 51.1002 Submittal of State implementation plan.

(a) For any area designated by EPA as nonattainment for the $PM_{2.5}$ NAAQS, the State must submit a State implementation plan satisfying the requirements of section 172 of the Act and this subpart to EPA by the date prescribed by EPA which will be no later than 3 years from the date of designation.

(b) The State must submit a plan consistent with the requirements of section 110(a)(2) of the Act unless the State already has fulfilled this obligation for the purposes of implementing the $PM_{2.5}$ NAAQS.

(c) *Pollutants contributing to fine particle concentrations.* The State implementation plan must identify and evaluate sources of $PM_{2.5}$ direct emissions and $PM_{2.5}$ attainment plan precursors in accordance with §§ 51.1009 and 51.1010. After January 1, 2011, for purposes of establishing emissions limits under 51.1009 and 51.1010, States must establish such limits taking into consideration the condensable fraction of direct $PM_{2.5}$ emissions. Prior to this date, States are not prohibited from establishing source emission limits that include the condensable fraction of direct $PM_{2.5}$.

(1) The State must address sulfur dioxide as a $PM_{2.5}$ attainment plan precursor and evaluate sources of SO_2 emissions in the State for control measures.

(2) The State must address NO_X as a $PM_{2.5}$ attainment plan precursor and evaluate sources of NO_X emissions in the State for control measures, unless the State and EPA provide an appropriate technical demonstration for a specific area showing that NO_X emissions from sources in the State do not significantly contribute to $PM_{2.5}$ concentrations in the nonattainment area.

(3) The State is not required to address VOC as a $PM_{2.5}$ attainment plan precursor and evaluate sources of VOC emissions in the State for control measures, unless:

(i) the State provides an appropriate technical demonstration for a specific area showing that VOC emissions from sources in the State significantly contribute to $PM_{2.5}$ concentrations in the nonattainment area, and such demonstration is approved by EPA; or

(ii) The EPA provides such a technical demonstration.

(4) The State is not required to address ammonia as a $PM_{2.5}$ attainment plan precursor and evaluate sources of ammonia emissions from sources in the State for control measures, unless:

(i) The State provides an appropriate technical demonstration for a specific area showing that ammonia emissions from sources in the State significantly contribute to $PM_{2.5}$ concentrations in the

nonattainment area, and such demonstration is approved by EPA; or

(ii) The EPA provides such a technical demonstration.

(5) The State must submit a demonstration to reverse any presumption in this rule for a $PM_{2.5}$ precursor with respect to a particular nonattainment area, if the administrative record related to development of its SIP shows that the presumption is not technically justified for that area.

§ 51.1003 [Reserved]

§ 51.1004 Attainment dates.

(a) Consistent with section 172(a)(2)(A) of the Act, the attainment date for an area designated nonattainment for the $PM_{2.5}$ NAAQS will be the date by which attainment can be achieved as expeditiously as practicable, but no more than five years from the date of designation. The Administrator may extend the attainment date to the extent the Administrator determines appropriate, for a period no greater than 10 years from the date of designation, considering the severity of nonattainment and the availability and feasibility of pollution control measures.

(b) In the SIP submittal for each of its nonattainment areas, the State must submit an attainment demonstration justifying its proposed attainment date. For each nonattainment area, the Administrator will approve an attainment date at the same time the Administrator approves the attainment demonstration for the area, consistent with the attainment date timing provision of section 172(a)(2)(A) and paragraph (a) of this section.

(c) Upon a determination by EPA that an area designated nonattainment for the $PM_{2.5}$ NAAQS has attained the standard, the requirements for such area to submit attainment demonstrations and associated reasonably available control measures, reasonable further progress plans, contingency measures, and other planning SIPs related to attainment of the $PM_{2.5}$ NAAQS shall be suspended until such time as: the area is redesignated to attainment, at which time the requirements no longer apply; or EPA determines that the area has violated the $PM_{2.5}$ NAAQS, at which time the area is again required to submit such plans.

§ 51.1005 One-year extensions of the attainment date.

(a) Pursuant to section 172(a)(2)(C)(ii) of the Act, a State with an area that fails to attain the $PM_{2.5}$ NAAQS by its attainment date may apply for an initial 1-year attainment date extension if the State has complied with all requirements and commitments pertaining to the area in the applicable implementation plan, and:

(1) For an area that violates the annual $PM_{2.5}$ NAAQS as of its attainment date, the annual average concentration for the most recent year at each monitor is 15.0 $\mu g/m^3$ or less (calculated according to the data analysis requirements in 40 CFR part 50, appendix N).

(2) For an area that violates the 24-hour $PM_{2.5}$ NAAQS as of its attainment date, the 98th percentile concentration for the most recent year at each monitor is 65 $\mu g/m^3$ or less (calculated according to the data analysis requirements in 40 CFR part 50, appendix N).

(b) An area that fails to attain the $PM_{2.5}$ NAAQS after receiving a 1-year attainment date extension may apply for a second 1-year attainment date extension pursuant to section 172(a)(2)(C)(ii) if the State has complied with all requirements and commitments pertaining to the area in the applicable implementation plan, and:

(1) For an area that violates the annual $PM_{2.5}$ NAAQS as of its attainment date, the two-year average of annual average concentrations at each monitor, based on the first extension year and the previous year, is 15.0 $\mu g/m^3$ or less (calculated according to the data analysis requirements in 40 CFR part 50, appendix N).

(2) For an area that violates the 24-hour $PM_{2.5}$ NAAQS as of its attainment date, the two-year average of annual 98th percentile concentrations at each monitor, based on the first extension year and the previous year, is 65 $\mu g/m^3$ or less (calculated according to the data analysis requirements in 40 CFR part 50, appendix N).

§ 51.1006 Redesignation to nonattainment following initial designations for the $PM_{2.5}$ NAAQS.

Any area that is initially designated ''attainment/unclassifiable'' for the $PM_{2.5}$ NAAQS may be subsequently redesignated to nonattainment if ambient air quality data in future years indicate that such a redesignation is appropriate. For any such area that is redesignated to nonattainment for the $PM_{2.5}$ NAAQS, any absolute, fixed date that is applicable in connection with the requirements of this part is extended by a period of time equal to the length of time between the effective date of the initial designation for the $PM_{2.5}$ NAAQS and the effective date of redesignation, except as otherwise provided in this subpart.

§ 51.1007 Attainment demonstration and modeling requirements.

(a) For any area designated as nonattainment for the $PM_{2.5}$ NAAQS, the State must submit an attainment demonstration showing that the area will attain the annual and 24-hour standards as expeditiously as practicable. The demonstration must meet the requirements of § 51.112 and Appendix W of this part and must include inventory data, modeling results, and emission reduction analyses on which the State has based its projected attainment date. The attainment date justified by the demonstration must be consistent with the requirements of § 51.1004(a). The modeled strategies must be consistent with requirements in § 51.1009 for RFP and in § 51.1010 for RACT and RACM. The attainment demonstration and supporting air quality modeling should be consistent with EPA's $PM_{2.5}$ modeling guidance.

(b) *Required time frame for obtaining emissions reductions.* For each nonattainment area, the State implementation plan must provide for implementation of all control measures needed for attainment as expeditiously as practicable, but no later than the beginning of the year prior to the attainment date. Consistent with section 172(c)(1) of the Act, the plan must provide for implementation of all RACM and RACT as expeditiously as practicable. The plan also must include RFP milestones in accordance with § 51.1009, and control measures needed to meet these milestones, as necessary.

§ 51.1008 Emission inventory requirements for the $PM_{2.5}$ NAAQS.

(a) For purposes of meeting the emission inventory requirements of section 172(c)(3) of the Act for nonattainment areas, the State shall, no later than three years after designation:

(1) Submit to EPA Statewide emission inventories for direct $PM_{2.5}$ emissions and emissions of $PM_{2.5}$ precursors. For purposes of defining the data elements for these inventories, the $PM_{2.5}$ and $PM_{2.5}$ precursor-relevant data element requirements under subpart A of this part shall apply.

(2) Submit any additional emission inventory information needed to support an attainment demonstration and RFP plan ensuring expeditious attainment of the annual and 24-hour $PM_{2.5}$ standards.

(b) For inventories required for submission under paragraph (a) of this section, a baseline emission inventory is required for the attainment demonstration required under § 51.1007 and for meeting RFP requirements

under § 51.1009. As determined on the date of designation, the base year for this inventory shall be the most recent calendar year for which a complete inventory was required to be submitted to EPA pursuant to subpart A of this part. The baseline emission inventory for calendar year 2002 or other suitable year shall be used for attainment planning and RFP plans for areas initially designated nonattainment for the $PM_{2.5}$ NAAQS in 2004–2005.

§ 51.1009 Reasonable further progress (RFP) requirements.

(a) Consistent with section 172(c)(2) of the Act, State implementation plans for areas designated nonattainment for the $PM_{2.5}$ NAAQS must demonstrate reasonable further progress as provided in § 51.1009(b) through (h).

(b) If the State submits to EPA an attainment demonstration and State implementation plan for an area which demonstrates that it will attain the PM NAAQS within five years of the date of designation, the State is not required to submit a separate RFP plan. Compliance with the emission reduction measures in the attainment demonstration and State implementation plan will meet the requirements for achieving reasonable further progress for the area.

(c) For any area for which the State submits to EPA an approvable attainment demonstration and State implementation plan that demonstrates the area needs an attainment date of more than five years from the date of designation, the State also must submit an RFP plan. The RFP plan must describe the control measures that provide for meeting the reasonable further progress milestones for the area, the timing of implementation of those measures, and the expected reductions in emissions of direct $PM_{2.5}$ and $PM_{2.5}$ attainment plan precursors. The RFP plan is due to EPA within three years of the date of designation.

(1) For any State that submits to EPA an approvable attainment demonstration and State implementation plan justifying an attainment date of more than five and less than nine years from the date of designation, the RFP plan must include 2009 emissions milestones for direct $PM_{2.5}$ and $PM_{2.5}$ attainment plan precursors demonstrating that reasonable further progress will be achieved for the 2009 emissions year.

(2) For any area that submits to EPA an approvable attainment demonstration and State implementation plan justifying an attainment date of nine or ten years from the date of designation, the RFP plan must include 2009 and 2012 emissions milestones for direct $PM_{2.5}$ and $PM_{2.5}$ attainment plan precursors demonstrating that reasonable further progress will be achieved for the 2009 and 2012 emissions years.

(d) The RFP plan must demonstrate that in each applicable milestone year, emissions will be at a level consistent with generally linear progress in reducing emissions between the base year and the attainment year.

(e) For a multi-State nonattainment area, the RFP plans for each State represented in the nonattainment area must demonstrate RFP on the basis of common multi-State inventories. The States within which the area is located must provide a coordinated RFP plan. Each State in a multi-State nonattainment area must ensure that the sources within its boundaries comply with enforceable emission levels and other requirements that in combination with the reductions planned in other state(s) will provide for attainment as expeditiously as practicable and demonstrate reasonable further progress.

(f) In the benchmark RFP plan, the State must identify direct $PM_{2.5}$ emissions and $PM_{2.5}$ attainment plan precursors regulated under the $PM_{2.5}$ attainment plan and specify target emission reduction levels to be achieved during the milestone years. In developing the benchmark RFP plan, the State must develop emission inventory information for the geographic area included in the plan and conduct the following calculations:

(1) For direct $PM_{2.5}$ emissions and each $PM_{2.5}$ attainment plan precursor addressed in the attainment strategy, the full implementation reduction is calculated by subtracting the full implementation inventory from the baseline year inventory.

(2) The ''milestone date fraction'' is the ratio of the number of years from the baseline year to the milestone inventory year divided by the number of years from the baseline year to the full implementation year.

(3) For direct $PM_{2.5}$ emissions and each $PM_{2.5}$ attainment plan precursor addressed in the attainment strategy, a benchmark emission reduction is calculated by multiplying the full implementation reduction by the milestone date fraction.

(4) The benchmark emission level in the milestone year is calculated for direct $PM_{2.5}$ emissions and each $PM_{2.5}$ attainment plan precursor by subtracting the benchmark emission reduction from the baseline year emission level. The benchmark RFP plan is defined as a plan that achieves benchmark emission levels for direct $PM_{2.5}$ emissions and each $PM_{2.5}$ attainment plan precursor addressed in the attainment strategy for the area.

(5) In comparing inventories between baseline and future years for direct $PM_{2.5}$ emissions and each $PM_{2.5}$ attainment plan precursor, the inventories must be derived from the same geographic area. The plan must include emissions estimates for all types of emitting sources and activities in the geographic area from which the emission inventories for direct $PM_{2.5}$ emissions and each $PM_{2.5}$ attainment plan precursor addressed in the plan are derived.

(6) For purposes of establishing motor vehicle emissions budgets for transportation conformity purposes (as required in 40 CFR part 93) for a $PM_{2.5}$ nonattainment area, the State shall include in its RFP submittal an inventory of on-road mobile source emissions in the nonattainment area.

(g) The RFP plan due three years after designation must demonstrate that emissions for the milestone year are either:

(1) At levels that are roughly equivalent to the benchmark emission levels for direct $PM_{2.5}$ emissions and each $PM_{2.5}$ attainment plan precursor to be addressed in the plan; or

(2) At levels included in an alternative scenario that is projected to result in a generally equivalent improvement in air quality by the milestone year as would be achieved under the benchmark RFP plan.

(h) The equivalence of an alternative scenario to the corresponding benchmark plan must be determined by comparing the expected air quality changes of the two scenarios at the design value monitor location. This comparison must use the information developed for the attainment plan to assess the relationship between emissions reductions of the direct $PM_{2.5}$ emissions and each $PM_{2.5}$ attainment plan precursor addressed in the attainment strategy and the ambient air quality improvement for the associated ambient species.

§ 51.1010 Requirements for reasonably available control technology (RACT) and reasonably available control measures (RACM).

(a) For each $PM_{2.5}$ nonattainment area, the State shall submit with the attainment demonstration a SIP revision demonstrating that it has adopted all reasonably available control measures (including RACT for stationary sources) necessary to demonstrate attainment as expeditiously as practicable and to meet any RFP requirements. The SIP revision shall contain the list of the potential measures considered by the State, and

information and analysis sufficient to support the State's judgment that it has adopted all RACM, including RACT.

(b) In determining whether a particular emission reduction measure or set of measures must be adopted as RACM under section 172(c)(1) of the Act, the State must consider the cumulative impact of implementing the available measures. Potential measures that are reasonably available considering technical and economic feasibility must be adopted as RACM if, considered collectively, they would advance the attainment date by one year or more.

§ 51.1011 Requirements for mid-course review.

(a) Any State that submits to EPA an approvable attainment plan for a $PM_{2.5}$ nonattainment area justifying an attainment date of nine or ten years from the date of designation also must submit to EPA a mid-course review six years from the date of designation.

(b) The mid-course review for an area must include:

(1) A review of emissions reductions and progress made in implementing control measures to reduce emissions of direct $PM_{2.5}$ and $PM_{2.5}$ attainment plan precursors contributing to $PM_{2.5}$ concentrations in the area;

(2) An analysis of changes in ambient air quality data for the area;

(3) Revised air quality modeling analysis to demonstrate attainment;

(4) Any new or revised control measures adopted by the State, as necessary to ensure attainment by the attainment date in the approved SIP of the nonattainment area.

§ 51.1012 Requirement for contingency measures.

Consistent with section 172(c)(9) of the Act, the State must submit in each attainment plan specific contingency measures to be undertaken if the area fails to make reasonable further progress, or fails to attain the $PM_{2.5}$ NAAQS by its attainment date. The contingency measures must take effect without significant further action by the State or EPA.

ENVIRONMENTAL PROTECTION AGENCY

40 CFR Part 52

[EPA–R04–OAR–2007–0835–200740(a); FRL–8475–4]

Approval of Implementation Plans of Kentucky: Clean Air Interstate Rule

AGENCY: Environmental Protection Agency (EPA).

ACTION: Direct final rule.

SUMMARY: EPA is approving a revision to the Kentucky State Implementation Plan (SIP) submitted on July 19, 2007. This revision addresses the requirements of EPA's Clean Air Interstate Rule (CAIR), promulgated on May 12, 2005 and subsequently revised on April 28, 2006, and December 13, 2006. EPA has determined that the SIP revision fully implements the CAIR requirements for Kentucky. Therefore, as a consequence of the SIP approval, EPA will also withdraw the CAIR Federal Implementation Plans (FIPs) concerning sulfur dioxide (SO_2), nitrogen oxides (NO_X) annual, and NO_X ozone season emissions for Kentucky. The CAIR FIPs for all States in the CAIR region were promulgated on April 28, 2006, and subsequently revised on December 13, 2006.

CAIR requires States to reduce emissions of SO_2 and NO_X that significantly contribute to, and interfere with maintenance of, the national ambient air quality standards for fine particulates and/or ozone in any downwind state. CAIR establishes State budgets for SO_2 and NO_X and requires States to submit SIP revisions that implement these budgets in States that EPA concluded did contribute to nonattainment in downwind states. States have the flexibility to choose which control measures to adopt to achieve the budgets, including participating in the EPA-administered cap-and-trade programs. In the SIP revision that EPA is approving, Kentucky would meet CAIR requirements by participating in the EPA-administered cap-and-trade programs addressing SO_2, NO_X annual, and NO_X ozone season emissions.

DATES: This direct final rule is effective December 3, 2007 without further notice, unless EPA receives adverse comment by November 5, 2007. If EPA receives such comments, it will publish a timely withdrawal of the direct final rule in the **Federal Register** and inform the public that the rule will not take effect.

ADDRESSES: Submit your comments, identified by Docket ID No. EPA–R04–OAR–2007–0835, by one of the following methods:

1. *http://www.regulations.gov*: Follow the on-line instructions for submitting comments.
2. *E-mail: Lesane.Heidi@epa.gov.*
3. *Fax:* (404) 562–9019.
4. *Mail:* ''EPA–R04–OAR–2007–0835'', Regulatory Development Section, Air Planning Branch, Air, Pesticides and Toxics Management Division, U.S. Environmental Protection Agency, Region 4, 61 Forsyth Street, SW., Atlanta, Georgia 30303–8960.
5. *Hand Delivery or Courier:* Heidi Lesane, Regulatory Development Section, Air Planning Branch, Air, Pesticides and Toxics Management Division, U.S. Environmental Protection Agency, Region 4, 61 Forsyth Street, SW., Atlanta, Georgia 30303–8960. Such deliveries are only accepted during the Regional Office's normal hours of operation. The Regional Office's official hours of business are Monday through Friday, 8:30 to 4:30, excluding Federal holidays.

Instructions: Direct your comments to Docket ID No. ''EPA–R04–OAR–2007–0835''. EPA's policy is that all comments received will be included in the public docket without change and may be made available online at *www.regulations.gov*, including any personal information provided, unless the comment includes information claimed to be Confidential Business Information (CBI) or other information whose disclosure is restricted by statute. Do not submit through *www.regulations.gov* or e-mail, information that you consider to be CBI or otherwise protected. The *www.regulations.gov* Web site is an ''anonymous access'' system, which means EPA will not know your identity or contact information unless you provide it in the body of your comment. If you send an e-mail comment directly to EPA without going through *www.regulations.gov,* your e-mail address will be automatically captured and included as part of the comment that is placed in the public docket and made available on the Internet. If you submit an electronic comment, EPA recommends that you include your name and other contact information in the body of your comment and with any disk or CD–ROM you submit. If EPA cannot read your comment due to technical difficulties and cannot contact you for clarification, EPA may not be able to consider your comment. Electronic files should avoid the use of special characters and any form of encryption and should be free of any defects or viruses. For additional information about EPA's public docket visit the EPA Docket Center homepage at *http://www.epa.gov/epahome/dockets.htm.*

Docket: All documents in the electronic docket are listed in the *www.regulations.gov* index. Although listed in the index, some information is not publicly available, i.e., CBI or other information whose disclosure is restricted by statute. Certain other material, such as copyrighted material, is not placed on the Internet and will be publicly available only in hard copy form. Publicly available docket materials are available either electronically in *www.regulations.gov* or in hard copy at the Regulatory Development Section, Air Planning Branch, Air, Pesticides and Toxics Management Division, U.S. Environmental Protection Agency, Region 4, 61 Forsyth Street, SW., Atlanta, Georgia 30303–8960. EPA requests that if at all possible, you contact the person listed in the **FOR FURTHER INFORMATION CONTACT** section to schedule your inspection. The Regional Office's official hours of business are Monday through Friday, 8:30 to 4:30, excluding Federal holidays.

FOR FURTHER INFORMATION CONTACT: If you have questions concerning today's action, please contact Heidi LeSane, Regulatory Development Section, Air Planning Branch, Air, Pesticides and Toxics Management Division, U.S. Environmental Protection Agency, Region 4, 61 Forsyth Street, SW., Atlanta, Georgia 30303–8960. The telephone number is (404) 562–9074. Mrs. LeSane can also be reached via electronic mail at *LeSane.Heidi@epa.gov.*

SUPPLEMENTARY INFORMATION:

Table of Contents

I. What Action Is EPA Taking?

EPA is approving a revision to Kentucky's SIP, submitted on July 19, 2007. In its SIP revision, Kentucky meets CAIR requirements by requiring certain electric generating units (EGUs) to participate in the EPA-administered State CAIR cap-and-trade programs addressing SO_2, NO_X annual, and NO_X ozone season emissions. EPA has determined that the SIP as revised meets the applicable requirements of CAIR. As a consequence of this SIP approval, EPA will also issue a final rule to withdraw the FIPs concerning SO_2, NO_X annual, and NO_X ozone season emissions for Kentucky. This action will delete and reserve 40 CFR 52.940 and 40 CFR 52.941. The withdrawal of the CAIR FIPs for Kentucky is a conforming amendment that must be made once the SIP is approved because EPA's authority to issue the FIPs was premised on a deficiency in the SIP for Kentucky. Once the SIP is fully approved, EPA no longer has authority for the FIPs. Thus, EPA will not have the option of maintaining the FIPs following the full SIP approval. Accordingly, EPA does not intend to offer an opportunity for a public hearing or an additional opportunity for written public comment on the withdrawal of the FIPs.

II. What Is the Regulatory History of the CAIR and the CAIR FIPs?

The CAIR was published by EPA on May 12, 2005 (70 FR 25162). In this rule, EPA determined that 28 States and the District of Columbia contribute significantly to nonattainment and interfere with maintenance of the national ambient air quality standards (NAAQS) for fine particulates ($PM_{2.5}$) and /or 8-hour ozone in downwind States in the eastern part of the country. As a result, EPA required those upwind States to revise their SIPs to include control measures that reduce emissions of SO_2, which is a precursor to $PM_{2.5}$ formation, and/or NO_X, which is a precursor to both ozone and $PM_{2.5}$ formation. For jurisdictions that contribute significantly to downwind $PM_{2.5}$ nonattainment, CAIR sets annual State-wide emission reduction requirements (i.e., budgets) for SO_2 and annual State-wide emission reduction requirements for NO_X. Similarly, for jurisdictions that contribute significantly to 8-hour ozone nonattainment, CAIR sets State-wide emission reduction requirements for NO_X for the ozone season (May 1st to September 30th). Under CAIR, States may implement these reduction requirements by participating in the EPA-administered cap-and-trade programs or by adopting any other control measures.

CAIR explains to subject States what must be included in SIPs to address the requirements of section 110(a)(2)(D) of the Clean Air Act (CAA) with regard to interstate transport with respect to the 8-hour ozone and $PM_{2.5}$ NAAQS. EPA made national findings, effective on May 25, 2005, that the States had failed to submit SIPs meeting the requirements of section 110(a)(2)(D). The SIPs were due in July 2000, 3 years after the promulgation of the 8-hour ozone and $PM_{2.5}$ NAAQS. These findings started a 2-year clock for EPA to promulgate a FIP to address the requirements of section 110(a)(2)(D). Under CAA section 110(c)(1), EPA may issue a FIP anytime after such findings are made and must do so within two years unless a SIP revision correcting the deficiency is approved by EPA before the FIP is promulgated.

On April 28, 2006, EPA promulgated FIPs for all States covered by CAIR in order to ensure the emissions reductions required by CAIR are achieved on schedule. Each CAIR State is subject to the FIPs until the State fully adopts, and EPA approves, a SIP revision meeting the requirements of CAIR. The CAIR FIPs require EGUs to participate in the EPA-administered CAIR SO_2, NO_X annual, and NO_X ozone season trading programs, as appropriate. The CAIR FIP SO_2, NO_X annual, and NO_X ozone season trading programs impose essentially the same requirements as, and are integrated with, the respective CAIR SIP trading programs. The integration of the FIP and SIP trading programs means that these trading programs will work together to create effectively a single trading program for each regulated pollutant (SO_2, NO_X annual, and NO_X ozone season) in all States covered by the CAIR FIP or SIP trading program for that pollutant. The CAIR FIPs also allow States to submit abbreviated SIP revisions that, if approved by EPA, will automatically replace or supplement certain CAIR FIP provisions (e.g., the methodology for allocating NO_X allowances to sources in the State), while the CAIR FIP remains in place for all other provisions.

On April 28, 2006, EPA published two additional CAIR-related final rules that added the States of Delaware and New Jersey to the list of States subject to CAIR for $PM_{2.5}$ and announced EPA's final decisions on reconsideration of five issues, without making any substantive changes to the CAIR requirements.

III. What Are the General Requirements of CAIR and the CAIR FIPs?

CAIR establishes State-wide emission budgets for SO_2 and NO_X and is to be implemented in two phases. The first phase of NO_X reductions starts in 2009 and continues through 2014, while the first phase of SO_2 reductions starts in 2010 and continues through 2014. The second phase of reductions for both NO_X and SO_2 starts in 2015 and continues thereafter. CAIR requires States to implement the budgets by either: (1) Requiring EGUs to participate in the EPA-administered cap-and-trade programs; or (2) adopting other control measures of the State's choosing and demonstrating that such control measures will result in compliance with the applicable State SO_2 and NO_X budgets.

The May 12, 2005 and April 28, 2006 CAIR rules provide model rules that States must adopt (with certain limited changes, if desired) if they want to participate in the EPA-administered trading programs.

With two exceptions, only States that choose to meet the requirements of CAIR through methods that exclusively regulate EGUs are allowed to participate in the EPA-administered trading programs. One exception is for States that adopt the opt-in provisions of the model rules to allow non-EGUs individually to opt into the EPA-administered trading programs. The other exception is for States that include all non-EGUs from their NO_X SIP Call trading programs in their CAIR NO_X ozone season trading programs.

IV. What Are the Types of CAIR SIP Submittals?

States have the flexibility to choose the type of control measures they will use to meet the requirements of CAIR. EPA anticipates that most States will choose to meet the CAIR requirements by selecting an option that requires EGUs to participate in the EPA-administered CAIR cap-and-trade programs. For such States, EPA has provided two approaches for submitting and obtaining approval for CAIR SIP revisions. States may submit full SIP revisions that adopt the model CAIR cap-and-trade rules. If approved, these SIP revisions will fully replace the CAIR FIPs. Alternatively, States may submit abbreviated SIP revisions. These SIP revisions will not replace the CAIR FIPs; however, the CAIR FIPs provide that, when approved, the provisions in these abbreviated SIP revisions will be used instead of or in conjunction with, as appropriate, the corresponding provisions of the CAIR FIPs (e.g., the

NO_X allowance allocation methodology).

A State submitting a full SIP revision may either adopt regulations that are substantively identical to the model rules or incorporate by reference the model rules. CAIR provides that States may only make limited changes to the model rules if the States want to participate in the EPA-administered trading programs. A full SIP revision may change the model rules only by altering their applicability and allowance allocation provisions to:

1. Include NO_X SIP Call trading sources that are not EGUs under CAIR in the CAIR NO_X ozone season trading program;

2. Provide for allocation of NO_X annual or ozone season allowances by the State, rather than the Administrator of the EPA or the Administrator's duly authorized representative (Administrator), and using a methodology chosen by the State;

3. Provide for State allocation of NO_X annual allowances from the compliance supplement pool (CSP) using the State's choice of allowed, alternative methodologies; or

4. Allow units that are not otherwise CAIR units to opt individually into the CAIR SO_2, NO_X annual, or NO_X ozone season trading programs under the opt-in provisions in the model rules.

An approved CAIR full SIP revision addressing EGUs' SO_2, NO_X annual, or NO_X ozone season emissions will replace the CAIR FIP for that State for the respective EGU emissions.

V. Analysis of Kentucky's CAIR SIP Submittal

A. State Budgets for Allowance Allocations

The CAIR NO_X annual and ozone season budgets were developed from historical heat input data for EGUs. Using these data, EPA calculated annual and ozone season regional heat input values, which were multiplied by 0.15 pounds per million British thermal units (lb/mmBtu), for phase 1, and 0.125 lb/mmBtu, for phase 2, to obtain regional NO_X budgets for 2009–2014 and for 2015 and thereafter, respectively. EPA derived the State NO_X annual and ozone season budgets from the regional budgets using State heat input data adjusted by fuel factors.

The CAIR State SO_2 budgets were derived by discounting the tonnage of emissions authorized by annual allowance allocations under the Acid Rain Program under title IV of the CAA. Under CAIR, each allowance allocated in the Acid Rain Program for the years in phase 1 of CAIR (2010 through 2014) authorizes 0.50 ton of SO_2 emissions in the CAIR trading program, and each Acid Rain Program allowance allocated for the years in phase 2 of CAIR (2015 and thereafter) authorizes 0.35 ton of SO_2 emissions in the CAIR trading program.

In this action, EPA is approving Kentucky's SIP revision that adopts the budgets established for the Commonwealth in CAIR, i.e., 83,205 (2009–2014) and 69,337 (2015–thereafter) tons for NO_X annual emissions, 36,109 (2009–2014) and 30,651 (2015–thereafter) tons for NO_X ozone season emissions, and 188,773 (2010–2014) and 132,141 (2015–thereafter) tons for SO_2 emissions. Kentucky's SIP revision sets these budgets as the total amounts of allowances available for allocation for each year under the EPA-administered cap-and-trade programs.

B. CAIR Cap-and-Trade Programs

The CAIR NO_X annual and ozone-season model trading rules both largely mirror the structure of the NO_X SIP Call model trading rule in 40 CFR part 96, subparts A through I. While the provisions of the NO_X annual and ozone-season model rules are similar, there are some differences. For example, the NO_X annual model rule (but not the NO_X ozone season model rule) provides for a CSP, which is discussed below and under which allowances may be awarded for early reductions of NO_X annual emissions. As a further example, the NO_X ozone season model rule reflects the fact that the CAIR NO_X ozone season trading program replaces the NO_X SIP Call trading program after the 2008 ozone season and is coordinated with the NO_X SIP Call program. The NO_X ozone season model rule provides incentives for early emissions reductions by allowing banked, pre-2009 NO_X SIP Call allowances to be used for compliance in the CAIR NO_X ozone-season trading program. In addition, States have the option of continuing to meet their NO_X SIP Call requirement by participating in the CAIR NO_X ozone season trading program and including all their NO_X SIP Call trading sources in that program.

The provisions of the CAIR SO_2 model rule are also similar to the provisions of the NO_X annual and ozone season model rules. However, the SO_2 model rule is coordinated with the ongoing Acid Rain SO_2 cap-and-trade program under CAA title IV. The SO_2 model rule uses the title IV allowances for compliance, with each allowance allocated for 2010–2014 authorizing only 0.50 ton of emissions and each allowance allocated for 2015 and thereafter authorizing only 0.35 ton of emissions. Banked title IV allowances allocated for years before 2010 can be used at any time in the CAIR SO_2 cap-and-trade program, with each such allowance authorizing 1 ton of emissions. Title IV allowances are to be freely transferable among sources covered by the Acid Rain Program and sources covered by the CAIR SO_2 cap-and-trade program.

EPA also used the CAIR model trading rules as the basis for the trading programs in the CAIR FIPs. The CAIR FIP trading rules are virtually identical to the CAIR model trading rules, with changes made to account for federal rather than state implementation. The CAIR model SO_2, NO_X annual, and NO_X ozone season trading rules and the respective CAIR FIP trading rules are designed to work together as integrated SO_2, NO_X annual, and NO_X ozone season trading programs.

In the SIP revision, Kentucky chooses to implement its CAIR budgets by requiring EGUs to participate in EPA-administered cap-and-trade programs for SO_2, NO_X annual, and NO_X ozone season emissions. Kentucky has adopted a full SIP revision that adopts, with certain allowed changes discussed below, the CAIR model cap-and-trade rules for SO_2, NO_X annual, and NO_X ozone season emissions.

C. Applicability Provisions for Non-EGU NO_X SIP Call Sources

In general, the CAIR model trading rules apply to any stationary, fossil-fuel-fired boiler or stationary, fossil-fuel-fired combustion turbine serving at any time, since the later of November 15, 1990 or the start-up of the unit's combustion chamber, a generator with nameplate capacity of more than 25 megawatt electrical (MWe) producing electricity for sale.

States have the option of bringing in, for the CAIR NO_X ozone season program only, those units in the State's NO_X SIP Call trading program that are not EGUs as defined under CAIR. EPA advises States exercising this option to add the applicability provisions in the State's NO_X SIP Call trading rule for non-EGUs to the applicability provisions in 40 CFR 96.304 in order to include in the CAIR NO_X ozone season trading program all units required to be in the State's NO_X SIP Call trading program that are not already included under 40 CFR 96.304. Under this option, the CAIR NO_X ozone season program must cover all large industrial boilers and combustion turbines, as well as any small EGUs (i.e. units serving a generator with a nameplate capacity of 25 MWe or less)

that the State currently requires to be in the NO_X SIP Call trading program.

Kentucky has chosen to expand the applicability provisions of the CAIR NO_X ozone season trading program to include all non-EGUs in the State's NO_X SIP Call trading program. Kentucky has committed to revising the applicability section in its CAIR NO_X ozone season rule in order to clarify that, as intended by the State, units subject to its NO_X SIP Call program and brought into its CAIR program through the allowed expansion of the CAIR NO_X ozone season applicability provisions are to be treated as CAIR NO_X ozone season units and certain definitions from 401 KAR 51:001 apply to the provisions that bring these units into the CAIR program. EPA determined after review of Kentucky's final rules, and after Kentucky had adopted other necessary revisions to its CAIR rules, that these provisions needed clarification. However, while the clarifications are needed, EPA interprets Kentucky's current rule to provide that the NO_X SIP Call units are subject to the requirements for CAIR NO_X ozone season units and that the NO_X SIP Call definitions are used in applying the applicability provisions that bring in NO_X SIP Call units. In addition, Kentucky has committed to correct two citation references in its CAIR NO_X ozone season allowance allocation methodology needed in order to reference correctly its applicability section. EPA interprets Kentucky's current rule as applying the correct references.

Kentucky has also committed to revising the definitions of ''commence commercial operation'' and ''commence operation'' in its CAIR NO_X ozone season rule in order to clarify the deadlines, for meeting monitoring and reporting requirements, that apply to the NO_X SIP Call units that are brought into the CAIR program but do not serve generators producing electricity for sale, as intended by the State. EPA determined after review of Kentucky's final rules, and after Kentucky had adopted other necessary revisions to its CAIR rules, that these provisions needed clarification.

EPA has outlined these necessary revisions in a technical support document. EPA received a letter from Kentucky dated September 11, 2007, that provides a commitment to make these rule revisions in its CAIR rules in 2008. Specifically, in the September 11, 2007, letter, Kentucky commits to make the revisions discussed above to its CAIR NO_X Ozone Season trading rule, 401 KAR 51:220.

D. NO_X Allowance Allocations

Under the NO_X allowance allocation methodology in the CAIR model trading rules and in the CAIR FIP, NO_X annual and ozone season allowances are allocated to units that have operated for five years, based on heat input data from a three-year period that are adjusted for fuel type by using fuel factors of 1.0 for coal, 0.6 for oil, and 0.4 for other fuels. The CAIR model trading rules and the CAIR FIP also provide a new unit set-aside from which units without five years of operation are allocated allowances based on the units' prior year emissions.

States may establish in their SIP submissions a different NO_X allowance allocation methodology that will be used to allocate allowances to sources in the States if certain requirements are met concerning the timing of submission of units' allocations to the Administrator for recordation and the total amount of allowances allocated for each control period. In adopting alternative NO_X allowance allocation methodologies, States have flexibility with regard to:

1. The cost to recipients of the allowances, which may be distributed for free or auctioned;

2. The frequency of allocations;

3. The basis for allocating allowances, which may be distributed, for example, based on historical heat input or electric and thermal output; and

4. The use of allowance set-asides and, if used, their size.

Kentucky has chosen to replace the provisions of the CAIR NO_X annual and CAIR NO_X ozone season model trading rules concerning the allocation of NO_X annual and ozone season allowances with its own methodology. Kentucky has chosen to distribute 98% of its NO_X annual allowances based upon adjusted heat input. In Kentucky's final CAIR SIP submittal, Kentucky already made initial allocations for the control periods spanning from 2009 to 2014. In 2009, Kentucky will submit one-year allocations for the 2015 control period, and for every control period thereafter Kentucky will continue to submit allocations six years in advance. For example, in 2010, one-year allocations will be made for the 2016 control period; in 2011, one-year allocations will be made for the 2017 control period, etc. The remaining 2% of Kentucky's allowances will be held and sold as needed by the Commonwealth of Kentucky, with the proceeds to be deposited into Kentucky's general fund.

E. Allocation of NO_X Allowances From the Compliance Supplement Pool

The CAIR establishes a compliance supplement pool (CSP) to provide an incentive for early reductions in NO_X annual emissions. The CSP consists of 200,000 CAIR NO_X annual allowances of vintage 2009 for the entire CAIR region, and a State's share of the CSP is based upon the projected magnitude of the emission reductions required by CAIR in that State. States may distribute CSP allowances, one allowance for each ton of early reduction, to sources that make NO_X reductions during 2007 or 2008 beyond what is required by any applicable State or Federal emission limitation. States also may distribute CSP allowances based upon a demonstration of need for an extension of the 2009 deadline for implementing emission controls.

The CAIR annual NO_X model trading rule establishes specific methodologies for allocations of CSP allowances. States may choose an allowed, alternative CSP allocation methodology to be used to allocate CSP allowances to sources in the States.

Kentucky has chosen to modify the provisions of the CAIR NO_x annual model trading rule concerning the allocation of allowances from the CSP. Kentucky has chosen to distribute CSP allowances using an allocation methodology that continues to reward early reductions, but hinges on heat input data. Initially, the portion of the CSP that is available to a given source is determined by the following formula:

$$ERC_U = \frac{(BHI_U)}{BHI_T}(CSP_T)$$

Where: ERC_U is the Early Reduction Credit available to the unit, BHI_U is the Baseline Heat Input of the unit, BHI_T is the Baseline Heat Input from all sources within Kentucky, and CSP_T is 14,935 tons, the Early Reduction Credits available pursuant to 40 CFR 96.143(a).

Kentucky also makes available portions of the CSP for units that are able to demonstrate need, in a manner that is identical to 40 CFR 96.143(c). Remaining credits are then distributed on a pro rata basis, up to the total early reduction credits requested pursuant to 40 CFR 96.143(b), to those CAIR NO_X units with early reduction credits that exceeded the amount of credits made available by the previous calculation.

F. Individual Opt-In Units

The opt-in provisions of the CAIR SIP model trading rules allow certain non-EGUs (i.e., boilers, combustion turbines, and other stationary fossil-fuel-fired devices) that do not meet the

applicability criteria for a CAIR trading program to participate voluntarily in (i.e., opt into) the CAIR trading program. A non-EGU may opt into one or more of the CAIR trading programs. In order to qualify to opt into a CAIR trading program, a unit must vent all emissions through a stack and be able to meet monitoring, recordkeeping, and recording requirements of 40 CFR part 75. The owners and operators seeking to opt a unit into a CAIR trading program must apply for a CAIR opt-in permit. If the unit is issued a CAIR opt-in permit, the unit becomes a CAIR unit, is allocated allowances, and must meet the same allowance-holding and emissions monitoring and reporting requirements as other units subject to the CAIR trading program. The opt-in provisions provide for two methodologies for allocating allowances for opt-in units, one methodology that applies to opt-in units in general and a second methodology that allocates allowances only to opt-in units that the owners and operators intend to repower before January 1, 2015.

States have several options concerning the opt-in provisions. States may adopt the CAIR opt-in provisions entirely or may adopt them but exclude one of the methodologies for allocating allowances. States may also decline to adopt the opt-in provisions at all.

Kentucky has chosen to allow non-EGUs meeting certain requirements to opt into the CAIR NO_X annual trading program, including both of the opt-in allocation methods in the model rule.

Kentucky has chosen to allow non-EGUs meeting certain requirements to opt into the CAIR NO_X ozone season trading program, including both of the opt-in allocation methods in the model rule.

Kentucky has chosen to allow certain non-EGUs to opt into the CAIR SO_2 trading program, including both of the opt-in allocation methods in the model rule.

VI. Final Action

EPA is approving Kentucky's full CAIR SIP revision submitted on July 19, 2007. Under this SIP revision, Kentucky is choosing to participate in the EPA-administered cap-and-trade programs for SO_2, NO_X annual, and NO_X ozone season emissions. The SIP revision (interpreted and clarified as discussed above) meets the applicable requirements in 40 CFR 51.123(o) and (aa), with regard to NO_X annual and NO_X ozone season emissions, and 40 CFR 51.124(o), with regard to SO_2 emissions. Further, Kentucky has agreed to make the technical corrections to certain provisions as discussed above. Therefore, EPA has determined that the SIP as revised will meet the requirements of CAIR. As a consequence of the SIP approval, the Administrator of EPA will also issue, without providing an opportunity for a public hearing or an additional opportunity for written public comment, a final rule to withdraw the CAIR FIPs concerning SO_2, NO_X annual, and NO_X ozone season emissions for Kentucky. This action will delete and reserve 40 CFR 52.940 and 40 CFR 52.941.

EPA is approving the aforementioned changes to the SIP. EPA is publishing this rule without prior proposal because the Agency views this as a noncontroversial submittal and anticipates no adverse comments. However, in the proposed rules section of this **Federal Register** publication, EPA is publishing a separate document that will serve as the proposal to approve the SIP revision should adverse comments be filed. This rule will be effective December 3, 2007 without further notice unless the Agency receives adverse comments by November 5, 2007.

If the EPA receives such comments, then EPA will publish a document withdrawing the final rule and informing the public that the rule will not take effect. All public comments received will then be addressed in a subsequent final rule based on the proposed rule. EPA will not institute a second comment period. Parties interested in commenting should do so at this time. If no such comments are received, the public is advised that this rule will be effective on December 3, 2007 and no further action will be taken on the proposed rule.

VII. Statutory and Executive Order Reviews

Under Executive Order 12866 (58 FR 51735, October 4, 1993), this action is not a ''significant regulatory action'' and therefore is not subject to review by the Office of Management and Budget. For this reason, this action is also not subject to Executive Order 13211, ''Actions Concerning Regulations That Significantly Affect Energy Supply, Distribution, or Use'' (66 FR 28355, May 22, 2001). This action merely approves state law as meeting Federal requirements and imposes no additional requirements beyond those imposed by state law. Accordingly, the Administrator certifies that this rule will not have a significant economic impact on a substantial number of small entities under the Regulatory Flexibility Act (5 U.S.C. 601 *et seq.*). Because this rule approves pre-existing requirements under state law and does not impose any additional enforceable duty beyond that required by state law, it does not contain any unfunded mandate or significantly or uniquely affect small governments, as described in the Unfunded Mandates Reform Act of 1995 (Pub. L. 104–4).

This rule also does not have tribal implications because it will not have a substantial direct effect on one or more Indian tribes, on the relationship between the Federal Government and Indian tribes, or on the distribution of power and responsibilities between the Federal Government and Indian tribes, as specified by Executive Order 13175 (65 FR 67249, November 9, 2000). This action also does not have Federalism implications because it does not have substantial direct effects on the States, on the relationship between the national government and the States, or on the distribution of power and responsibilities among the various levels of government, as specified in Executive Order 13132 (64 FR 43255, August 10, 1999). This action merely approves a state rule implementing a Federal standard, and does not alter the relationship or the distribution of power and responsibilities established in the CAA. This rule also is not subject to Executive Order 13045 ''Protection of Children from Environmental Health Risks and Safety Risks'' (62 FR 19885, April 23, 1997), because it is not economically significant.

In reviewing SIP submissions, EPA's role is to approve state choices, provided that they meet the criteria of the CAA. In this context, in the absence of a prior existing requirement for the State to use voluntary consensus standards (VCS), EPA has no authority to disapprove a SIP submission for failure to use VCS. It would thus be inconsistent with applicable law for EPA, when it reviews a SIP submission, to use VCS in place of a SIP submission that otherwise satisfies the provisions of the CAA. Thus, the requirements of section 12(d) of the National Technology Transfer and Advancement Act of 1995 (15 U.S.C. 272 note) do not apply. This rule does not impose an information collection burden under the provisions of the Paperwork Reduction Act of 1995 (44 U.S.C. 3501 *et seq.*).

The Congressional Review Act, 5 U.S.C. 801 *et seq.*, as added by the Small Business Regulatory Enforcement Fairness Act of 1996, generally provides that before a rule may take effect, the agency promulgating the rule must submit a rule report, which includes a copy of the rule, to each House of the Congress and to the Comptroller General of the United States. EPA will submit a report containing this rule and other

required information to the U.S. Senate, the U.S. House of Representatives, and the Comptroller General of the United States prior to publication of the rule in the **Federal Register**. A major rule cannot take effect until 60 days after it is published in the **Federal Register**. This action is not a ''major rule'' as defined by 5 U.S.C. 804(2).

Under section 307(b)(1) of the CAA, petitions for judicial review of this action must be filed in the United States Court of Appeals for the appropriate circuit by December 3, 2007. Filing a petition for reconsideration by the Administrator of this final rule does not affect the finality of this rule for the purposes of judicial review nor does it extend the time within which a petition for judicial review may be filed, and shall not postpone the effectiveness of such rule or action. This action may not be challenged later in proceedings to enforce its requirements. (See section 307(b)(2).)

List of Subjects 40 CFR Part 52

Environmental protection, Air pollution control, Electric utilities, Intergovernmental relations, Nitrogen oxides, Ozone, Particulate matter, Reporting and recordkeeping requirements, Sulfur dioxide.

Dated: September 21, 2007.

J.I. Palmer, Jr.,

Regional Administrator, Region 4.

■ 40 CFR part 52 is amended as follows:

Protection of Stratospheric Ozone: Notice 22 for Significant New Alternatives Policy Program

AGENCY: Environmental Protection Agency (EPA).

ACTION: Determination of acceptability.

SUMMARY: This Determination of Acceptability expands the list of acceptable substitutes for ozone-depleting substances under the U.S. Environmental Protection Agency's (EPA) Significant New Alternatives Policy (SNAP) program. The determinations concern new substitutes for use in the refrigeration and air conditioning sector.

DATES: This action is effective on October 4, 2007.

ADDRESSES: EPA has established a docket for this action under Docket ID No. EPA–HQ–OAR–2003–0118 (continuation of Air Docket A–91–42). All electronic documents in the docket are listed in the index at *http://www.regulations.gov.* Although listed in the index, some information is not publicly available, i.e., Confidential Business Information (CBI) or other information whose disclosure is restricted by statute. Publicly available docket materials are available either electronically at *www.regulations.gov* or in hard copy at the EPA Air Docket (No. A–91–42), EPA/DC, EPA West, Room 3334, 1301 Constitution Avenue, NW., Washington, DC. The Public Reading Room is open from 8:30 a.m. to 4:30 p.m., Monday through Friday, excluding legal holidays. The telephone number for the Public Reading Room is (202) 566–1744, and the telephone number for the Air Docket is (202) 566–1742.

FOR FURTHER INFORMATION CONTACT: Margaret Sheppard by telephone at (202) 343–9163, by facsimile at (202) 343–2362, by e-mail at *sheppard.margaret@epa.gov,* or by mail at U.S. Environmental Protection Agency, Mail Code 6205J, 1200 Pennsylvania Avenue, NW., Washington, DC 20460. Overnight or courier deliveries should be sent to the office location at 1310 L Street, NW., 10th floor, Washington, DC 20005.

For more information on the Agency's process for administering the SNAP program or criteria for evaluation of substitutes, refer to the original SNAP rulemaking published in the **Federal Register** on March 18, 1994 (59 FR 13044). Notices and rulemakings under the SNAP program, as well as other EPA publications on protection of stratospheric ozone, are available at EPA's Ozone Depletion World Wide Web site at *http://www.epa.gov/ozone/* including the SNAP portion at *http://www.epa.gov/ozone/snap/*.

Approval and Promulgation of Implementation Plans and Designation of Areas for Air Quality Planning Purposes; Ohio; Indiana; Redesignation of the Ohio and Indiana Portions of the Cincinnati-Hamilton Area to Attainment for Ozone

AGENCY: Environmental Protection Agency (EPA).

ACTION: Final rule.

SUMMARY: EPA is approving the requests of Ohio and Indiana to redesignate the Ohio and Indiana portions of the Cincinnati-Hamilton, OH–KY–IN 8-hour ozone nonattainment area, "the Cincinnati-Hamilton area," to attainment for that standard, because these requests meet the statutory requirements for redesignation under the Clean Air Act (CAA). The Ohio Environmental Protection Agency (Ohio EPA) and the Indiana Department of Environmental Management (IDEM) submitted these requests on December 14, 2009, and January 21, 2010, respectively. (EPA will address the Kentucky portion of the Cincinnati-Hamilton area in a separate rulemaking action.)

These approvals involve several related actions. EPA is making a determination under the CAA that the Cincinnati-Hamilton area has attained the 1997 8-hour ozone National Ambient Air Quality Standard (NAAQS). The Cincinnati-Hamilton area includes Butler, Clermont, Clinton, Hamilton, and Warren Counties in Ohio, Lawrenceburg Township in Dearborn County, Indiana, and Boone, Campbell, and Kenton Counties in Kentucky. This determination is based on three years of complete, quality-assured ambient air quality monitoring data for the 2007–2009 ozone seasons that demonstrate that the 8-hour ozone NAAQS has been attained in the entire Cincinnati-Hamilton area. EPA is also approving, as revisions to the Ohio and Indiana State Implementation Plans (SIPs), the States' plans for maintaining the 8-hour ozone NAAQS through 2020 in the area.

EPA is approving the 2002 base year emissions inventory submitted by IDEM on June 13, 2007, as meeting the base year emissions inventory requirement of the CAA for the Indiana portion of the Cincinnati-Hamilton area. EPA is approving the 2005 base year emissions inventory submitted by Ohio EPA as part of its redesignation request as meeting the base year emissions inventory requirements of the CAA for the Ohio portion of the Cincinnati-Hamilton area. Finally, EPA finds adequate and is approving the States' 2015 and 2020 Motor Vehicle Emission Budgets (MVEBs) for the Ohio and Indiana portion of the Cincinnati-Hamilton area.

DATES: This final rule is effective May 11, 2010.

ADDRESSES: EPA has established dockets for this action: Docket ID No. EPA–R05–OAR–2009–0928 and ID No. EPA–R05–OAR–2010–0046. All documents in the docket are listed on the *www.regulations.gov* Web site. Although listed in the index, some information is not publicly available, *i.e.,* Confidential Business Information (CBI) or other information whose disclosure is restricted by statute. Certain other material, such as copyrighted material, is not placed on the Internet and will be publicly available only in hard copy form. Publicly available docket materials are available either electronically in *www.regulations.gov* or in hard copy at the Environmental Protection Agency, Region 5, Air and Radiation Division, 77 West Jackson Boulevard, Chicago, Illinois 60604. This facility is open from 8:30 a.m. to 4:30 p.m., Monday through Friday, excluding Federal holidays. We recommend that you telephone Kathleen D'Agostino, Environmental Engineer, at (312) 886–1767 before visiting the Region 5 office.

FOR FURTHER INFORMATION CONTACT: Kathleen D'Agostino, Environmental Engineer, Criteria Pollutant Section, Air Programs Branch (AR–18J), U.S. Environmental Protection Agency, Region 5, 77 West Jackson Boulevard, Chicago, Illinois 60604, (312) 886–1767, *dagostino.kathleen@epa.gov.*

SUPPLEMENTARY INFORMATION: Throughout this document whenever "we," "us," or "our" is used, we mean EPA. This supplementary information section is arranged as follows:

Table of Contents

I. What is the background for these actions?

The background for today's actions is discussed in detail in EPA's February 26, 2010, proposal (75 FR 8871). In that rulemaking, we noted that, under EPA regulations at 40 CFR part 50, the 8-hour ozone standard is attained when the three-year average of the annual fourth-highest daily maximum 8-hour average ozone concentrations is less than or equal to 0.08 ppm. (*See* 69 FR 23857 (April 30, 2004) for further information.) Under the CAA, EPA may redesignate nonattainment areas to attainment if sufficient complete, quality-assured data are available to determine that the area has attained the standard and if it meets the other CAA redesignation requirements in section 107(d)(3)(E).

The Ohio EPA and IDEM submitted requests to redesignate the Ohio and Indiana portions of the Cincinnati-Hamilton area to attainment for the 8-hour ozone standard on December 14, 2009, and January 21, 2010, respectively. The redesignation requests included three years of complete, quality-assured data for the period of 2007 through 2009, indicating the 8-hour NAAQS for ozone, as promulgated in 1997, had been attained for the Cincinnati-Hamilton area. The February 26, 2010, proposed rule provides a detailed discussion of how Ohio and Indiana met this and other CAA requirements.

II. What comments did we receive on the proposed rule?

EPA provided a 30-day review and comment period. The comment period closed on March 29, 2010. We received no comments on the proposed rule.

III. What action is EPA taking?

EPA is making a determination that the Cincinnati-Hamilton area has attained the 1997 8-hour ozone NAAQS. EPA is also approving the maintenance plan SIP revisions for the Ohio and Indiana portions of the Cincinnati-Hamilton area. EPA's approval of the maintenance plans is based on the States' demonstrations that the plans meet the requirements of section 175A of the CAA. After evaluating the redesignation requests submitted by Ohio and Indiana, EPA believes that the requests meet the redesignation criteria set forth in section 107(d)(3)(E) of the CAA. Therefore, EPA is approving the redesignation of the Ohio and Indiana portions of the Cincinnati-Hamilton area from nonattainment to attainment for the 1997 8-hour ozone NAAQS. EPA is also approving Ohio EPA's 2005 base year emissions inventory for the Ohio

portion of the Cincinnati-Hamilton area and IDEM's 2002 base year emissions inventory for Dearborn County as meeting the requirements of section 172(c)(3) of the CAA. Finally, EPA finds adequate and is approving the States' 2015 and 2020 MVEBs for Ohio and Indiana portions of the Cincinnati-Hamilton area.

In accordance with 5 U.S.C. 553(d), EPA finds there is good cause for this action to become effective immediately upon publication. This is because a delayed effective date is unnecessary due to the nature of a redesignation to attainment, which relieves the area from certain CAA requirements that would otherwise apply to it. The immediate effective date for this action is authorized under both 5 U.S.C. 553(d)(1), which provides that rulemaking actions may become effective less than 30 days after publication if the rule "grants or recognizes an exemption or relieves a restriction," and section 553(d)(3), which allows an effective date less than 30 days after publication "as otherwise provided by the agency for good cause found and published with the rule." The purpose of the 30-day waiting period prescribed in section 553(d) is to give affected parties a reasonable time to adjust their behavior and prepare before the final rule takes effect. Today's rule, however, does not create any new regulatory requirements such that affected parties would need time to prepare before the rule takes effect. Rather, today's rule relieves the state of various requirements for this 8-hour ozone nonattainment area. For these reasons, EPA finds good cause under 5 U.S.C. 553(d)(3) for this action to become effective on the date of publication of this action.

IV. Statutory and Executive Order Reviews

Under the CAA, redesignation of an area to attainment and the accompanying approval of a maintenance plan under section 107(d)(3)(E) are actions that affect the status of a geographical area and do not impose any additional regulatory requirements on sources beyond those imposed by state law. A redesignation to attainment does not in and of itself create any new requirements, but rather results in the applicability of requirements contained in the CAA for areas that have been redesignated to attainment. Moreover, the Administrator is required to approve a SIP submission that complies with the provisions of the CAA and applicable Federal regulations. 42 U.S.C. 7410(k); 40 CFR 52.02(a). Thus, in reviewing SIP submissions, EPA's role is to approve state choices, provided that they meet the criteria of the CAA. These actions do not impose additional requirements beyond those imposed by state law and the CAA. For that reason, these actions:

- Are not "significant regulatory actions" subject to review by the Office of Management and Budget under Executive Order 12866 (58 FR 51735, October 4, 1993);
- Do not impose an information collection burden under the provisions of the Paperwork Reduction Act (44 U.S.C. 3501 *et seq.*);
- Are certified as not having a significant economic impact on a substantial number of small entities under the Regulatory Flexibility Act (5 U.S.C. 601 *et seq.*);
- Do not contain any unfunded mandate or significantly or uniquely affect small governments, as described in the Unfunded Mandates Reform Act of 1995 (Pub. L. 104–4);
- Do not have Federalism implications as specified in Executive Order 13132 (64 FR 43255, August 10, 1999);
- Are not an economically significant regulatory action based on health or safety risks subject to Executive Order 13045 (62 FR 19885, April 23, 1997);
- Are not a significant regulatory action subject to Executive Order 13211 (66 FR 28355, May 22, 2001);
- Are not subject to requirements of section 12(d) of the National Technology Transfer and Advancement Act of 1995 (15 U.S.C. 272 note) because application of those requirements would be inconsistent with the CAA; and
- Do not provide EPA with the discretionary authority to address, as appropriate, disproportionate human health or environmental effects, using practicable and legally permissible methods, under Executive Order 12898 (59 FR 7629, February 16, 1994).

In addition, this rule does not have tribal implications as specified by Executive Order 13175 (65 FR 67249, November 9, 2000), because the SIP is not approved to apply in Indian country located in the state, and EPA notes that it will not impose substantial direct costs on tribal governments or preempt tribal law.

The Congressional Review Act, 5 U.S.C. 801 *et seq.,* as added by the Small Business Regulatory Enforcement Fairness Act of 1996, generally provides that before a rule may take effect, the agency promulgating the rule must submit a rule report, which includes a copy of the rule, to each House of the Congress and to the Comptroller General of the United States. EPA will submit a report containing this action and other required information to the U.S. Senate, the U.S. House of Representatives, and the Comptroller General of the United States prior to publication of the rule in the **Federal Register.** A major rule cannot take effect until 60 days after it is published in the **Federal Register.** This action is not a "major rule" as defined by 5 U.S.C. 804(2).

Under section 307(b)(1) of the CAA, petitions for judicial review of this action must be filed in the United States Court of Appeals for the appropriate circuit by July 12, 2010. Filing a petition for reconsideration by the Administrator of this final rule does not affect the finality of this action for the purposes of judicial review nor does it extend the time within which a petition for judicial review may be filed, and shall not postpone the effectiveness of such rule or action. This action may not be challenged later in proceedings to enforce its requirements. (*See* section 307(b)(2).)

List of Subjects

40 CFR Part 52

Environmental protection, Air pollution control, Intergovernmental relations, Nitrogen oxides, Ozone, Volatile organic compounds.

40 CFR Part 81

Environmental protection, Air pollution control, National parks, Wilderness areas.

Dated: April 22, 2010.

Bharat Mathur,

Acting Regional Administrator, Region 5.

■ Parts 52 and 81, chapter I, title 40 of the Code of Federal Regulations is amended as follows:

PART 52—[AMENDED]

■ 1. The authority citation for part 52 continues to read as follows:

Authority: 42 U.S.C. 7401 *et seq.*

Subpart P—Indiana

■ 2. Section 52.777 is amended by adding paragraphs (nn) and (oo) to read as follows:

§ 52.777 Control strategy: Photochemical oxidants (hydrocarbons).

* * * * *

(nn) Approval—Indiana's 2002 inventory satisfies the base year emissions inventory requirements of section 172(c)(3) of the Clean Air Act for the Indiana portion of the Cincinnati-Hamilton, OH–KY–IN area under the 1997 8-hour ozone standard.

(oo) Approval—On January 21, 2010, the Indiana Department of

Environmental Management submitted a request to redesignate the Indiana portion of the Cincinnati-Hamilton, OH–KY–IN area to attainment of the 8-hour ozone NAAQS. As part of the redesignation request, the State submitted a maintenance plan as required by section 175A of the Clean Air Act. Elements of the section 175 maintenance plan include a contingency plan and an obligation to submit a subsequent maintenance plan revision in 8 years as required by the Clean Air Act. The 2015 motor vehicle emissions budgets for the Ohio and Indiana portions of the Cincinnati-Hamilton, OH–KY–IN area are 31.73 tpd for VOC and 49.00 tpd for NO_X. The 2020 motor vehicle emissions budgets for the Ohio and Indiana portions of the area are 28.82 tpd for VOC and 34.39 tpd for NO_X.

* * * * *

Subpart KK—Ohio

■ 3. Section 52.1885 is amended by adding paragraphs (ff)(10) and (hh)(3) to read as follows:

§ 52.1885 Control strategy: Ozone.

* * * * *

(ff) * * *

(10) Approval—On December 14, 2009, the Ohio Environmental Protection Agency submitted a request to redesignate the Ohio portion of the Cincinnati-Hamilton, OH–KY–IN area to attainment of the 8-hour ozone NAAQS. As part of the redesignation request, the State submitted a maintenance plan as required by section 175A of the Clean Air Act. Elements of the section 175 maintenance plan include a contingency plan and an obligation to submit a subsequent maintenance plan revision in 8 years as required by the Clean Air Act. The 2015 motor vehicle emissions budgets for the Ohio and Indiana portions of the Cincinnati-Hamilton, OH–KY–IN area are 31.73 tpd for VOC and 49.00 tpd for NO_X. The 2020 motor vehicle emissions budgets for the Ohio and Indiana portions of the area are 28.82 tpd for VOC and 34.39 tpd for NO_X.

* * * * *

(hh) * * *

(3) Approval—Ohio's 2005 inventory satisfies the base year emissions inventory requirements of section 172(c)(3) of the Clean Air Act for the Ohio portion of the Cincinnati-Hamilton, OH–KY–IN area under the 1997 8-hour ozone standard.

PART 81—[AMENDED]

■ 4. The authority citation for part 81 continues to read as follows:

Authority: 42 U.S.C. 7401 *et seq.*

■ 5. Section 81.315 is amended by revising the entry for Cincinnati-Hamilton, OH–KY–IN in the table entitled "Indiana—Ozone (8-Hour Standard)" to read as follows:

§ 81.315 Indiana.

* * * * *

INDIANA—OZONE

[8-Hour standard]

Designated area	Designation [a]		Classification	
	Date [1]	Type	Date [1]	Type
* *	*	* *	*	*
Cincinnati-Hamilton, OH–KY–IN:				
Dearborn County (part)	May 11, 2010	Attainment		
* *	*	* *	*	*

[a] Includes Indian Country located in each county or area, except as otherwise specified.
[1] This date is June 15, 2004, unless otherwise noted.

RIN 2060–AO71

Regulation of Fuels and Fuel Additives: Alternative Affirmative Defense Requirements for Ultra-Low Sulfur Diesel and Gasoline Benzene Technical Amendment

AGENCY: Environmental Protection Agency (EPA).

ACTION: Direct final rule.

SUMMARY: EPA is issuing a direct final rule to amend the diesel sulfur regulations to allow refiners, importers, distributors, and retailers of highway diesel fuel the option to use an alternative affirmative defense if the Agency finds highway diesel fuel samples above the specified sulfur standard at retail facilities. This alternative defense consists of a comprehensive program of quality assurance sampling and testing that would cover all participating companies that produce and/or distribute highway diesel fuel if certain other conditions are met. The sampling and testing program would be carried out by an independent surveyor. The program would be conducted pursuant to a survey plan approved by EPA that is designed to achieve the same objectives as the current regulatory quality assurance requirement. This rule also amends the gasoline benzene regulations to allow disqualified small refiners the same opportunity to generate gasoline benzene credits as that afforded to non-small refiners.

DATES: This rule is effective on July 12, 2010 without further notice, unless EPA receives adverse comment by June 10, 2010. If EPA receives adverse comment, we will publish a timely withdrawal in the **Federal Register** informing the public that this rule, or the relevant provisions of this rule, will not take effect. The incorporation by reference of a certain publication listed in the regulations is approved by the Director of the Federal Register as of July 12, 2010.

Hearings: If EPA receives a request from a person wishing to speak at a public hearing by May 26, 2010, a public hearing will be held at a time and location to be announced in a subsequent **Federal Register** notice. To request to speak at a public hearing, send a request to the contact in **FOR FURTHER INFORMATION CONTACT**.

ADDRESSES: Submit your comments, identified by Docket ID No. EPA–HQ–OAR–2007–1158, by one of the following methods:

- *http://www.regulations.gov:* Follow the on-line instructions for submitting comments.
- *E-mail: a-and-r-docket@epa.gov.*
- *Fax:* (202) 566–9744.
- *Mail:* Air and Radiation Docket, Environmental Protection Agency, Mailcode: 2822T, 1200 Pennsylvania Ave., NW., Washington, DC 20460.
- *Hand Delivery:* EPA Docket Center, Room 3334, EPA West Building, 1301 Constitution Avenue, NW., Washington, DC, Attention Air Docket ID No. EPA–HQ–OAR–2007–1158. Such deliveries are only accepted during the Docket's normal hours of operation, and special arrangements should be made for deliveries of boxed information.

Instructions: Direct your comments to Docket ID No. EPA–HQ–OAR–2007–1158. EPA's policy is that all comments received will be included in the public docket without change and may be made available online at *http://www.regulations.gov,* including any personal information provided, unless the comment includes information claimed to be Confidential Business Information (CBI) or other information whose disclosure is restricted by statute. Do not submit information that you consider to be CBI or otherwise protected through *http://www.regulations.gov* or e-mail. The *http://www.regulations.gov* Web site is an "anonymous access" system, which means EPA will not know your identity or contact information unless you provide it in the body of your comment. If you send an e-mail comment directly to EPA without going through *http://www.regulations.gov,* your e-mail address will automatically be captured and included as part of the comment that is placed in the public docket and made available on the Internet. If you submit an electronic comment, EPA recommends that you include your name and other contact information in the body of your comment and with any disk or CD–ROM you submit. If EPA cannot read your comment due to technical difficulties and cannot contact you for clarification, EPA may not be able to consider your comment. Electronic files should avoid the use of special characters, any form of encryption, and be free of any defects or viruses. For additional information about EPA's public docket, visit the EPA Docket Center homepage at *http://www.epa.gov/epahome/dockets.htm.*

Docket: All documents in the docket are listed in the *http://www.regulations.gov* index. Although listed in the index, some information is not publicly available, *e.g.,* CBI or other information whose disclosure is restricted by statute. Certain other material, such as copyrighted material, will be publicly available only in hard copy. Publicly available docket materials are available either electronically in www.regulations.gov or in hard copy at the Air Docket, EPA/DC, EPA West, Room 3334, 1301 Constitution Ave., NW., Washington, DC. The Public Reading Room is open from 8:30 a.m. to 4:30 p.m., Monday through Friday, excluding legal holidays. The telephone number for the Public Reading Room is (202) 566–1744, and the telephone number for the Air Docket is (202) 566–1742.

FOR FURTHER INFORMATION CONTACT: Jaimee Dong, Compliance and Innovative Strategies Division, Office of Transportation and Air Quality, Office of Air and Radiation, Environmental Protection Agency, Mail Code 6405J, 1200 Pennsylvania Avenue, Washington, DC 20460; telephone number: (202) 343–9672; fax number: (202) 343–2800; e-mail address: *Dong.Jaimee@epa.gov.*

SUPPLEMENTARY INFORMATION:

Why is EPA using a direct final rule?

EPA is publishing this rule without a prior proposed rule because we view this as a noncontroversial action and anticipate no adverse comment. However, in the "Proposed Rules" section of today's **Federal Register,** we are publishing a separate document that will serve as the proposed rule to amend the diesel sulfur regulations and the gasoline benzene regulations if adverse comments are received on this direct final rule. We do not intend to institute a second comment period on this action. Any parties interested in commenting must do so at this time. For further information about commenting on this rule, see the **ADDRESSES** section of this document.

If EPA receives adverse comment on a distinct provision of this rulemaking, we will publish a timely withdrawal in the **Federal Register** indicating which provisions we are withdrawing. The provisions that are not withdrawn will become effective on the date set out above, notwithstanding adverse comment on any other provision. We will address all public comments in any subsequent final rule based on the proposed rule.

abuse, Foreign relations, Government contracts, Grant programs—health, Grant programs—veterans, Health care, Health facilities, Health professions, Health records, Homeless, Medical and dental schools, Medical devices, Medical research, Mental health programs, Nursing homes, Philippines, Reporting and recordkeeping requirements, Scholarships and fellowships, Travel and transportation expenses, Veterans.

Dated: May 6, 2010.

Robert C. McFetridge,

Director, Regulation Policy and Management, Office of the General Counsel.

For the reasons stated in the preamble, VA proposes to amend 38 CFR part 17 as follows:

PART 17—MEDICAL

1. The authority citation for part 17 continues to read as follows:

Authority: 38 U.S.C. 501, 1721, and as noted in specific sections.

2. Amend § 17.38 by revising paragraph (c)(5) to read as follows:

§ 17.38 Medical benefits package.

* * * * *

(c) * * *

(5) Hospital and outpatient care for a veteran who is either a patient or inmate in an institution of another government agency if that agency has a duty to give the care or services. This exclusion does not apply to veterans who are released from incarceration in a prison or jail into a temporary housing program (such as a community residential re-entry center or halfway house).

BILLING CODE P

ENVIRONMENTAL PROTECTION AGENCY

40 CFR Parts 52 and 81

[EPA–R04–OAR–2010–0134–201007; FRL–9150–1]

Approval and Promulgation of Implementation Plans and Designation of Areas for Air Quality Planning Purposes; Kentucky; Redesignation of the Kentucky Portion of the Cincinnati-Hamilton 1997 8-Hour Ozone Nonattainment Area to Attainment

AGENCY: Environmental Protection Agency (EPA).

ACTION: Proposed rule.

SUMMARY: On January 29, 2010, the Commonwealth of Kentucky, through the Kentucky Energy and Environment Cabinet, Division for Air Quality (DAQ), submitted a request to redesignate the Kentucky portion of the tri-state Cincinnati-Hamilton 8-hour ozone nonattainment area (the "tri-state Cincinnati-Hamilton Area") to attainment for the 1997 8-hour ozone national ambient air quality standards (NAAQS); and to approve the state implementation plan (SIP) revision containing a maintenance plan for the Kentucky portion of the tri-state Cincinnati-Hamilton Area. The tri-state Cincinnati-Hamilton 1997 8-hour ozone nonattainment area is composed of Boone, Campbell and Kenton Counties in Kentucky (hereafter also referred to as "Northern Kentucky"); Butler, Clermont, Clinton, Hamilton and Warren Counties in Ohio; and a portion of Dearborn County in Indiana. In this action, EPA is proposing to: Determine that the tri-state Cincinnati-Hamilton Area has attained the 1997 8-hour ozone NAAQS; approve Kentucky's redesignation request for Boone, Campbell and Kenton Counties in Kentucky as part of the tri-state Cincinnati Area; approve the 1997 8-hour ozone maintenance plan for Northern Kentucky, including the motor vehicle emission budgets (MVEBs) for nitrogen oxides (NO_X) and volatile organic compounds (VOC) for the years 2015 and 2020; and approve the 2008 emissions inventory for Northern Kentucky as meeting the requirements of the Clean Air Act (CAA). EPA's proposed approval of Kentucky's redesignation request is based on the belief that Kentucky's request meets the criteria for redesignation to attainment specified in the CAA, including the determination that the entire tri-state Cincinnati-Hamilton ozone nonattainment area has attained the 1997 8-hour ozone NAAQS. In a separate rulemaking action, EPA has proposed to approve redesignation requests and maintenance plans submitted by Ohio and Indiana for their respective portions of this 1997 8-hour ozone area.

In this action, EPA is also notifying the public of the status of EPA's adequacy determination for the new 2015 and 2020 MVEBs that are contained in the 1997–8-hour ozone maintenance plan for Northern Kentucky. MVEBs for the Ohio and Indiana portions of this Area are included in the Ohio and Indiana submittals, and are being addressed through EPA's separate action for those submissions. EPA is also in the process of rulemaking on a new 8-hour ozone NAAQS. Today's actions, however, relate only to the 1997 8-hour ozone NAAQS.

DATES: Comments must be received on or before June 11, 2010.

ADDRESSES: Submit your comments, identified by Docket ID No. EPA–R04–OAR–2010–0134, by one of the following methods:

1. *http://www.regulations.gov:* Follow the on-line instructions for submitting comments.

2. *E-mail: benjamin.lynorae@epa.gov.*

3. *Fax:* (404) 562–9019.

4. *Mail:* EPA–R04–OAR–2010–0134, Regulatory Development Section, Air Planning Branch, Air, Pesticides and Toxics Management Division, U.S. Environmental Protection Agency, Region 4, 61 Forsyth Street, SW., Atlanta, Georgia 30303–8960.

5. *Hand Delivery or Courier:* Ms. Lynorae Benjamin, Chief, Regulatory Development Section, Air Planning Branch, Air, Pesticides and Toxics Management Division, U.S. Environmental Protection Agency, Region 4, 61 Forsyth Street, SW., Atlanta, Georgia 30303–8960. Such deliveries are only accepted during the Regional Office's normal hours of operation. The Regional Office's official hours of business are Monday through Friday, 8:30 to 4:30, excluding Federal holidays.

Instructions: Direct your comments to Docket ID No. EPA–R04–OAR–2010–0134. EPA's policy is that all comments received will be included in the public docket without change and may be made available online at *http://www.regulations.gov,* including any personal information provided, unless the comment includes information claimed to be Confidential Business Information (CBI) or other information whose disclosure is restricted by statute. Do not submit through *http://www.regulations.gov* or e-mail, information that you consider to be CBI or otherwise protected. The *http://www.regulations.gov* Web site is an "anonymous access" system, which means EPA will not know your identity or contact information unless you provide it in the body of your comment. If you send an e-mail comment directly to EPA without going through *http://www.regulations.gov,* your e-mail address will be automatically captured and included as part of the comment that is placed in the public docket and made available on the Internet. If you submit an electronic comment, EPA recommends that you include your name and other contact information in the body of your comment and with any disk or CD–ROM you submit. If EPA cannot read your comment due to

technical difficulties and cannot contact you for clarification, EPA may not be able to consider your comment. Electronic files should avoid the use of special characters, any form of encryption, and be free of any defects or viruses. For additional information about EPA's public docket visit the EPA Docket Center homepage at *http://www.epa.gov/epahome/dockets.htm.*

Docket: All documents in the electronic docket are listed in the *http://www.regulations.gov* index. Although listed in the index, some information is not publicly available, *i.e.,* CBI or other information whose disclosure is restricted by statute. Certain other material, such as copyrighted material, is not placed on the Internet and will be publicly available only in hard copy form. Publicly available docket materials are available either electronically in *http://www.regulations.gov* or in hard copy at the Regulatory Development Section, Air Planning Branch, Air, Pesticides and Toxics Management Division, U.S. Environmental Protection Agency, Region 4, 61 Forsyth Street, SW., Atlanta, Georgia 30303–8960. EPA requests that if at all possible, you contact the person listed in the **FOR FURTHER INFORMATION CONTACT** section to schedule your inspection. The Regional Office's official hours of business are Monday through Friday, 8:30 to 4:30, excluding Federal holidays.

FOR FURTHER INFORMATION CONTACT: Ms. Jane Spann or Mr. Zuri Farngalo of the Regulatory Development Section, in the Air Planning Branch, Air, Pesticides and Toxics Management Division, U.S. Environmental Protection Agency, Region 4, 61 Forsyth Street, SW., Atlanta, Georgia 30303–8960. Jane Spann may be reached by phone at (404) 562–9029, or via electronic mail at *spann.jane@epa.gov.* The telephone number for Mr. Farngalo is (404) 562–9152, and the electronic mail is *farngalo.zuri@epa.gov.*

SUPPLEMENTARY INFORMATION:

Table of Contents

I. What proposed actions is EPA taking?

EPA is proposing several related actions, which are summarized below and described in greater detail throughout this notice of rulemaking: (1) To determine that the tri-state Cincinnati-Hamilton Area has attained the 1997 8-hour ozone NAAQS; (2) to approve the Commonwealth of Kentucky's request to redesignate the Kentucky portion of the tri-state Cincinnati-Hamilton 1997 8-hour ozone nonattainment area (Boone, Campbell and Kenton Counties in Kentucky) to attainment for the 1997 8-hour ozone NAAQS under section 107(d)(3)(E) of the CAA; (3) to approve under section 172(c)(3) the emissions inventory submitted with the maintenance plan; and (4) to approve under section 175A Kentucky's 1997 8-hour ozone NAAQS maintenance plan into the Kentucky SIP, including the associated MVEBs. These proposed actions will be revisions to the Kentucky SIP pursuant to section 110 of the CAA. In addition, and related to today's actions, EPA is also notifying the public of the status of EPA's adequacy determination for the Northern Kentucky MVEBs.

First, EPA is proposing to determine that the tri-state Cincinnati-Hamilton Area has attained the 1997 8-hour ozone NAAQS, based on the most recent three years of complete, quality assured monitoring data. EPA further proposes to determine that the Area has met the requirements for redesignation under section 107(d)(3)(E) of the CAA if EPA's proposed approval of the emissions inventory for Northern Kentucky is finalized. In a separate action, EPA has proposed approval of the redesignation requests and maintenance plans for the Ohio and Indiana portions of the tri-state Cincinnati-Hamilton Area (75 FR 8871, February 26, 2010). In this action, EPA is now proposing to approve a request to redesignate the Kentucky portion of the Area and to change the legal designation of Boone, Campbell and Kenton Counties in Kentucky from nonattainment to attainment for the 1997 8-hour ozone NAAQS.

Second, EPA is proposing to approve under section 172(c)(3) Kentucky's 2008 emissions inventory included in the maintenance plan for Northern Kentucky as meeting the requirements of that section. In coordination with Ohio and Indiana, Kentucky selected 2008 as "the attainment year" for the tri-state Cincinnati-Hamilton Area for the purpose of demonstrating attainment of the 1997 8-hour ozone NAAQS. This emissions inventory identifies the level of emissions in the Area, which is sufficient to attain the 1997 8-hour ozone NAAQS. Please see section IX of this rulemaking for more detail on Kentucky's 2008 emission inventory.

Third, EPA is proposing to approve Kentucky's 1997 8-hour ozone NAAQS maintenance plan for Northern Kentucky as meeting the requirements of section 175A of the CAA, such approval being one of the CAA criteria for redesignation to attainment. The maintenance plan is designed to help keep the tri-state Cincinnati-Hamilton Area in attainment of the 1997 8-hour ozone NAAQS through 2020. Consistent with the CAA, the maintenance plan that EPA is proposing to approve today also includes 2015 and 2020 NO_X and VOC MVEBs. EPA is proposing to approve (into the Kentucky's SIP) the 2015 and 2020 MVEBs that are included as part of Kentucky's maintenance plan for the 1997 8-hour ozone NAAQS. The adequacy comment period for these MVEBs closed on March 5, 2010, and EPA did not receive any comments. (See section VIII of this proposed rulemaking.) Notably, these MVEBs apply only to Northern Kentucky. MVEBs contained in the Ohio's and Indiana's submittals for the remainder of the tri-state Cincinnati Area were addressed in a separate action (75 FR 8871, February 26, 2010).

EPA is also notifying the public of the status of EPA's adequacy process for the newly-established 2015 and 2020 NO_X and VOC MVEBs for Northern Kentucky. The MVEBs for the Ohio and Indiana portions of this 1997 8-hour ozone area are being addressed in a separate action. The Adequacy comment period for the Northern Kentucky 2015 and 2020 MVEBs began on February 3, 2010, with EPA's posting of the availability of this submittal on EPA's Adequacy Web site (*http://www.epa.gov/otaq/stateresources/transconf/currsips.htm*). The adequacy comment period for these MVEBs closed on March 5, 2010. EPA did not receive any adverse comments or requests for Kentucky's submission. Please see section VIII of this proposed rulemaking for further explanation of this process, and for more details on the MVEBs determination.

Today's notice of proposed rulemaking is in response to Kentucky's January 29, 2010, SIP submittal requesting the redesignation of Boone, Campbell and Kenton Counties in Kentucky as part of the tri-state Cincinnati-Hamilton 1997 8-hour ozone area, and includes SIP revisions

addressing the specific issues summarized above and the necessary elements for redesignation described in sections 107(d)(3)(E) and 175A of the CAA.

II. What is the background for EPA's proposed actions?

Ground-level ozone is not emitted directly by sources. Rather, emissions of NO_X and VOC react in the presence of sunlight to form ground-level ozone. NO_X and VOC are referred to as precursors of ozone. The CAA establishes a process for air quality management through the NAAQS.

On July 18, 1997, EPA promulgated a revised 8-hour ozone standard of 0.08 parts per million (ppm). This standard is more stringent than the previous 1-hour ozone standard. Under EPA regulations at 40 CFR part 50, the 1997 8-hour ozone standard is attained when the 3-year average of the annual fourth-highest daily maximum 8-hour average ambient air quality ozone concentrations is less than or equal to 0.08 ppm (0.084 ppm when rounding is considered). (*See* 69 FR 23857 (April 30, 2004) for further information.) Ambient air quality monitoring data for the 3-year period must meet a data completeness requirement. The ambient air quality monitoring data completeness requirement is met when the average percent of days with valid ambient monitoring data is greater than 90 percent, and no single year has less than 75 percent data completeness as determined in Appendix I of part 50. Specifically, section 2.3 of 40 CFR part 50, Appendix I, "*Comparisons with the Primary and Secondary Ozone Standards*" states:

"The primary and secondary ozone ambient air quality standards are met at an ambient air quality monitoring site when the 3-year average of the annual fourth-highest daily maximum 8-hour average ozone concentration is less than or equal to 0.08 ppm. The number of significant figures in the level of the standard dictates the rounding convention for comparing the computed 3-year average annual fourth-highest daily maximum 8-hour average ozone concentration with the level of the standard. The third decimal place of the computed value is rounded, with values equal to or greater than 5 rounding up. Thus, a computed 3-year average ozone concentration of 0.085 ppm is the smallest value that is greater than 0.08 ppm."

The CAA required EPA to designate as nonattainment any area that was violating the 1997 8-hour ozone NAAQS based on the three most recent years of ambient air quality data. The tri-state Cincinnati-Hamilton 1997 8-hour ozone nonattainment area was initially designated nonattainment for the 1997 8-hour ozone standard using 2001–2003 ambient air quality data. EPA published a final designations rulemaking for the NAAQS on April 30, 2004 (69 FR 23857).

Title I, Part D of the CAA contains two sets of provisions—subpart 1 and subpart 2—that address planning and control requirements for ozone nonattainment areas. Subpart 1 (which EPA refers to as "basic" nonattainment) contains general, less prescriptive, requirements for nonattainment areas for any pollutant—including ozone—governed by a NAAQS. Subpart 2 (which EPA refers to as "classified" nonattainment) provides more specific requirements for certain ozone nonattainment areas. Some 1997 8-hour ozone nonattainment areas were subject only to the provisions of subpart 1. Other 1997 8-hour ozone nonattainment areas were classified as subpart 2 areas and were subject to the provisions of subpart 2 in addition to subpart 1. Under EPA's Phase I 8-Hour Ozone Implementation Rule (69 FR 23857) (Phase I Rule), signed on April 15, 2004, and published April 30, 2004, an area was classified under subpart 2 based on its 8-hour ozone design value (*i.e.,* the 3-year average of the annual fourth highest daily maximum 8-hour average ozone concentrations), if it had a 1-hour design value at or above 0.121 ppm (the lowest 1-hour design value in Table 1 of subpart 2). All other areas were covered under subpart 1, based upon their 8-hour ambient air quality design values.

Northern Kentucky (as part of the bi-state Cincinnati-Hamilton Area) was originally designated as a moderate nonattainment area for the 1-hour ozone NAAQS on November 6, 1991 (56 FR 56694). On June 19, 2000 (65 FR 37879), the Kentucky portion of the Cincinnati-Hamilton 1-hour nonattainment area was redesignated as attainment for the 1-hour ozone NAAQS, and was considered to be a maintenance area subject to a CAA section 175A maintenance plan for the 1-hour NAAQS. On April 30, 2004, EPA designated the tri-state Cincinnati-Hamilton Area (which then included Boone, Campbell and Kenton Counties in Kentucky; Butler, Clermont, Clinton, Hamilton and Warren Counties in Ohio; and a portion of Dearborn County in Indiana) under subpart 1 as a "basic" 1997 8-hour ozone NAAQS nonattainment area (69 FR 23857, April 30, 2004).

As part of the 2004 designations, EPA also promulgated an implementation rule—the Phase I Rule. Various aspects of EPA's Phase I Rule were challenged in court. On December 22, 2006, the U.S. Court of Appeals for the District of Columbia Circuit (DC Circuit Court) vacated EPA's Phase I Rule (69 FR 23951, April 30, 2004). *South Coast Air Quality Management Dist. (SCAQMD)* v. *EPA,* 472 F.3d 882 (DC Cir. 2006). On June 8, 2007, in response to several petitions for rehearing, the DC Circuit Court clarified that the Phase I Rule was vacated only with regard to those parts of the Rule that had been successfully challenged. The Phase I Rule provisions related to classifications for areas currently classified under subpart 2 of title I, part D of the CAA as 1997 8-hour ozone NAAQS nonattainment areas, the 1997 8-hour ozone NAAQS attainment dates and the timing for emissions reductions needed for attainment of the 1997 8-hour ozone NAAQS remain effective. The June 8th decision left intact the Court's rejection of EPA's reasons for implementing the 1997 8-hour standard in certain nonattainment areas under subpart 1 in lieu of subpart 2. By limiting the vacatur, the Court let stand EPA's revocation of the 1-hour standard and those anti-backsliding provisions of the Phase I Rule that had not been successfully challenged. The June 8th decision affirmed the December 22, 2006, decision that EPA had improperly failed to retain measures required for 1-hour nonattainment areas under the anti-backsliding provisions of the regulations: (1) Nonattainment area New Source Review (NSR) requirements based on an area's 1-hour nonattainment classification; (2) Section 185 penalty fees for 1-hour severe or extreme nonattainment areas; and (3) measures to be implemented pursuant to section 172(c)(9) or 182(c)(9) of the CAA, on the contingency of an area not making reasonable further progress toward attainment of the 1-hour NAAQS, or for failure to attain that NAAQS. The June 8th decision clarified that the Court's reference to conformity requirements for anti-backsliding purposes was limited to requiring the continued use of 1-hour motor vehicle emissions budgets until 1997 8-hour ozone NAAQS budgets were available for 8-hour ozone conformity determinations, which is already required under EPA's conformity regulations. The Court thus clarified that 1-hour ozone conformity determinations are not required for anti-backsliding purposes.

For the reasons set forth below, EPA does not believe that the Court's rulings alter any requirements relevant to this redesignation action so as to preclude redesignation, nor does EPA believe the

Court's ruling prevents EPA from proposing or ultimately finalizing this redesignation. EPA believes that the Court's December 22, 2006, and June 8, 2007, decisions impose no impediment to moving forward with redesignation of Northern Kentucky to attainment, because even in light of the Court's decision, redesignation is appropriate under the relevant redesignation provisions of the CAA and longstanding policies regarding redesignation requests.

With respect to the 1997 8-hour ozone NAAQS, the Court's ruling rejected EPA's reasons for classifying areas under subpart 1 for the 1997 8-hour ozone NAAQS, and remanded that matter back to the Agency. In its January 16, 2009, proposed rulemaking in response to the *SCAQMD* decision, EPA has proposed to classify the tri-state Cincinnati-Hamilton Area (of which Northern Kentucky is a part) under subpart 2 as a moderate area (74 FR 2936). If EPA finalizes this rulemaking, the requirements under subpart 2 will become applicable when they are due. EPA proposed a deadline for submission of these requirements of one year after the effective date of the final rulemaking classifying this and other areas (74 FR 2940–2941). Although a future final decision by EPA to classify this Area under subpart 2 would trigger additional future requirements for the Area, EPA believes that this does not preclude this redesignation from being approved. This belief is based upon: (1) EPA's longstanding policy of evaluating requirements in accordance with the requirements due at the time redesignation request is submitted; and (2) consideration of the inequity of applying retroactively any requirements that might in the future be applied.

First, at the time the redesignation request was submitted, the tri-state Cincinnati-Hamilton Area was not classified under subpart 2, nor were subpart 2 requirements yet due for this Area. Under EPA's longstanding interpretation of section 107(d)(3)(E) of the CAA, to qualify for redesignation, states requesting redesignation to attainment must meet only the relevant SIP requirements that came due prior to the submittal of a complete redesignation request. September 4, 1992, Calcagni Memorandum ("Procedures for Processing Requests to Redesignate Areas to Attainment," Memorandum from John Calcagni, Director, Air Quality Management Division). *See also* Michael Shapiro Memorandum, September 17, 1993, and 60 FR 12459, 12465–66 (March 7, 1995) (Redesignation of Detroit-Ann Arbor, Michigan); *Sierra Club* v *EPA,* 375 F.3d 537 (7th Cir. 2004) (upholding this interpretation); 68 FR 25418, 25424, 25427 (May 12, 2003) (redesignation of St. Louis, Missouri).

Moreover, it would be inequitable to retroactively apply any new SIP requirements that were not applicable at the time the request was submitted. The DC Circuit Court has recognized the inequity in such retroactive rulemaking (*see Sierra Club* v. *Whitman* 285 F.3d 63 (DC Cir. 2002)), in which the Court upheld a district court's ruling refusing to make retroactive an EPA determination of nonattainment that was past the statutory due date. Such a determination would have resulted in the imposition of additional requirements on the area. The Court stated, "[a]lthough EPA failed to make the nonattainment determination within the statutory frame, Sierra Club's proposed solution only makes the situation worse. Retroactive relief would likely impose large costs on the states, which would face fines and suits for not implementing air pollution prevention plans in 1997, even though they were not on notice at the time." *Id.* at 68. Similarly here, it would be unfair to penalize the area by applying to it for purpose of redesignation, additional SIP requirements under subpart 2 that were not in effect or yet due at the time it submitted its redesignation request, or the time that the tri-state Cincinnati-Hamilton Area attained the standard.

With respect to the requirements under the 1-hour ozone NAAQS, Northern Kentucky had been redesignated attainment subject to a maintenance plan under section 175A. The DC Circuit Court's decisions do not impact redesignation requests for these types of areas, except to the extent that the Court, in its June 8th decision, clarified that for those areas with 1-hour MVEBs in their maintenance plans, anti-backsliding requires that those 1-hour budgets must be used for 8-hour conformity determinations until they are replaced by 1997 8-hour budgets. To meet this requirement, conformity determinations in such areas must comply with the applicable requirements of EPA's conformity regulations at 40 CFR part 93.

With regard to the anti-backsliding provisions for the 1-hour NAAQS that the DC Circuit Court found were not properly retained, Northern Kentucky is an attainment area subject to a maintenance plan for the 1-hour NAAQS, and 1-hour anti-backsliding requirements no longer apply to an area that is redesignated to attainment of the 1-hour ozone NAAQS. As a result, the decisions in *SCAQMD* should not alter any requirements that would preclude EPA from finalizing the redesignation of Northern Kentucky to attainment for the 1997 8-hour ozone NAAQS.

On January 29, 2010, Kentucky requested that EPA redesignate the Kentucky portion of the tri-state Cincinnati-Hamilton Area to attainment for the 1997 8-hour ozone NAAQS. The redesignation request included three years of complete, quality-assured ambient air quality data for the ozone seasons (March 1st through October 31st) of 2007–2009, demonstrating that the 1997 8-hour ozone NAAQS has been achieved for the entire tri-state Cincinnati-Hamilton Area. Under the CAA, nonattainment areas may be redesignated to attainment if EPA determines that the most recent three years of complete, quality-assured data show that the Area has attained the standard, and the Area meets the other redesignation requirements set forth in CAA section 107(d)(3)(E).

III. What are the Criteria for Redesignation?

The CAA provides the requirements for redesignating a nonattainment area to attainment. Specifically, section 107(d)(3)(E) of the CAA allows for redesignation providing that: (1) The Administrator determines that the area has attained the applicable NAAQS; (2) the Administrator has fully approved the applicable implementation plan for the area under section 110(k); (3) the Administrator determines that the improvement in air quality is due to permanent and enforceable reductions in emissions resulting from implementation of the applicable SIP and applicable Federal air pollutant control regulations and other permanent and enforceable reductions; (4) the Administrator has fully approved a maintenance plan for the area as meeting the requirements of section 175A; and (5) the state containing such area has met all requirements applicable to the area for purposes of redesignation under section 110 and part D of the CAA.

EPA provided guidance on redesignation in the General Preamble for the Implementation of title I of the CAA Amendments of 1990, on April 16, 1992 (57 FR 13498), and supplemented this guidance on April 28, 1992 (57 FR 18070). EPA has provided further guidance on processing redesignation requests in the following documents:

1. "Ozone and Carbon Monoxide Design Value Calculations," Memorandum from Bill Laxton, Director, Technical Support Division, June 18,1990;

2. "Maintenance Plans for Redesignation of Ozone and Carbon

Monoxide Nonattainment Areas," Memorandum from G. T. Helms, Chief, Ozone/Carbon Monoxide Programs Branch, April 30, 1992;

3. "Contingency Measures for Ozone and Carbon Monoxide (CO) Redesignations," Memorandum from G. T. Helms, Chief, Ozone/Carbon Monoxide Programs Branch, June 1, 1992;

4. "Procedures for Processing Requests to Redesignate Areas to Attainment," Memorandum from John Calcagni, Director, Air Quality Management Division, September 4, 1992 (hereafter referred to as the "Calcagni Memorandum");

5. "State Implementation Plan (SIP) Actions Submitted in Response to Clean Air Act (CAA) Deadlines," Memorandum from John Calcagni, Director, Air Quality Management Division, October 28, 1992;

6. "Technical Support Documents (TSDs) for Redesignation of Ozone and Carbon Monoxide (CO) Nonattainment Areas," Memorandum from G. T. Helms, Chief, Ozone/Carbon Monoxide Programs Branch, August 17, 1993;

7. "State Implementation Plan (SIP) Requirements for Areas Submitting Requests for Redesignation to Attainment of the Ozone and Carbon Monoxide (CO) National Ambient Air Quality Standards (NAAQS) On or After November 15, 1992," Memorandum from Michael H. Shapiro, Acting Assistant Administrator for Air and Radiation, September 17, 1993;

8. "Use of Actual Emissions in Maintenance Demonstrations for Ozone and CO Nonattainment Areas," Memorandum from D. Kent Berry, Acting Director, Air Quality Management Division, November 30, 1993;

9. "Part D New Source Review (Part D NSR) Requirements for Areas Requesting Redesignation to Attainment," Memorandum from Mary D. Nichols, Assistant Administrator for Air and Radiation, October 14, 1994; and

10. "Reasonable Further Progress, Attainment Demonstration, and Related Requirements for Ozone Nonattainment Areas Meeting the Ozone National Ambient Air Quality Standard," Memorandum from John S. Seitz, Director, Office of Air Quality Planning and Standards, May 10, 1995.

IV. Why is EPA proposing these actions?

On January 29, 2010, Kentucky requested redesignation of Northern Kentucky (as part of the tri-state Cincinnati-Hamilton 1997 8-hour ozone nonattainment area) to attainment for the 1997 8-hour ozone NAAQS. EPA's preliminary evaluation indicates that the tri-state Cincinnati-Hamilton Area has attained the 1997 8-hour ozone NAAQS and that Northern Kentucky, upon final approval of its 2008 emissions inventory, meets the requirements for redesignation set forth in section 107(d)(3)(E), including the maintenance plan requirements under section 175A of the CAA. EPA is also proposing to approve the 2008 baseline emission inventory because EPA believes that it satisfies the requirements of section 172(c)(3). EPA is finding that the 2015 and 2020 NO_X and VOC MVEBs which are included in the maintenance plan are adequate, and EPA is proposing to approve them along with the requested redesignation.

V. What is the effect of EPA's proposed actions?

EPA's proposed actions establish the basis upon which EPA may take final action on the issues being proposed for approval today. Approval of Kentucky's redesignation request would change the legal designation of the Kentucky portion of the tri-state Cincinnati-Hamilton 1997 8-hour ozone nonattainment area (Boone, Campbell and Kenton Counties) from nonattainment to attainment for the 1997 8-hour ozone NAAQS. 40 CFR part 81. It would also incorporate into the Kentucky SIP a plan for Northern Kentucky to maintain the 1997 8-hour ozone NAAQS in the Area through 2020. This maintenance plan includes contingency measures to remedy future violations of the 1997 8-hour ozone NAAQS. The maintenance plan also includes NO_X and VOC MVEBs for Northern Kentucky, and final approval of the MVEB's would establish them in the approved SIP. Table 1 identifies the state NO_X and VOC MVEBs for the years 2015 and 2020 for Northern Kentucky.

TABLE 1—NORTHERN KENTUCKY 1997 8-HOUR OZONE NO_X AND VOC MVEBS

[Summer season tons per day]

	2015	2020
NO_X	14.40	13.27
VOC	9.76	10.07

Approval of Kentucky's maintenance plan would also result in approval of the NO_X and VOC MVEBs. Additionally, EPA is notifying the public of the status of its adequacy determination for the 2015 and 2020 NO_X and VOC state MVEBs pursuant to 40 CFR 93.118(f)(1). A final approval of EPA's proposed action with respect to the 2008 emissions inventory would also result in approval of that inventory under section 172(c)(3).

VI. What is EPA's analysis of the request?

EPA is proposing to make the determination that the tri-state Cincinnati-Hamilton 1997 8-hour ozone nonattainment area has attained the 1997 8-hour ozone standard, and that all other redesignation criteria have been met for the Kentucky portion of the tri-state Cincinnati-Hamilton Area. The basis for EPA's determination for the Area is discussed in greater detail below.

Criteria (1)—*The Area has attained the 1997 8-hour ozone NAAQS.*

EPA is proposing to determine that the tri-state Cincinnati-Hamilton Area has attained the 1997 8-hour ozone NAAQS. An area may be considered to be attaining the 1997 8-hour ozone NAAQS if as determined in accordance with 40 CFR 50.10 and Appendix I of part 50, it meets the NAAQS based on three complete, consecutive calendar years of quality-assured air quality monitoring data. To attain the standard, the 3-year average of the fourth-highest daily maximum 8-hour average ozone concentrations measured at each monitor within an area over each year must not exceed 0.08 ppm. Based on the data handling and reporting convention described in 40 CFR part 50, Appendix I, the standard is attained if the design value is 0.084 ppm or below. The data must be collected and quality-assured in accordance with 40 CFR part 58, and recorded in the EPA Air Quality System (AQS). The monitors generally should have remained at the same location for the duration of the monitoring period required for demonstrating attainment.

EPA reviewed data from the ambient ozone monitoring stations in the tri-state

Cincinnati-Hamilton Area for the ozone seasons from 2007–2009. These data have been quality-assured and certified, and are recorded in AQS. The fourth-highest 8-hour ozone average for 2007, 2008 and 2009, and the 3-year average of these values (*i.e.,* design values), are summarized in the following table:

TABLE 2—ANNUAL 4TH MAX HIGH AND DESIGN VALUE CONCENTRATION FOR 8-HOUR OZONE FOR THE CINCINNATI-HAMILTON OH–KY–IN AREA

[Parts per million]

State*	County	Monitor	2007 4th high (ppm)	2008 4th high (ppm)	2009 4th high (ppm)	2007–2009 average (ppm)
Ohio	Butler	Hamilton, 39–017–0004	0.091	0.071	0.073	0.078
		Middletown, 39–017–1004	0.091	0.079	0.076	0.082
	Clermont	Batavia, 39–025–0022	0.086	0.071	0.069	0.075
	Clinton	Wilmington, 39–027–1022	0.082	0.076	0.070	0.076
	Hamilton	Grooms Rd., Cincinnati, 39–061–0006.	0.089	0.086	0.072	0.082
		Cleves, 39–061–0010	0.086	0.077	0.065	0.076
		250 Wm. Howard Taft, Cincinnati, 39–061–0040.	0.086	0.080	0.074	0.080
	Warren	Lebanon, 39–165–0007	0.088	0.082	0.077	0.082
Kentucky	Boone	KY 338 & Lower River Road, 21–037–3002.	0.078	0.064	0.064	0.068
	Campbell	Highland Heights, 21–117–0007	0.086	0.075	0.068	0.076
	Kenton	Covington, 21–117–0007	0.085	0.073	0.074	0.077

*There is no monitor in the Indiana portion of this Area.

As discussed above, the design value for an area is the highest 3-year average of the annual fourth-highest 8-hour ozone value recorded at any monitor in the Area. Therefore, the most recent 3-year design value (2007–2009) for the tri-state Cincinnati-Hamilton Area is 0.082 ppm, which meets the standard as described above. Currently available data show that the Area continues to attain the NAAQS. If the Area does not continue to attain until EPA finalizes the redesignation, EPA will not go forward with the redesignation. As discussed in more detail below, Kentucky has committed to continue monitoring in this Area in accordance with 40 CFR part 58. EPA proposes to find that the tri-state Cincinnati-Hamilton Area has attained the 1997 8-hour ozone NAAQS.

Criteria (2)—*Kentucky has a fully approved SIP under section 110(k) for Northern Kentucky and* Criteria (5)—*Kentucky has met all Applicable Requirements under Section 110 and part D of the CAA.*

Below is a summary of how these two criteria were met.

EPA proposes to find that Kentucky has met all applicable SIP requirements for Northern Kentucky under section 110 of the CAA (general SIP requirements) for purposes of redesignation. EPA also proposes to find that, if EPA finalizes approval of the 2008 emissions inventory submitted with the redesignation request, the Kentucky SIP satisfies the criterion that it meet applicable SIP requirements for purposes of redesignation under part D of title I of the CAA (requirements specific to subpart 1 nonattainment areas) in accordance with section 107(d)(3)(E)(v). In addition, EPA proposes to determine that, upon final approval of the emissions inventory, the SIP is fully approved with respect to all requirements applicable for purposes of redesignation in accordance with section 107(d)(3)(E)(ii). In making these determinations, EPA ascertained which requirements are applicable to the Area and that if applicable, they are fully approved under section 110(k). SIPs must be fully approved only with respect to applicable requirements. As discussed more fully below, SIPs must be fully approved only with respect to requirements that became due prior to the submission of the redesignation request.

a. Northern Kentucky has met all Applicable Requirements under section 110 and part D of the CAA.

The September 4, 1992, Calcagni Memorandum describes EPA's interpretation of section 107(d)(3)(E). Under this interpretation, to qualify for redesignation, states requesting redesignation to attainment must meet only the relevant CAA requirements that come due prior to the submittal of a complete redesignation request. See also Michael Shapiro Memorandum, ("SIP Requirements for Areas Submitting Requests for Redesignation to Attainment of the Ozone and Carbon Monoxide NAAQS On or After November 15, 1992," September 17, 1993); 60 FR 12459, 12465–66 (March 7, 1995) (redesignation of Detroit-Ann Arbor, Michigan). Applicable requirements of the CAA that come due subsequent to the area's submittal of a complete redesignation request remain applicable until a redesignation is approved, but are not required as a prerequisite to redesignation. *See* section 175A(c) of the CAA; *Sierra Club,* 375 F.3d 537; *see also* 68 FR 25424, 25427 (May 12, 2003) (redesignation of St. Louis, Missouri).

If EPA's proposed determination of attainment for the tri-state Cincinnati-Hamilton Area is finalized, under 40 CFR 51.918, if that determination is finalized, the requirements to submit certain planning SIPs related to attainment, including attainment demonstration requirements (the RACM requirement of section 172(c)(1) of the CAA, the RFP and attainment demonstration requirements of sections 172(c)(2) and (c)(6) of the CAA, and the requirement for contingency measures of section 172(c)(9) of the CAA) would not be applicable to the Area so long as it continues to attain the NAAQS and would cease to apply upon redesignation. In addition, in the context of redesignations, EPA has interpreted requirements related to attainment as not applicable for purposes of redesignations. For example, in the General Preamble, EPA stated that:

> [t]he section 172(c)(9) requirements are directed at ensuring RFP and attainment by the applicable date. These requirements no longer apply to an area that has attained the standard and is eligible for redesignation. Furthermore, section 175A for maintenance plans * * * provides specific requirements for contingency measures that effectively supersede the requirements of section

172(c)(9) for these areas. "General Preamble for the Interpretation of Title I of the Clean Air Act Amendments of 1990" ("General Preamble"), 57 FR 13498, 13564 (April 16, 1992).

See also Calcagni Memorandum at page 6 ("The requirements for reasonable further progress and other measures for attainment will not apply for redesignations because they only have meaning for areas not attaining the standard").

General SIP requirements. Section 110(a)(2) of title I of the CAA delineates the general requirements for a SIP, which include enforceable emissions limitations and other control measures, means, or techniques, provisions for the establishment and operation of appropriate devices necessary to collect data on ambient air quality, and programs to enforce the limitations. General SIP elements and requirements are delineated in section 110(a)(2) of title I, part A of the CAA. These requirements include, but are not limited to, the following: submittal of a SIP that has been adopted by the state after reasonable public notice and hearing; provisions for establishment and operation of appropriate procedures needed to monitor ambient air quality; implementation of a source permit program; provisions for the implementation of part C requirements (Prevention of Significant Deterioration (PSD)) and provisions for the implementation of part D requirements (NSR permit programs); provisions for air pollution modeling; and provisions for public and local agency participation in planning and emission control rule development.

Section 110(a)(2)(D) requires that SIPs contain certain measures to prevent sources in a state from significantly contributing to air quality problems in another state. To implement this provision, EPA has required certain states to establish programs to address the transport of air pollutants (NO_X SIP Call [1] and Clean Air Interstate Rule (CAIR) (70 FR 25162, May 12, 2005)). However, the section 110(a)(2)(D) requirements for a state are not linked with a particular nonattainment area's designation and classification in that state. EPA believes that the requirements linked with a particular nonattainment area's designation and classifications are the relevant measures to evaluate in reviewing a redesignation request. The transport SIP submittal requirements, where applicable, continue to apply to a state regardless of the designation of any one particular area in the state. Thus, we do not believe that the CAA's interstate transport requirements should be construed to be applicable requirements for purposes of redesignation.

In addition, EPA believes that the other section 110 elements not connected with nonattainment plan submissions and not linked with an area's attainment status are not applicable requirements for purposes of redesignation. A state remains subject to these requirements after an area is redesignated to attainment. The section 110 and part D requirements, which are linked with a particular area's designation and classification, are the relevant measures to evaluate in reviewing a redesignation request. This approach is consistent with EPA's existing policy on applicability (*i.e.,* for redesignations) of conformity and oxygenated fuels requirements, as well as with section 184 ozone transport requirements. See Reading, Pennsylvania, proposed and final rulemakings (61 FR 53174–53176, October 10, 1996), (62 FR 24826, May 7, 1997); Cleveland-Akron-Loraine, Ohio, final rulemaking (61 FR 20458, May 7, 1996); and Tampa, Florida, final rulemaking at (60 FR 62748, December 7, 1995). See also the discussion on this issue in the Cincinnati, Ohio redesignation (65 FR 37890, June 19, 2000), and in the Pittsburgh, Pennsylvania redesignation (66 FR 50399, October 19, 2001).

EPA believes that section 110 elements not linked to the Area's nonattainment status are not applicable for purposes of redesignation. Therefore, as was discussed above, for purposes of redesignation, they are not considered applicable requirements. Nonetheless, EPA notes it has previously approved provisions in the Kentucky SIP addressing section 110 elements under the 1-hour ozone NAAQS (65 FR 37879, June 19, 2000) The Commonwealth believes that the section 110 SIP approved for the 1-hour ozone NAAQS are sufficient to meet the requirements under the 1997 8-hour ozone NAAQS. The Commonwealth has submitted a letter dated December 10, 2007, setting forth its belief that the section 110 SIP approved for the 1-hour ozone NAAQS is also sufficient to meet the requirements under the 1997 8-hour ozone NAAQS. EPA has not yet approved this submission, but such approval is not necessary for purposes of redesignation.

Part D requirements. EPA proposes that if EPA approves the Commonwealth's base year emissions inventory, which is part of the maintenance plan submittal, the Kentucky SIP will meet applicable SIP requirements under part D of the CAA. We believe the emissions inventory is approvable because the 2008 VOC and NO_X emissions for Northern Kentucky were developed consistent with EPA guidance for emission inventories and the choice of the 2008 base year is appropriate because it represents the 2007–2009 period when the 1997 8 hour ozone NAAQS was not violated.

Part D, subpart 1 applicable SIP requirements. EPA has determined that, if EPA finalizes the approval of the base year emissions inventories discussed in section IX. of this rulemaking, the Kentucky SIP will meet the applicable SIP requirements for their portions of the tri-state Cincinnati-Hamilton Area applicable for purposes of redesignation under part D of the CAA. Subpart 1 of part D, found in sections 172–176 of the CAA, sets for the basic nonattainment requirements applicable to all nonattainment areas. Subpart 2 of part D, which includes section 182 of the CAA, establishes additional specific requirements depending on the area's nonattainment classification. Since the tri-state Cincinnati-Hamilton Area (of which Northern Kentucky is a part) was not classified under subpart 2 at the time the redesignation request was submitted, the subpart 2 requirements do not apply for purposes of evaluating the Commonwealth's redesignation request. The applicable subpart 1 requirements are contained in sections 172(c)(1)–(9) and in section 176.

For purposes of evaluating this redesignation request, the applicable part D, subpart 1 SIP requirements for all nonattainment areas are contained in sections 172–176. A thorough discussion of the requirements contained in section 172 can be found in the General Preamble for Implementation of title I (57 FR 13498).

Subpart 1 Section 172 Requirements. For purposes of evaluating this redesignation request, the applicable section 172 SIP requirements for the tri-state Cincinnati-Hamilton area are contained in sections 172(c)(1)–(9). A thorough discussion of the requirements contained in section 172 can be found in the General Preamble for Implementation of Title I (57 FR 13498, April 16, 1992).

Section 172(c)(1) requires the plans for all nonattainment areas to provide

[1] On October 27, 1998 (63 FR 57356), EPA issued a NO_X SIP Call requiring the District of Columbia and 22 states to reduce emissions of NO_X in order to reduce the transport of ozone and ozone precursors. In compliance with EPA's NO_X SIP Call, Kentucky has developed rules governing the control of NO_X emissions from Electric Generating Units (EGUs), major non-EGU industrial boilers, major cement kilns, and internal combustion engines. EPA approved Kentucky's rules as fulfilling Phase I and Phase II of the NO_X SIP Call on October 23, 2009 (74 FR 54755).

for the implementation of all RACM as expeditiously as practicable and to provide for attainment of the national primary ambient air quality standards. EPA interprets this requirement to impose a duty on all nonattainment areas to consider all available control measures and to adopt and implement such measures as are reasonably available for implementation in each area as components of the area's attainment demonstration. On December 7, 2007, the Commonwealth submitted an attainment demonstration and identified the control measures necessary to attain the NAAQS in the tri-state Cincinnati-Hamilton Area. Similar attainment demonstrations were submitted by Ohio and Indiana as part of the tri-state Cincinnati-Hamilton 1997 8-hour ozone nonattainment Area. However, because attainment has been reached, no additional measures are needed to provide for attainment, and section 172(c)(1) requirements are no longer considered to be applicable as long as the area continues to attain the standard until redesignation. 40 CFR 51.918. If EPA finalizes approval of the redesignation of the Kentucky portion of the tri-state Cincinnati-Hamilton Area, EPA will take no further action on the attainment demonstration submitted by the Commonwealth of Kentucky for this Area.

The RFP requirement under section 172(c)(2) is defined as progress that must be made toward attainment. This requirement is not relevant for purposes of redesignation because the tri-state Cincinnati-Hamilton Area has monitored attainment of the ozone NAAQS. (General Preamble, 57 FR 13564). *See also* 40 CFR 51.918. In addition, because the tri-state Cincinnati-Hamilton Area has attained the ozone NAAQS and is no longer subject to an RFP requirement, the requirement to submit the section 172(c)(9) contingency measures is not applicable for purposes of redesignation. *Id.*

Section 172(c)(3) requires submission and approval of a comprehensive, accurate and current inventory of actual emissions. As part of Kentucky's redesignation request for the tri-state Cincinnati-Hamilton Area, the Commonwealth submitted a 2008 base year emissions inventory. As discussed below in section IX., EPA is proposing to approve the 2008 base year inventory that Kentucky submitted with the redesignation request as meeting the section 172(c)(3) emissions inventory requirement.

Section 172(c)(4) requires the identification and quantification of allowable emissions for major new and modified stationary sources to be allowed in an area, and section 172(c)(5) requires source permits for the construction and operation of new and modified major stationary sources anywhere in the nonattainment area. EPA has determined that, since PSD requirements will apply after redesignation, areas being redesignated need not comply with the requirement that a NSR program be approved prior to redesignation, provided that the Area demonstrates maintenance of the NAAQS without part D NSR. A more detailed rationale for this view is described in a memorandum from Mary Nichols, Assistant Administrator for Air and Radiation, dated October 14, 1994, entitled, "Part D New Source Review Requirements for Areas Requesting Redesignation to Attainment." Kentucky has demonstrated that the tri-state Cincinnati-Hamilton Area will be able to maintain the standard without part D NSR in effect; therefore, EPA concludes that the Commonwealth need not have fully approved part D NSR programs prior to approval of the redesignation request. The Commonwealth's PSD programs will become effective in the tri-state Cincinnati-Hamilton Area upon redesignation to attainment. *See* rulemakings for Detroit, Michigan (60 FR 12467–12468, March 7, 1995); Cleveland-Akron-Lorain, Ohio (61 FR 20458, 20469–20470, May 7, 1996); Louisville, Kentucky (66 FR 53665, October 23, 2001); and Grand Rapids, Michigan (61 FR 31834–31837, June 21, 1996).

Section 172(c)(6) requires the SIP to contain control measures necessary to provide for attainment of the standard. Because attainment has been reached, no additional measures are needed to provide for attainment.

Section 172(c)(7) requires the SIP to meet the applicable provisions of section 110(a)(2). As noted above, we believe the Kentucky SIP meets the requirements of section 110(a)(2) applicable for purposes of redesignation.

Section 176 Conformity Requirements. Section 176(c) of the CAA requires states to establish criteria and procedures to ensure that federally-supported or funded projects conform to the air quality planning goals in the applicable SIP. The requirement to determine conformity applies to transportation plans, programs and projects developed, funded or approved under title 23 of the United States Code (U.S.C.) and the Federal Transit Act (transportation conformity) as well as to all other federally supported or funded projects (general conformity). State transportation conformity SIP revisions must be consistent with Federal conformity regulations relating to consultation, enforcement and enforceability that EPA promulgated pursuant to its authority under the CAA.

EPA believes it is reasonable to interpret the conformity SIP requirements [2] as not applying for purposes of evaluating the redesignation request under section 107(d) because state conformity rules are still required after redesignation and Federal conformity rules apply where state rules have not been approved. *See Wall,* 265 F.3d 426 (upholding this interpretation); See also 60 FR 62748 (December 7, 1995, Tampa, Florida). Kentucky submitted its transportation conformity SIP for 1997 8-hour ozone and particulate matter NAAQS on December 31, 2008. EPA proposed approval on December 4, 2009 (74 FR 63697) for Kentucky's transportation conformity SIP. EPA did not receive any comments for its proposed approval of Kentucky's transportation conformity SIP and is in the process of finalizing its action for this submission. Kentucky did not have a Federally-approved transportation conformity SIP for the 1-hour NAAQS, and thus approval of Kentucky's December 31, 2008, submittal will establish Kentucky's first Federally-approved transportation conformity SIP. However, conformity analyses are performed pursuant to EPA's Federal conformity rules.

NSR Requirements. EPA has also determined that areas being redesignated need not comply with the requirement that a NSR program be approved prior to redesignation, provided that the area demonstrates maintenance of the standard without a part D NSR program in effect since PSD requirements will apply after redesignation. The rationale for this view is described in a memorandum from Mary Nichols, Assistant Administrator for Air and Radiation, dated October 14, 1994, entitled "Part D New Source Review (Part D NSR) Requirements for Areas Requesting Redesignation to Attainment." Kentucky has demonstrated that Northern Kentucky (as part of the tri-state Cincinnati-Hamilton Area) will be able to maintain the standard without a part D NSR program in effect, and therefore, Kentucky need not have a fully-approved part D NSR program prior to approval of the redesignation request.

[2] CAA Section 176(c)(4)(E) requires states to submit revisions to their SIPs to reflect certain Federal criteria and procedures for determining transportation conformity. Transportation conformity SIPs are different from the motor vehicle emission budgets that are established in control strategy SIPs and maintenance plans.

However, Kentucky currently has a fully-approved part D NSR program in place. Kentucky has a fully-approved part D NSR program. Kentucky's PSD program will become effective in Northern Kentucky upon redesignation to attainment. *See* rulemakings for Detroit, Michigan (60 FR 12467–12468, March 7, 1995); Cleveland-Akron-Lorraine, Ohio (61 FR 20458, 20469–70, May 7, 1996); Louisville, Kentucky (66 FR 53665, October 23, 2001); and Grand Rapids, Michigan (61 FR 31834–31837, June 21, 1996). Thus, Northern Kentucky has satisfied all applicable requirements for purposes of redesignation under section 110 and part D of the CAA.

b. Northern Kentucky has a fully approved applicable SIP under section 110(k) of the CAA.

If EPA issues a final approval of the base year emissions inventories, EPA will have fully approved the applicable Kentucky SIP for the Kentucky portion of the tri-state Cincinnati-Hamilton 8-hour ozone nonattainment area, under section 110(k) of the CAA for all requirements applicable for purposes of redesignation. EPA may rely on prior SIP approvals in approving a redesignation request, see Calcagni Memorandum at p. 3; *Southwestern Pennsylvania Growth Alliance* v. *Browner,* 144 F.3d 984, 989–90 (6th Cir. 1998); *Wall,* 265 F.3d 426, plus any additional measures it may approve in conjunction with a redesignation action. See 68 FR 25426 (May 12, 2003) and citations therein. Following passage of the CAA of 1970, Kentucky has adopted and submitted, and EPA has fully approved at various times, provisions addressing the various 1-hour ozone NAAQS SIP elements applicable in the Cincinnati-Hamilton Area (65 FR 37879, June 19, 2000).

As indicated above, EPA believes that the section 110 elements not connected with nonattainment plan submissions and not linked to the area's nonattainment status are not applicable requirements for purposes of redesignation. EPA also believes that since the part D subpart 2 requirements did not become due prior to submission of the redesignation request, they also are therefore not applicable requirements for purposes of redesignation. *Sierra Club* v. *EPA,* 375 F.3d 537 (7th Cir. 2004); 68 FR 25424, 25427 (May 12, 2003) (redesignation of the St. Louis-East St. Louis Area to attainment of the 1-hour ozone NAAQS). With the approval of the emissions inventory, EPA will have approved all Part D subpart 1 requirements applicable for purposes of redesignation.

Criteria (3)—*The air quality improvement in the tri-state Cincinnati-Hamilton 1997 8-hour Ozone NAAQS Nonattainment Area is due to permanent and enforceable reductions in emissions resulting from implementation of the SIP and applicable Federal air pollution control regulations and other permanent and enforceable reductions.*

Measured reductions in ozone concentrations in and around Northern Kentucky are largely attributable to reductions from emission sources—in Kentucky as well as Ohio and Indiana—of VOC and NO_X, which are precursors in the formation of ozone. See 75 FR 8879. EPA believes that Kentucky has demonstrated that the observed air quality improvement in the tri-state Cincinnati-Hamilton Area is due to permanent and enforceable reductions in emissions resulting from implementation of the SIP, Federal measures, and other state adopted measures. Additionally, new emissions control programs for fuels and motor vehicles will help ensure a continued decrease in emissions throughout the region. The following is a discussion of permanent and enforceable measures that have been implemented in the Northern Kentucky Area.

i. *Stationary Source NO_X Rules.* Kentucky has developed rules governing the control of NO_X emissions from EGUs, major non-EGU industrial boilers, major cement kilns, and internal combustion engines. EPA approved Kentucky's rules as fulfilling Phase I and Phase II of the NO_X SIP Call on October 23, 2009 (74 FR 54755). Kentucky began complying with Phase I of this rule in 2004. Compliance with Phase II of the SIP Call, which requires the control NO_X emissions from large internal combustion engines, began in Kentucky in 2007, and resulted in a 41 percent NO_X reduction from 1995 to 2008 levels.

ii. *Federal Emission Control Measures.* Reductions in VOC and NO_X emissions have occurred statewide and in upwind areas as a result of Federal emission control measures, with additional emission reductions expected to occur in the future. Federal emission control measures include the following.

Tier 2 Emission Standards for Vehicles and Gasoline Sulfur Standards. These emission control requirements result in lower VOC and NO_X emissions from new cars and light duty trucks, including sport utility vehicles. The Federal rules were phased in between 2004 and 2009. EPA has estimated that, by the end of the phase-in period, the following vehicle NO_X emission reductions will occur nationwide: passenger cars (light duty vehicles) (77 percent); light duty trucks, minivans, and sports utility vehicles (86 percent); and, larger sports utility vehicles, vans, and heavier trucks (69 to 95 percent). VOC emission reductions are expected to range from 12 to 18 percent, depending on vehicle class, over the same period. Some of these emission reductions occurred by the attainment years (2007–2009) and additional emission reductions will occur during the maintenance period.

Heavy-Duty Diesel Engine Rule. EPA issued this rule in July 2000. This rule includes standards limiting the sulfur content of diesel fuel, which went into effect in 2004. A second phase took effect in 2007 which further reduced the highway diesel fuel sulfur content to 15 ppm, leading to additional reductions in combustion NO_X and VOC emissions. This rule is expected to achieve a 95 percent reduction in NO_X emissions from diesel trucks and busses.

Non-Road Diesel Rule. EPA issued this rule in 2004. This rule applies to diesel engines used in industries, such as construction, agriculture, and mining. It is estimated that compliance with this rule will cut NO_X emissions from non-road diesel engines by up to 90 percent. This rule is currently achieving emission reductions, but will not be fully implemented until 2010.

iii. *Control Measures in Upwind Areas.* On October 27, 1998 (63 FR 57356), EPA issued a NO_X SIP Call requiring the District of Columbia and 22 states to reduce emissions of NO_X. Affected states were required to comply with Phase I of the SIP Call beginning in 2004, and Phase II beginning in 2007. The reduction in NO_X emissions has resulted in lower concentrations of transported ozone entering the Cincinnati-Hamilton area. Emission reductions resulting from regulations developed in response to the NO_X SIP Call are permanent and enforceable.

Additional measures implemented by the Commonwealth of Kentucky which are providing emission reduction benefits for the Northern Kentucky Area:

- All new major VOC sources locating in Kentucky are subject to RACT;
- All major modifications to existing major VOC sources are subject to RACT requirements;
- Implementation of a program to enhance inspection of stationary sources to ensure emission control equipment is functioning properly;
- Requirements for Stage II vapor recovery;
- Federal Motor Vehicle Control Standards apply in Kentucky;
- Reformulated gasoline;

• Federal controls on VOC content for Architectural and Maintenance Paints, Auto Body Shops, and Consumer Products;

• Open burning ban during summer ozone season for Northern Kentucky; and

• PSD requirements.

In addition to the measures listed above, further reductions will be achieved throughout the implementation of new federal regulations to further control the emission of Hazardous Air Pollutants that are VOC and the emission control programs being imposed as a result of enforcement agreements with some sources in the area. The reductions cannot be quantified at this time, but will be reflected in future triennial assessments.

Regarding point source emissions for the Kentucky portion of the tri-state Cincinnati-Hamilton Area, Duke Power's East Bend plant located in Boone County operates a wet lime scrubber, which controls sulfur dioxide emissions; and a modified furnace designed with low NO_X burners and selective catalytic reduction to reduce NO_X emissions.

Criteria (4)—*The area has a fully approved maintenance plan pursuant to section 175A of the CAA.*

In conjunction with its request to redesignate Northern Kentucky (as part of the tri-state Cincinnati-Hamilton 1997 8-hour ozone nonattainment area) to attainment, Kentucky submitted a SIP revision to provide for the maintenance of the 1997 8-hour ozone NAAQS for at least 10 years after the effective date of redesignation to attainment and commits to submitting a revised 10 year maintenance plan eight years after the redesignation is approved if they are still required to do so at that time.

a. What is required in a maintenance plan?

Section 175A of the CAA sets forth the elements of a maintenance plan for areas seeking redesignation from nonattainment to attainment. Under section 175A, the plan must demonstrate continued attainment of the applicable NAAQS for at least 10 years after the Administrator approves a redesignation to attainment. Eight years after the redesignation, the State of Kentucky must submit a revised maintenance plan, which demonstrates that attainment will continue to be maintained for the 10 years following the initial 10-year period. To address the possibility of future NAAQS violations, the maintenance plan must contain such contingency measures, with a schedule for implementation as EPA deems necessary to assure prompt correction of any future 1997 8-hour ozone violations. Section 175A of the CAA sets forth the requirements for maintenance plans for areas seeking redesignation from nonattainment to attainment. The Calcagni Memorandum provides additional guidance on the content of a maintenance plan. The Calcagni Memorandum explains that an ozone maintenance plan should address five elements: the attainment emissions inventory, maintenance demonstration, monitoring, verification of continued attainment, and a contingency plan. As is discussed more fully below, EPA proposes to find that Kentucky's maintenance plan includes all the necessary components and is approvable as part of the redesignation request.

b. Attainment Emissions Inventory

In coordination with Ohio and Indiana, Kentucky selected 2008 as "the attainment year" for the purposes of demonstrating maintenance of the 1997 8-hour ozone NAAQS. The attainment inventory identifies the level of emissions in the area, which is sufficient to attain the 1997 8-hour ozone standard. Kentucky began development of the attainment inventory by first developing a baseline emissions inventory for Northern Kentucky. The year 2008 was chosen as the base year for developing a comprehensive ozone precursor emissions inventory for which projected emissions could be developed for 2011, 2015, 2018 and 2020. The projected inventory estimates emissions forward to 2020, which meets the 10-year interval required in Section 175A of the CAA. Nonroad mobile emissions were generated using EPA's National Mobile Inventory Model (NMIM), with the following exceptions: recreational motorboat populations and spatial surrogates were updated; emissions estimates were developed for commercial marine vessels, aircraft, and railroads as these three nonroad categories are not included in NMIM. On-road mobile source emissions were calculated using EPA's MOBILE6.2 emission factors model. The 2008 VOC and NO_X emissions, as well as the emissions for other years, for Northern Kentucky were developed consistent with EPA guidance, and are summarized in Tables 3 and 4 in the following subsection.

c. Maintenance Demonstration

The January 29, 2010, redesignation request includes a maintenance plan for Northern Kentucky. The maintenance plan:

(i) Shows maintenance of the 1997 8-hour ozone standard by providing information to support the demonstration that current and future emissions of VOC and NO_X remain at or below attainment year 2008 emissions levels. The year 2008 was chosen as the attainment year because it is one of the years in the most recent three-year period (2007-2009) during which the tri-state Cincinnati-Hamilton Area attained the 1997 8-hour ozone standard. A maintenance demonstration need not be based on modeling. See *Wall* v. *EPA,* 265 F.3d 426 (6th Cir. 2001), *Sierra Club* v. *EPA,* 375 F.3d 537 (7th Cir. 2004). See also 66 FR 53094, 53099–53100 (October 19, 2001), 68 FR 25413, 25430–25432 (May 12, 2003)).

(ii) Uses 2008 as the attainment year and includes future emission inventory projections for 2011, 2015, 2018, and 2020.

(iii) Identifies an "out year," at least 10 years (and beyond) after the time necessary for EPA to review and approve the redesignation request. Per 40 CFR part 93, NO_X and VOC MVEBs were established for the last year (2020) of the maintenance plan. Additionally, Kentucky chose, through interagency consultation, to establish MVEBs for 2015 for NO_X and VOC. See section VII below.

(iv) Provides the following actual and projected emissions inventories, in tons per day (tpd) for Northern Kentucky. See Tables 3 and 4.

* Calculated using MOBILE6.2.

Kentucky is using emissions inventory projections for the years 2011, 2015, 2018 and 2020 to demonstrate maintenance. The Ohio-Kentucky-Indiana (OKI) Regional Council of Governments calculated onroad emissions for 2011, 2015, 2018 and 2020 using the MOBILE6.2 emissions model in addition to using this model to calculate the 2008 base year emissions. Emissions estimates for the remaining source categories were based on future year inventories developed by Kentucky and the Lake Michigan Air Directors Consortium (LADCO). Specifically, for Kentucky's submission, LADCO developed the emissions and projections for area and nonhighway mobile sources. Kentucky used information in the National Emissions Inventory (NEI) database and Kentucky's Emissions Inventory Systems database to determine the point source emissions. A comparison was made between employment projections and earnings projections using the U.S. Department of Commerce's Bureau of Economic Analysis data. Kentucky's submission provides detailed documentation for how the emissions were developed for this submission. EPA has reviewed this information and has determined that the emissions were developed using methodology that is consistent with EPA policy and guidance.

Consideration of CAIR for Maintenance Demonstration. The emission projections show that Ohio, Indiana (75 FR 8882–8884), and Kentucky do not expect emissions in the tri-state Cincinnati-Hamilton Area to exceed the level of the 2008 attainment year inventory during the maintenance period, even without implementation of CAIR (see also discussion below). As shown in Table 5, VOC and NO_X emissions in the entire tri-state Cincinnati-Hamilton Area are projected to decrease by 30.41 tpd and 47.00 tpd, respectively, between 2008 and 2020.

Table 5. Comparison of 2008, 2015 and 2020 VOC and NO_X Emissions for the Entire Tri-State Cincinnati-Hamilton Area (tpd)

	VOC					NOx				
	2008	2015	2020	Net Change (2008-2015)	Net Change (2008-2020)	2008	2015	2020	Net Change (2008-2015)	Net Change (2008-2020)
Point	14.91	17.50	18.46	2.59	3.55	112.29	159.03	163.65	46.74	51.36

To further support the maintenance plan demonstrations for the tri-state Cincinnati-Hamilton Area, LADCO performed a regional modeling analysis to address the effect of the recent court decision vacating CAIR. This analysis is documented in LADCO's "Regional Air Quality Analyses for Ozone, $PM_{2.5}$, and Regional Haze: Final Technical Support Document (Supplement), September 12, 2008;" see the discussion in EPA's proposed approval of the Ohio and Indiana maintenance plans for the tri-state Cincinnati-Hamilton Area. See 75 FR 8883–8884.

LADCO produced a base year inventory for 2005 and future year inventories for 2009, 2012, and 2018. To estimate future electric generating units (EGU) NO_X emissions without implementation of CAIR, LADCO projected 2007 EGU NO_X emissions for all states in the modeling domain based on Energy Information Administration growth rates by state (North American Electric Reliability Corporation region) and fuel type for the years 2009, 2012 and 2018. The assumed 2007–2018 growth rates were 8.8 percent for Illinois, Iowa, Missouri and Wisconsin; 13.5 percent for Indiana, Kentucky, Michigan and Ohio; and 15.1 percent for Minnesota. Emissions were adjusted by applying legally enforceable controls, e.g., consent decree or rule.

Ozone modeling performed by LADCO supports the conclusion that the tri-state Cincinnati-Hamilton Area will maintain the standard throughout the maintenance period. Peak modeled ozone levels in the area for 2009, 2012 and 2018 are 0.082 ppm, 0.081 ppm, and 0.078 ppm, respectively. These projected ozone levels were modeled applying only legally enforceable controls; *e.g.,* consent decrees, rules, the NO_X SIP Call, Federal motor vehicle control programs (FMVCP), etc. Because these programs will remain in place, emission levels, and therefore ozone levels, would not be expected to increase significantly between 2018 and 2020.

EPA has considered the relationship of the maintenance plans to the reductions required pursuant to CAIR. CAIR was remanded to EPA, and the process of developing a replacement rule is ongoing. However, the remand of CAIR does not alter the requirements of the NO_X SIP Call, and Kentucky has demonstrated maintenance without any additional CAIR requirements (beyond those required by the NO_X SIP Call). Therefore, EPA believes that Kentucky's demonstration of maintenance under sections 175A and 107(d)(3)(E) is valid.

The NO_X SIP Call requires states to make significant, specific emissions reductions. It also provided a mechanism, the NO_X Budget Trading Program, which states could use to achieve those reductions. When EPA promulgated CAIR, it discontinued (starting in 2009) the NO_X Budget Trading Program, 40 CFR 51.121(r), but created another mechanism, the CAIR ozone season trading program, which states could use to meet their SIP Call obligations, 70 FR 25289–90. EPA notes that a number of states, when submitting SIP revisions to require sources to participate in the CAIR ozone season trading program, removed the SIP provisions that required sources to participate in the NO_X Budget Trading Program. In addition, because the provisions of CAIR, including the ozone season NO_X trading program, remain in place during the remand, EPA is not currently administering the NO_X Budget Trading Program. Nonetheless, all states, regardless of the current status of

their regulations that previously required participation in the NO_X Budget Trading Program, will remain subject to all of the requirements in the NO_X SIP Call even if the existing CAIR ozone season trading program is withdrawn or altered. In addition, the anti-backsliding provisions of 40 CFR 51.905(f) specifically provide that the provisions of the NO_X SIP Call, including the statewide NO_X emission budgets, continue to apply after revocation of the 1-hour standard.

All NO_X SIP Call states have SIPs that currently satisfy their obligations under the SIP Call, the SIP Call reduction requirements are being met, and EPA will continue to enforce the requirements of the NO_X SIP Call even after any response to the CAIR remand. For these reasons, EPA believes that regardless of the status of the CAIR program, the NO_X SIP Call requirements can be relied upon in demonstrating maintenance. Here, Kentucky has demonstrated maintenance based in part on those requirements.

d. Monitoring Network

There are currently eleven monitors measuring ozone in the tri-state Cincinnati-Hamilton Area (three in Northern Kentucky and one in the remainder in the Ohio portion of this Area). Kentucky has committed, in the maintenance plan, to continue operation of the three monitors in Northern Kentucky in compliance with 40 CFR part 58, and has addressed the requirement for monitoring. Ohio has made a similar commitment in their redesignation and maintenance plan submission to EPA for this Area. There is no monitor in the Indiana portion of this Area.

e. Verification of Continued Attainment

The Commonwealth of Kentucky has the legal authority to enforce and implement the requirements of the ozone maintenance plan. This includes the authority to adopt, implement and enforce any subsequent emissions control contingency measures determined to be necessary to correct future ozone attainment problems.

Kentucky will track the progress of the maintenance plan by performing future reviews of emissions inventory for Northern Kentucky using the latest emissions factors, models and methodologies. For these periodic inventories, Kentucky will review the assumptions made for the purpose of the maintenance demonstration concerning projected growth of activity levels. If any of these assumptions appear to have changed substantially, Kentucky commits to re-project emissions.

f. Contingency Plan

The contingency plan provisions are designed to promptly correct a violation of the NAAQS that occurs after redesignation. Section 175A of the CAA requires that a maintenance plan include such contingency measures as EPA deems necessary to assure that the state will promptly correct a violation of the NAAQS that occurs after redesignation. The maintenance plan should identify the contingency measures to be adopted, a schedule and procedure for adoption and implementation, and a time limit for action by the state. A state should also identify specific indicators to be used to determine when the contingency measures need to be implemented. The maintenance plan must include a requirement that a state will implement all measures with respect to control of the pollutant that were contained in the SIP before redesignation of the area to attainment in accordance with section 175A(d).

In the January 29, 2010, submittal, Kentucky affirms that all programs instituted by the Commonwealth and EPA will remain enforceable, and that sources are prohibited from reducing emissions controls following the redesignation of the area. Kentucky commits in their submission to provide an update for the maintenance plan 8 years after formal redesignation in accordance with section 175A(b) of the CAA should this requirement remain applicable for this Area.

As required by section 175A of the CAA, Kentucky has adopted a contingency plan to address possible future 8-hour ozone air quality problems. In the event that a measured value of the fourth highest maximum is 0.085 ppm or greater in any portion of the maintenance area in a single ozone season, or if periodic emissions inventory updates reveal excessive or unanticipated growth greater than ten percent in ozone precursor emissions, the Commonwealth will evaluate existing control measures to see if any further emission reductions should be implemented at that time.

In the event of a monitored violation of the 1997 8-hour ozone NAAQS in the tri-state Cincinnati-Hamilton Area, Kentucky commits to adopt, within nine months, one or more of the following contingency measures to re-attain the standard. A violation of the standard occurs when the 3-year average of the annual fourth-highest daily maximum 8-hour average ozone concentration is equal to or greater than 0.085 ppm. All regulatory programs will be adopted and implemented within 18 months after the triggering monitored violation.

- Implementation of a program to require additional emissions reductions on stationary sources;
- Implementation of fuel programs, including incentives for alternative fuels; Restriction of certain roads or lanes to, or construction of such roads or lands for use by passenger buses or high-occupancy vehicles;
- Trip-reduction ordinances;
- Employer-based transportation management plans, including incentives;
- Programs to limit or restrict vehicle us in downtown areas, or other areas of emissions concentration, particularly during periods of peak use;
- Programs for new construction and major reconstructions of paths or tracks for use by pedestrians or by non-motorized vehicles when economically feasible and in the public interest.

Kentucky also reserves the right in its submission to implement other contingency measures if new control programs should be developed and advantageous for the Area.

EPA believes that that the maintenance plan adequately addresses the five basic components of a maintenance plan: attainment inventory, maintenance demonstration, monitoring network, verification of continued attainment, and a contingency plan. Thus EPA proposes to find that the maintenance plan SIP revision submitted by the Commonwealth of Kentucky for Northern Kentucky meets the requirements of section 175A of the CAA and is approvable.

VII. What is EPA's analysis of Kentucky's proposed state NO_X and VOC MVEBs for Northern Kentucky?

Under the CAA, states are required to submit, at various times, control strategy SIPs and maintenance plans in ozone areas. These control strategy SIPs (RFP and attainment demonstration) and maintenance plans establish MVEBs for criteria pollutants and/or their precursors to address pollution from cars and trucks. Per 40 CFR part 93, an MVEB is established for the last year of the maintenance plan. A state may adopt MVEBs for other years as well. The MVEB is the portion of the total allowable emissions in the maintenance demonstration that is allocated to highway and transit vehicle use and emissions. See 40 CFR 93.101. The MVEB serves as a ceiling on emissions from an area's planned transportation system. The MVEB concept is further

explained in the preamble to the November 24, 1993, transportation conformity rule (58 FR 62188). The preamble also describes how to establish the MVEB in the SIP and how to revise the MVEB.

After interagency consultation with the transportation partners for the tri-state Cincinnati-Hamilton Area, Kentucky has elected to develop MVEBs for VOC and NO_X for Northern Kentucky separate from the remainder of the tri-state Cincinnati-Hamilton Area. MVEBs for the remainder of the tri-state Cincinnati-Hamilton Area is addressed in the Ohio and Indiana submittals. Kentucky is developing these MVEBs for Northern Kentucky, as required, for the last year of its maintenance plan, 2020, an interim year, 2015. The MVEBs for 2015 and 2020 reflect the total on-road emissions for those individual years, plus an allocation from the available NO_X and VOC safety margin for each year. Under 40 CFR 93.101, the term safety margin is the difference between the attainment level (from all sources) and the projected level of emissions (from all sources) in the maintenance plan. The safety margin can be allocated to the transportation sector; however, the total emissions must remain below the attainment level. These MVEBs and allocation from the safety margin were developed in consultation with the transportation partners and were added to account for uncertainties in population growth, changes in model VMT and new emission factor models. For 2015, the safety margin added to the mobile VOC emissions 2 tpd, and the safety margin added to the mobile NO_X emissions is 3 tpd. For 2020, the safety margin added to the mobile VOC emissions is 3 tpd, and the safety margin added to the mobile NO_X emissions is 5 tpd. The resulting NO_X and VOC MVEBs for Northern Kentucky are defined in Table 6 below.

TABLE 6—NORTHERN KENTUCKY 1997 8-HOUR OZONE NO_X AND VOC MVEBS

[Summer season tons per day]

	2015	2020
NO_X	14.40	13.27
VOC	9.76	10.07

As mentioned above, Kentucky has chosen to allocate a portion of the available safety margin to the 2015 and 2020 NO_X and VOC MVEBs. The following tables identify the original NO_X and VOC safety margins that were available in the tri-state Cincinnati Area for the applicable years. It should be noted that the safety margin allocation from above is not reflected in the following table so any further allocation of the available safety margin in the Kentucky portion of this area will be quantified at the time of the allocation should the Commonwealth elect to allocate additional safety margin to the MVEBs in the Northern Kentucky Area. Table 7 and Table 8 below detail the available safety margin for the tri-state Cincinnati-Hamilton Area prior to allocations provided for MVEBs for Northern Kentucky and the remainder of the tri-state Area. Kentucky's has remaining safety margin to allocate. Should Kentucky decide to allocate further safety margin to the MVEB, the Commonwealth will do so through a subsequent SIP revision which will identify the available safety margin for allocation and any additional allocation.

Combined Total	309.47	280.15	262.47	30.24	46.95

Through this rulemaking, EPA is proposing to approve the 2015 and 2020 MVEBs for VOC and NO_X for Northern Kentucky because EPA has determined that the Area maintains the 1997 8-hour ozone NAAQS with the emissions at the levels of the budgets. Once the MVEBs for Northern Kentucky (the subject of this rulemaking) are approved or found adequate (whichever is done first), they must be used for future conformity determinations. See section VIII for more information on the status of EPA's adequacy determination for the proposed NO_X and VOC MVEBs for the years 2015 and 2020 for Northern Kentucky.

VIII. What is the status of EPA's adequacy determination for the proposed NO_X and VOC MVEBs for the years 2015 and 2020 for Northern Kentucky?

Under section 176(c) of the CAA, new transportation projects, such as the construction of new highways, must "conform" to (*i.e.,* be consistent with) the part of the state's air quality plan that addresses pollution from cars and trucks. "Conformity" to the SIP means that transportation activities will not cause new air quality violations, worsen existing violations, or delay timely attainment of the NAAQS. If a transportation plan does not "conform," most new projects that would expand the capacity of roadways cannot go forward. Regulations at 40 CFR part 93 set forth EPA policy, criteria, and procedures for demonstrating and assuring conformity of such transportation activities to a SIP. The regional emissions analysis is one, but not the only, requirement for implementing transportation conformity. Transportation conformity is a requirement for nonattainment and maintenance areas. Maintenance areas are areas that were previously nonattainment for a particular NAAQS but have since been redesignated to attainment with a maintenance plan for that NAAQS.

When reviewing submitted "control strategy" SIPs or maintenance plans containing MVEBs, EPA may affirmatively find the MVEB contained therein "adequate" for use in determining transportation conformity. Once EPA affirmatively finds the submitted MVEB is adequate for transportation conformity purposes, that MVEB must be used by state and Federal agencies in determining whether proposed transportation projects "conform" to the SIP as required by section 176(c) of the CAA.

EPA's substantive criteria for determining "adequacy" of an MVEB are set out in 40 CFR 93.118(e)(4). The process for determining "adequacy" consists of three basic steps: Public notification of a SIP submission, a public comment period, and EPA's adequacy finding. This process for determining the adequacy of submitted SIP MVEBs was initially outlined in EPA's May 14, 1999, guidance, "Conformity Guidance on Implementation of March 2, 1999, Conformity Court Decision." This guidance was finalized in the Transportation Conformity Rule Amendments for the "New 8-Hour Ozone and $PM_{2.5}$ National Ambient Air Quality Standards and Miscellaneous Revisions for Existing Areas; transportation conformity rule amendments—Response to Court Decision and Additional Rule Change," on July 1, 2004 (69 FR 40004). Additional information on the adequacy process for MVEBs is available in the proposed rule entitled, "Transportation Conformity Rule Amendments: Response to Court Decision and Additional Rule Changes," 68 FR 38974, 38984 (June 30, 2003).

As discussed earlier, Kentucky's maintenance plan submission includes VOC and NO_X state MVEBs for Northern Kentucky for the years 2015 and 2020. EPA reviewed both the VOCs and NO_X state MVEBs through the adequacy process. The Kentucky SIP submission, including the Northern Kentucky VOC and NO_X MVEBs was open for public comment on EPA's adequacy website on February 3, 2010, found at: *http://www.epa.gov/otaq/stateresources/transconf/currsips.htm.* The EPA public comment period on adequacy of the 2015 and 2020 VOC and NO_X state MVEBs for Northern Kentucky closed on March 5, 2010. EPA did not receive any comments on the adequacy of the MVEBs, nor did EPA receive any requests for the SIP submittal. EPA provided a separate adequacy posting for the MVEBs in association with the Ohio and Indiana portions of this Area. The status of the adequacy process for the Ohio and Indiana MVEBs is discussed in EPA's separate action related to those areas (*see* 75 FR 8871, 8886; February 26, 2010).

EPA intends to make its determination on the adequacy of the 2015 and 2020 MVEBs for Northern Kentucky for transportation conformity purposes by completing the adequacy process that was started on February 3, 2010, in coordination with the final rule for this redesignation request and maintenance plan. After EPA finds the 2015 and 2020 MVEBs, adequate or approves them, the new MVEBs for VOC and NO_X must be used, for future transportation conformity determinations. For required regional emissions analysis years that involve the years 2015 through 2019, the applicable budgets for the purposes of conducting transportation conformity will be the new 2015 MVEBs. For required regional emissions analysis years that involve 2020 or beyond, the applicable budgets will be the new 2020 MVEBs for Northern Kentucky. The 2015 and 2020 MVEBs are defined in section VII of this proposed rulemaking.

IX. What is EPA's analysis of the proposed 2008 base year emissions inventory for Northern Kentucky?

As discussed above, section 172(c)(3) of the CAA requires areas to submit a base year emissions inventory. As part of Kentucky's request to redesignate the

Kentucky portion of the tri-state Cincinnati-Hamilton Area, the Commonwealth submitted 2008 base year emissions inventory to meet this requirement. Emissions contained in the submittal cover the general source categories of point sources, area sources, on-road mobile sources, and non-road mobile sources. All emission summaries were accompanied by source-specific descriptions of emission calculation procedures and sources of input data. On-road mobile emissions were prepared by the OKI using the MOBILE6.2 emissions model.

Kentucky's submittal documents 2008 emissions in the Kentucky portion of the tri-state Cincinnati-Hamilton Area in units of tons per summer day. Table 9 below provides a summary of the 2008 summer day emissions of VOC and NO_X for Northern Kentucky.

NORTHERN KENTUCKY 2008 SUMMER DAY EMISSIONS FOR VOC AND NO_X

[Tons per day]

	NO_X	VOC
Boone	23.27	2.81
Campbell	0.02	0.28
Kenton	0.04	1.17
Point Total	23.33	4.79
Boone	5.02	8.41
Campbell	1.32	4.34
Kenton	4.06	7.88
Area Total	10.40	20.63
Boone	11.02	5.07
Campbell	5.34	1.51
Kenton	7.33	1.95
Nonroad Total	23.69	8.53
Boone	8.53	4.00
Campbell	4.88	2.29
Kenton	8.37	3.85
Mobile Total	21.78	10.14
Northern Kentucky Total	79.20	44.09

EPA is proposing to approve this 2008 base year inventory as meeting the section 172(c)(3) emissions inventory requirement.

X. What are EPA's proposed actions?

EPA is proposing to: (1) To determine that the tri-state Cincinnati-Hamilton Area has attained the 1997 8-hour ozone NAAQS based on quality assured monitoring data from 2007–2009; (2) approve Kentucky's redesignation request for Boone, Campbell and Kenton Counties in Kentucky as part of the tri-state Cincinnati Area; (3) approve Kentucky's January 29, 2010 SIP revision providing the 1997 8-hour ozone maintenance plan for Northern Kentucky, including the MVEBs for NO_X and VOC for the years 2015 and 2020; and (4) approve the 2008 emissions inventory for Northern Kentucky as meeting the requirements of the CAA.

EPA's proposed approval is based on the Commonwealth's demonstration that the plan meets the requirements of section 175A of the CAA. After evaluating the Commonwealth's redesignation request, EPA believes that, upon final approval of the emissions inventory that was also submitted, the request meets the redesignation criteria set forth in CAA sections 107(d)(3)(E) and 175A. Therefore, EPA is proposing to approve the redesignation of the Kentucky portion of the tri-state Cincinnati-Hamilton Area from nonattainment to attainment for the 1997 8-hour ozone NAAQS. The final approval of this redesignation request would change the official designation for the Kentucky portion of the tri-state Cincinnati-Hamilton Area from nonattainment to attainment for the 1997 8-hour ozone NAAQS. Final approval would also establish 2015 and 2020 NO_X and VOC MVEBs for Northern Kentucky to use for the purposed of implementing transportation conformity. EPA is proposing to approve Kentucky's 2008 base year emissions inventory for the Kentucky portion of the tri-state Cincinnati-Hamilton Area as meeting the requirements of section 172(c)(3) EPA is taking action on the redesignation requests, emission inventories and maintenance plans for the Ohio and Indiana portions (as a part of the tri-state Cincinnati-Hamilton Area) in a separate but coordinated action.

In this action, EPA is also describing the status of EPA's adequacy determination for the new 2015 and 2020 MVEBs that are contained in the 1997 8-hour ozone maintenance plan for Northern Kentucky in accordance with 40 CFR 93.118(f)(1). Within 24 months from the effective date of EPA's adequacy finding for the MVEBs, or the effective date for the final rule for this action, whichever is earlier, the transportation partners will need to demonstrate conformity to the new NO_X and VOC MVEBs pursuant to 40 CFR 93.104(e). EPA intents to conclude it adequacy process for the Northern Kentucky MVEBs with its final rulemaking for this proposed action. MVEBs for the Ohio and Indiana portions of this Area are included in the Ohio and Indiana submittals, and are being addressed through EPA's separate action for those submissions.

XI. Statutory and Executive Order Reviews

Under the CAA, redesignation of an area to attainment and the accompanying approval of a maintenance plan under section 107(d)(3)(E) are actions that affect the status of a geographical area and do not impose any additional regulatory requirements on sources beyond those imposed by state law. A redesignation to attainment does not in and of itself

create any new requirements, but rather results in the applicability of requirements contained in the CAA for areas that have been redesignated to attainment. Moreover, under the CAA, the Administrator is required to approve a SIP submission that complies with the provisions of the Act and applicable Federal regulations. 42 U.S.C. 7410(k); 40 CFR 52.02(a). Thus, in reviewing SIP submissions, EPA's role is to approve state choices, provided that they meet the criteria of the CAA. Accordingly, these proposed actions merely approve state law as meeting Federal requirements and does not impose additional requirements beyond those imposed by state law. For these reasons, these proposed actions:

- Are not a "significant regulatory action" subject to review by the Office of Management and Budget under Executive Order 12866 (58 FR 51735, October 4, 1993);
- Do not impose an information collection burden under the provisions of the Paperwork Reduction Act (44 U.S.C. 3501 *et seq.*);
- Are certified as not having a significant economic impact on a substantial number of small entities under the Regulatory Flexibility Act (5 U.S.C. 601 *et seq.*);
- Do not contain any unfunded mandate or significantly or uniquely affect small governments, as described in the Unfunded Mandates Reform Act of 1995 (Pub. L. 104–4);
- Do not have Federalism implications as specified in Executive Order 13132 (64 FR 43255, August 10, 1999);
- Are not an economically significant regulatory action based on health or safety risks subject to Executive Order 13045 (62 FR 19885, April 23, 1997);
- Are not a significant regulatory action subject to Executive Order 13211 (66 FR 28355, May 22, 2001);
- Are not subject to requirements of Section 12(d) of the National Technology Transfer and Advancement Act of 1995 (15 U.S.C. 272 note) because application of those requirements would be inconsistent with the CAA; and
- Do not provide EPA with the discretionary authority to address, as appropriate, disproportionate human health or environmental effects, using practicable and legally permissible methods, under Executive Order 12898 (59 FR 7629, February 16, 1994).

In addition, this rule does not have tribal implications as specified by Executive Order 13175 (65 FR 67249, November 9, 2000), because the SIP is not approved to apply in Indian country located in the state, and EPA notes that it will not impose substantial direct costs on tribal governments or preempt tribal law.

47 CFR Part 64

[CG Docket No. 03–123; DA 10–761]

Telecommunications Relay Services and Speech-to-Speech Services for Individuals With Hearing and Speech Disabilities

AGENCY: Federal Communications Commission.

ACTION: Proposed rule.

SUMMARY: In this document, the Commission, via the Consumer and Governmental Affairs Bureau (Bureau), seeks comment on the annual payment formulas and funding requirement estimates for the Interstate Telecommunications Relay Services (TRS) Fund (Fund) for the period of July 1, 2010, through June 30, 2011 (2010–2011 Fund year), as proposed by the National Exchange Carrier Association (NECA), the Fund Administrator. The Bureau seeks comment on NECA's proposed compensation rates for Interstate TRS, Speech-to-Speech Services (STS), Captioned Telephone Services (CTS), Internet Protocol (IP) CTS, IP Relay, and Video Relay Services (VRS), for the 2010–2011 Fund year, as well as on NECA's proposals for the carrier contribution factor and funding requirement.

DATES: Comments are due on or before May 14, 2010; reply comments are due on or before May 21, 2010.

ADDRESSES: You may submit comments, identified by CG Docket No. 03–123, by any of the following methods:

- *Federal eRulemaking Portal: http://www.regulations.gov*. Follow the instructions for submitting comments.
- *Federal Communications Commission's Web Site: http://fjallfoss.fcc.gov/ecfs2/*. Follow the instructions for submitting comments.
- *People with Disabilities:* Contact the FCC to request reasonable accommodations (accessible format documents, sign language interpreters, CART, etc.) by e-mail: *FCC504@fcc.gov* or phone: 202–418–0530 or TTY: 202–418–0432.

For detailed instructions for submitting comments and additional information on the rulemaking process, *see* the **SUPPLEMENTARY INFORMATION** section of this document.

ENVIRONMENTAL PROTECTION AGENCY

40 CFR Parts 51, 52, 72, 78, and 97

[EPA–HQ–OAR–2009–0491; FRL–9174–9]

RIN 2060–AP50

Federal Implementation Plans To Reduce Interstate Transport of Fine Particulate Matter and Ozone

AGENCY: Environmental Protection Agency (EPA).

ACTION: Proposed rule.

SUMMARY: EPA is proposing to limit the interstate transport of emissions of nitrogen oxides (NO_X) and sulfur dioxide (SO_2). In this action, EPA is proposing to both identify and limit emissions within 32 states in the eastern United States that affect the ability of downwind states to attain and maintain compliance with the 1997 and 2006 fine particulate matter ($PM_{2.5}$) national ambient air quality standards (NAAQS) and the 1997 ozone NAAQS. EPA is proposing to limit these emissions through Federal Implementation Plans (FIPs) that regulate electric generating units (EGUs) in the 32 states. This action will substantially reduce the impact of transported emissions on downwind states. In conjunction with other federal and state actions, it helps assure that all but a handful of areas in the eastern part of the country will be in compliance with the current ozone and $PM_{2.5}$ NAAQS by 2014 or earlier. To the extent the proposed FIPs do not fully address all significant transport, EPA is committed to assuring that any additional reductions needed are addressed quickly. EPA takes comments on ways this proposal could achieve additional NO_X reductions and additional actions including other rulemakings that EPA could undertake to achieve any additional reductions needed.

DATES: *Comments.* Comments must be received on or before October 1, 2010.

Public Hearing: Three public hearings will be held before the end of the comment period. The dates, times and locations will be announced separately. Please refer to **SUPPLEMENTARY INFORMATION** for additional information on the comment period and the public hearings.

ADDRESSES: Submit your comments, identified by Docket ID No. EPA–HQ–OAR–2009–0491 by one of the following methods:

- *Fax:* (202) 566–9744. Attention Docket ID No. EPA–HQ–OAR–2009–0491.
- *Mail:* EPA Docket Center, EPA West (Air Docket), Attention Docket ID No. EPA–HQ–OAR–2009–0491, U.S. Environmental Protection Agency, Mailcode: 2822T, 1200 Pennsylvania Avenue, NW., Washington, DC 20460. Please include 2 copies. In addition, please mail a copy of your comments on the information collection provisions to the Office of Information and Regulatory Affairs, Office of Management and Budget (OMB), Attn: Desk Officer for EPA, 725 17th Street, NW., Washington, DC 20503.
- *Hand Delivery:* U.S. Environmental Protection Agency, EPA West (Air Docket), 1301 Constitution Avenue, Northwest, Room 3334, Washington, DC 20004, Attention Docket ID No. EPA–HQ–OAR–2009–0491. Such deliveries are only accepted during the Docket's normal hours of operation, and special arrangements should be made for deliveries of boxed information.

Instructions. Direct your comments to Docket ID No. EPA–HQ–OAR–2009–0491. EPA's policy is that all comments received will be included in the public docket without change and may be made available online at *http://www.regulations.gov*, including any personal information provided, unless the comment includes information claimed to be Confidential Business Information (CBI) or other information whose disclosure is restricted by statute. Do not submit information that you consider to be CBI or otherwise protected through *http://www.regulations.gov* or e-mail. The *http://www.regulations.gov* Web site is an "anonymous access" system, which means EPA will not know your identity or contact information unless you provide it in the body of your comment. If you send an e-mail comment directly to EPA without going through *http://www.regulations.gov*, your e-mail address will be automatically captured and included as part of the comment that is placed in the public docket and made available on the Internet. If you submit an electronic comment, EPA recommends that you include your name and other contact information in the body of your comment and with any disk or CD–ROM you submit. If EPA cannot read your comment due to technical difficulties and cannot contact you for clarification, EPA may not be able to consider your comment. Electronic files should avoid the use of special characters, avoid any form of encryption, and be free of any defects or viruses. For additional information about EPA's public docket, visit the EPA Docket Center homepage at *http://www.epa.gov/epahome/dockets.htm.*

Docket. All documents in the docket are listed in the *http://www.regulations.gov* index. Although listed in the index, some information is not publicly available, *e.g.*, CBI or other information whose disclosure is restricted by statute. Certain other material, such as copyrighted material, will be publicly available only in hard copy. Publicly available docket materials are available either electronically in *http://www.regulations.gov* or in hard copy at the Air and Radiation Docket and Information Center, EPA/DC, EPA West Building, Room 3334, 1301 Constitution Ave., NW., Washington, DC. The Public Reading Room is open from 8:30 a.m. to 4:30 p.m., Monday through Friday, excluding legal holidays. The telephone number for the Public Reading Room is (202) 566–1744, and the telephone number for the Air Docket is (202) 566–1742.

FOR FURTHER INFORMATION CONTACT: Mr. Tim Smith, Air Quality Policy Division, Office of Air Quality Planning and Standards (C539–04), Environmental Protection Agency, Research Triangle Park, NC 27711; telephone number: (919) 541–4718; fax number: (919) 541–0824; e-mail address: *smith.tim@epa.gov.* For legal questions, please contact Ms. Sonja Rodman, U.S. EPA, Office of General Counsel, Mail Code 2344A, 1200 Pennsylvania Avenue, NW., Washington, DC 20460, telephone (202) 564–4079; e-mail address *rodman.sonja@epa.gov.*

II. General Information

A. Does this action apply to me?

This rule affects EGUs, and regulates the following groups:

Industry group	NAICS [a]
Utilities (electric, natural gas, other systems).	2211, 2212, 2213

[a] North American Industry Classification System.

This table is not intended to be exhaustive, but rather provides a guide for readers regarding entities likely to be regulated by this action. This table lists the types of entities that EPA is aware of that could potentially be regulated. Other types of entities not listed in the table could also be regulated. To determine whether your facility would be regulated by the proposed rule, you should carefully examine the applicability criteria in proposed §§ 97.404, 97.504, 97,604, and 97.704.

B. Where can I get a copy of this document and other related information?

In addition to being available in the docket, an electronic copy of this proposal will also be available on the World Wide Web. Following signature by the EPA Administrator, a copy of this action will be posted on the transport rule Web site *http://www.epa.gov/airtransport*.

C. What should I consider as I prepare my comments for EPA?

1. *Submitting CBI.* Do not submit this information to EPA through *http://www.regulations.gov* or e-mail. Clearly mark the part or all of the information that you claim to be CBI. For CBI information in a disk or CD–ROM that you mail to EPA, mark the outside of the disk or CD–ROM as CBI and then identify electronically within the disk or CD–ROM the specific information that is claimed as CBI. In addition to one complete version of the comment that includes information claimed as CBI, a copy of the comment that does not contain the information claimed as CBI must be submitted for inclusion in the public docket. Information so marked will not be disclosed except in accordance with procedures set forth in 40 CFR part 2. Send or deliver information identified as CBI only to the following address: Roberto Morales, OAQPS Document Control Officer (C404–02), U.S. EPA, Research Triangle Park, NC 27711, Attention Docket ID No. EPA–HQ–OAR–2009–0491.

2. *Tips for preparing your comments.* When submitting comments, remember to:

- Identify the rulemaking by docket number and other identifying information (subject heading, **Federal Register** date and page number).
- Follow directions—The agency may ask you to respond to specific questions or organize comments by referencing a Code of Federal Regulations (CFR) part or section number.
- Explain why you agree or disagree; suggest alternatives and substitute language for your requested changes.
- Describe any assumptions and provide any technical information and/or data that you used.
- If you estimate potential costs or burdens, explain how you arrived at your estimate in sufficient detail to allow for it to be reproduced.
- Provide specific examples to illustrate your concerns, and suggest alternatives.
- Explain your views as clearly as possible, avoiding the use of profanity or personal threats.
- Make sure to submit your comments by the comment period deadline identified.

D. How can I find information about the public hearings?

The EPA will hold three public hearings on this proposal. The dates, times and locations of the pubic hearings will be announced separately. Oral testimony will be limited to 5 minutes per commenter. The EPA encourages commenters to provide written versions of their oral testimonies either electronically or in paper copy. Verbatim transcripts and written statements will be included in the rulemaking docket. If you would like to present oral testimony at one of the hearings, please notify Ms. Pamela S. Long, Air Quality Policy Division (C504–03), U.S. EPA, Research Triangle Park, NC 27711, telephone number (919) 541–0641; e-mail: *long.pam@epa.gov*. Persons interested in presenting oral testimony should notify Ms. Long at least 2 days in advance of the public hearings. For updates and additional information on the public hearings, please check EPA's website for this rulemaking, *http://www.epa.gov/airtransport*. The public hearings will provide interested parties the opportunity to present data, views, or arguments concerning the proposed rule. The EPA officials may ask clarifying questions during the oral presentations, but will not respond to the presentations or comments at that time. Written statements and supporting information submitted during the comment period will be considered with the same weight as any oral comments and supporting information presented at the public hearings.

E. How is this Preamble Organized?

III. Summary of Proposed Rule and Background

A. Summary of Proposed Rule

CAA section 110(a)(2)(D)(i)(I) requires states to prohibit emissions that contribute significantly to nonattainment in, or interfere with maintenance by, any other state with respect to any primary or secondary NAAQS. In this notice, EPA proposes to find that emissions of SO_2 and NO_X in 32 eastern states contribute significantly to nonattainment or interfere with maintenance in one or more downwind states with respect to one or more of three air quality standards—the annual average $PM_{2.5}$ NAAQS promulgated in 1997, the 24-hour average $PM_{2.5}$ NAAQS promulgated in 2006, and the ozone NAAQS promulgated in 1997.[1] These emissions are transported downwind either as SO_2 and NO_X or, after transformation in the atmosphere, as fine particles or ozone. This notice identifies emission reduction responsibilities of upwind states, and also proposes enforceable FIPs to achieve the required emissions reductions in each state through cost-effective and flexible requirements for power plants. Each state will have the option of replacing these Federal rules with state rules to achieve the required amount of emissions reductions from sources selected by the state.

With respect to the annual average $PM_{2.5}$ NAAQS, this proposal finds that 24 eastern states have SO_2 and NO_X emission reduction responsibilities, and quantifies each state's full emission reduction responsibility under section 110(a)(2)(D)(i)(I). With respect to the 24-hour average $PM_{2.5}$ NAAQS, this proposal finds that 25 eastern states have emission reduction responsibilities. The proposed reductions will at least partly eliminate, and subject to further analysis may fully eliminate, these states' significant contribution and interference with maintenance for purposes of the 24-hour average $PM_{2.5}$ standard. In all, emissions reductions related to interstate transport

[1] In the context of the jurisdictions covered by this proposed rule, EPA uses the term "states" to include the District of Columbia.

of fine particles would be required in 28 states.

With respect to the 1997 ozone NAAQS, this proposal requires emissions reductions in 26 states. For 16 of these states, we propose that the required reductions represent their full significant contribution and interference with maintenance for the ozone NAAQS. For an additional 10 states, the required NO_X reductions are needed for these states to make measurable progress towards eliminating their significant contribution and interference with maintenance. EPA has begun to conduct additional information gathering and analysis to determine the extent to which further reductions from these states may be needed to fully eliminate significant contribution and interference with maintenance with the 1997 ozone NAAQS.

This proposed rule would achieve substantial near-term emissions reductions from the power sector. EPA projects that with the proposed rule, EGU SO_2 emissions would be 5.0 million tons lower, annual NO_X emissions would be 700,000 tons lower, and ozone season NO_X emissions would be 100,000 tons lower in 2012, compared to baseline 2012 projections in the proposed covered states. Further, EGU SO_2 emissions would be 4.6 million tons lower, annual NO_X emissions would be 700,000 tons lower, and ozone season NO_X emissions would be 100,000 tons lower in 2014, compared to baseline 2014 projections (which will have dropped from 2012 due to other federal and state requirements, thereby lowering the 2014 baseline). *See* Table III.A–2 for projected EGU emissions with the proposed rule compared to baseline, and Table III.A–3 for projected EGU emissions with the proposed rule compared to 2005 actual emissions. The reductions obtained through the Transport Rule FIPs will help all but a very few areas in the eastern part of the country come into attainment with the 1997 $PM_{2.5}$ and ozone standards and take major strides toward helping states address nonattainment with the 2006 24-hour average $PM_{2.5}$ standard. *See* Table III.A–1 for proposed list of covered states.

EPA is committed to fulfilling its responsibility to ensure that downwind states receive the relief from upwind emissions guaranteed under CAA section 110(a)(2)(D) For the 24-hour $PM_{2.5}$ standard, EPA's air quality modeling shows that in the areas with continuing non-attainment or maintenance problems, the remaining exceedances occur almost entirely in the winter months. The relative importance of particle species such as sulfate and nitrate, is quite different between summer and winter. EPA is moving ahead before the final rule is published to determine the extent to which this wintertime problem is caused by emissions transported from upwind states. Further study of the 24-hour $PM_{2.5}$ results could lead to a number of possible outcomes; EPA cannot judge the relative likelihood of these outcomes at this time. To the extent possible, EPA plans to finalize this rule with a full determination of, and remedy for, significant contribution and interference with maintenance for the 24-hour $PM_{2.5}$ standard. To that end, EPA is expeditiously proceeding with examination of the residual wintertime problem. (See full discussion in section IV.D.)

In the case of ozone, EPA must determine whether further NO_X reductions are warranted in certain upwind states that affect two or three areas with relatively persistent ozone air quality problems. To support a full significant contribution determination for these states, EPA is expeditiously conducting further analysis of NO_X control costs, emissions reductions, air quality impacts, and the nature of the residual air quality issues. EPA's current information indicates that considering NO_X reductions beyond the cost per ton levels proposed in this rule will require analysis of reductions from source categories other than EGUs, as well as from EGUs. EPA believes that developing supplemental information to consider NO_X sources beyond EGUs would substantially delay publication of a final rule beyond the anticipated publication of spring 2011. EPA does not believe that this effort should delay the reductions and large health benefits associated with this proposed rule. Thus, EPA intends to proceed with additional rulemaking to address fully the residual significant contribution to nonattainment and interference with maintenance with the ozone standard as quickly as possible. (See full discussion in section IV.D.)

This proposed rule is the first of several EPA rules to be issued over the next 2 years that will yield substantial health and environmental benefits for the public through regulation of power plants. Fossil-fuel-fired power plants contribute a large and substantial fraction of the emissions of several key air pollutants, and the agency has statutory or judicial obligations to make several regulatory determinations on power plant emissions. The Administrator in January established improved air quality as an Agency priority and announced plans to promote a cleaner and more efficient power sector and have strong but achievable reduction goals for SO_2, NO_X, mercury, and other air toxics."

In addition to this rule, other anticipated actions include a section 112(d) rule for electric utilities to be proposed by March 2011, potential rules to address pollution transport under revised NAAQS, revisions to new source performance standards for coal and oil-fired utility electric generating units, and best available retrofit technology (BART) and regional haze program requirements to protect visibility. These actions, and their relationship to this rule, are discussed further in section III.E.

Ongoing reviews of the ozone and $PM_{2.5}$ NAAQS could result in revised NAAQS. To address any new NAAQS, EPA would propose interstate transport determinations in future notices. Such proposals could require greater emissions reductions from states covered by this proposal and/or require reductions from states not covered by this proposal. In addition, while this action proposes to require reductions from the power sector only, it is possible that reductions from other source categories could be needed to address interstate transport requirements related to any new NAAQS.

With this proposal, EPA is also responding to the remand of the CAIR by the Court in 2008. CAIR, promulgated May 12, 2005 (70 FR 25162) requires 28 states and the District of Columbia to adopt and submit revisions to their State Implementation Plans (SIPs) to eliminate SO_2 and NO_X emissions that contribute significantly to downwind nonattainment of the $PM_{2.5}$ and ozone NAAQS promulgated in July 1997. The CAIR FIPs, promulgated April 26, 2006 (71 FR 25328), regulate EGUs in the covered states and achieve the emissions reductions requirements established by CAIR until states have approved SIPs to achieve the reductions. In July 2008, the DC Circuit Court found CAIR and the CAIR FIPs unlawful. *North Carolina* v. *EPA*, 531 F.3d 896 (DC Cir. 2008). The Court's original decision vacated CAIR. *Id.* at 929–30. However, the Court subsequently remanded CAIR to EPA without vacatur because it found that "allowing CAIR to remain in effect until it is replaced by a rule consistent with our opinion would at least temporarily preserve the environmental values covered by CAIR." *North Carolina* v. *EPA*, 550 F.3d 1176, 1178 (DC Cir. 2008). The CAIR requirements are correctly in place and the CAIR's regional control programs are operating

while EPA develops replacement rules in response to the remand.

As described more fully in the remainder of this preamble, the approaches used in this proposed rule to measure and address each state's significant contribution to downwind nonattainment and interference with maintenance are guided by and consistent with the Court's opinion in *North Carolina* v. *EPA* and address the flaws in CAIR identified by the Court therein. Among other things, the proposal relies on detailed, bottom-up scientific and technical analyses, introduces a state-specific methodology for identifying significant contribution to nonattainment and interference with maintenance, and proposes remedy options to ensure that all necessary reductions are achieved in the covered states.

In this action, EPA proposes to both identify and address emissions within states in the eastern United States that significantly contribute to nonattainment or interfere with maintenance by other downwind states. As discussed in sections III and VII in this preamble and described in greater detail in two separate **Federal Register** notices published on April 25, 2005 (70 FR 21147) and June 9, 2010 (75 FR 32673), EPA has determined, or proposed to determine, that the 32 states covered by this proposal either have not submitted SIPs adequate to meet the requirements of 110(a)(2)(D)(i)(I) with respect to the 1997 and 2006 $PM_{2.5}$ NAAQS and the 1997 ozone NAAQS, or that the SIP provisions currently in place are not adequate to meet those requirements.

As described in section IV in this preamble, EPA is proposing a state-specific methodology to identify specific reductions that states in the eastern United States must make to satisfy the CAA section 110(a)(2)(D)(i)(I) prohibition on emissions that significantly contribute to nonattainment or interfere with maintenance in a downwind state. The proposed methodology uses state-specific inputs and focuses on the emissions reductions available in each individual state to address the Court's concern that the approach used in CAIR (which identified a single level of emissions achievable by the application of highly cost effective controls in the region) was insufficiently state specific. The proposed methodology uses air quality analysis to determine whether a state's contribution to downwind air quality problems is above specific thresholds. If a state's contribution does not exceed those thresholds, its contribution is found to be insignificant and it is no longer considered in the analysis. If a state's contribution exceeds those thresholds, EPA takes a second step that uses a multi-factor analysis that takes into account both air quality and cost considerations to identify the portion of a state's contribution that is significant or that interferes with maintenance. Section 110(a)(2)(D) requires states to eliminate the emissions that constitute this "significant contribution" and "interference with maintenance."

This proposed methodology for determining upwind state emission reduction responsibility is designed to be applicable to current and potential future ozone and $PM_{2.5}$ NAAQS. It is based on cost and air quality considerations that are common to any NAAQS, but also calls for evaluation of facts specific to a particular NAAQS. As a result, application of the methodology to a revised, more stringent NAAQS might lead to a determination that greater reductions in transported pollution from upwind states are reasonable than for a current, less stringent NAAQS.

To facilitate implementation of the requirement that significant contribution and interference with maintenance be eliminated, EPA developed state emissions budgets. By tying these budgets directly to EPA's quantification of each individual state's significant contribution and interference with maintenance, EPA directly linked the budgets to the mandate in section 110(a)(2)(D)(i)(I), and thus addressed the Court's concerns about the development of budgets for the CAIR. EPA also addressed these concerns by completely eschewing any consideration or reliance on Fuel Adjustment Factors and the existing allocation of Title IV allowances.

These new emissions budgets are based on the Agency's state-by-state analysis of each upwind state's significant contribution to nonattainment and interference with maintenance downwind. A state's emissions budget is the quantity of emissions that would remain after elimination of the part of significant contribution and interference with maintenance that EPA has identified in an average year (*i.e.*, before accounting for the inherent variability in power system operations).[2] EPA proposes SO_2 and NO_X budgets for each state covered for the 24-hour and/or annual average $PM_{2.5}$ NAAQS. EPA proposes an ozone season [3] NO_X budget for each state covered for the ozone NAAQS.

EPA recognizes that baseline emissions from a state can be affected by changing weather patterns, demand growth, or disruptions in electricity supply from other units. As a result, emissions could vary from year to year in a state where covered sources have installed all controls and taken all measures necessary to eliminate the state's significant contribution and interference with maintenance. As described in detail in section IV of this preamble, EPA proposes to account for the inherent variability in power system operations through "assurance provisions" based on state variability limits which extend above the state emissions budgets. *See* section V for a detailed discussion of the assurance provisions. The small amount of variability allowed takes into account the inherent variability in baseline emissions. Section IV in this preamble describes the proposed approach to significant contribution and interference with maintenance and the state emissions budgets and variability limits in detail.

EPA is also proposing FIPs to immediately implement the emission reduction requirements identified and quantified by EPA in this action. For some covered states, these FIPs will completely satisfy the emissions reductions requirements of 110(a)(2)(D)(i)(I) with respect to the 1997 and 2006 $PM_{2.5}$ NAAQS and the 1997 ozone NAAQS. The exception is for the 10 eastern states for which EPA has not completely quantified the total significant contribution or interference with maintenance with respect to the 1997 ozone NAAQS and the 15 states for which EPA has not completely quantified total significant contribution or interference with maintenance with respect to the 2006 $PM_{2.5}$ NAAQS in which case the FIPs would achieve measurable progress towards implementing that requirement.

The emissions reductions requirements (*i.e.*, the "remedy") that EPA is proposing to include in the FIPs responds to the Court's concerns that EPA had not shown that the CAIR reduction requirements would get all

[2] For the 10 states discussed above for which EPA has only quantified a minimum amount of emissions reductions needed to make measurable progress towards eliminating their significant contribution and interference with maintenance with respect to the 1997 8-hour ozone NAAQS, the emissions budget is the emissions that will remain after removal of those emissions.

[3] Consistent with the approach taken by the Ozone Transport Assessment Group (OTAG), the NO_X SIP call, and the CAIR, we propose to define the ozone season, for purposes of emissions reductions requirements in this rule, as May through September. We recognize that this ozone season for regulatory requirements differs from the official state-specific monitoring season.

necessary reductions "in the state" as required by section 110(a)(2)(D)(i)(I). The proposed FIPs include assurance provisions specifically designed to ensure that no state's emissions are allowed to exceed that specific state's budget plus the variability limit.

The proposed FIPs would regulate EGUs in the 32 covered states. EPA is proposing to regulate these sources through a program that uses state-specific budgets and allows intrastate and limited interstate trading. EPA is also taking comment on two alternative regulatory options. All options would achieve the emissions reductions necessary to address the emissions transport requirements in section 110(a)(2)(D)(i)(I) of the CAA.

The option EPA is proposing for the FIPs ("State Budgets/Limited Trading") would use state-specific emissions budgets and allow for intrastate and limited interstate trading. This approach would assure environmental results while providing some limited flexibility to covered sources. The approach would also facilitate the transition from CAIR to the Transport Rule for implementing agencies and covered sources.

The first alternative remedy option for which EPA requests comment would use state-specific emissions budgets and allow intrastate trading, but prohibit interstate trading. The second alternative remedy option, for which EPA also requests comment, would use state-specific budgets and emissions rate limits. See section V for further discussion of the remedy options.

The proposed remedy option and the first alternative, both of which are cap-and-trade approaches, would use new allowance allocations developed on a different basis from CAIR. Allowance allocations, like the state budgets described previously, would be developed based on the methodology used by EPA to quantify each state's significant contribution and interference with maintenance. *See* section IV for the proposed state budget approach and section V for proposed allowance allocation approaches.

In this action, EPA proposes to require reductions in SO_2 and NO_X emissions in the following 25 jurisdictions that contribute significantly to nonattainment in, or interfere with maintenance by, a downwind area with respect to the 24-hour $PM_{2.5}$ NAAQS promulgated in September 2006: Alabama, Connecticut, Delaware, District of Columbia, Georgia, Illinois, Indiana, Iowa, Kansas, Kentucky, Maryland, Massachusetts, Michigan, Minnesota, Missouri, Nebraska, New Jersey, New York, North Carolina, Ohio, Pennsylvania, Tennessee, Virginia, West Virginia, and Wisconsin.

EPA proposes to require reductions in SO_2 and NO_X emissions in the following 24 jurisdictions that contribute significantly to nonattainment in, or interfere with maintenance by, a downwind area with respect to the annual $PM_{2.5}$ NAAQS promulgated in July 1997: Alabama, Delaware, District of Columbia, Florida, Georgia, Illinois, Indiana, Iowa, Kentucky, Louisiana, Maryland, Michigan, Minnesota, Missouri, New Jersey, New York, North Carolina, Ohio, Pennsylvania, South Carolina, Tennessee, Virginia, West Virginia, and Wisconsin.

EPA also proposes to require reductions in ozone season NO_X emissions in the following 26 jurisdictions that contribute significantly to nonattainment in, or interfere with maintenance by, a downwind area with respect to the 1997 ozone NAAQS promulgated in July 1997: Alabama, Arkansas, Connecticut, Delaware, District of Columbia, Florida, Georgia, Illinois, Indiana, Kansas, Kentucky, Louisiana, Maryland, Michigan, Mississippi, New Jersey, New York, North Carolina, Ohio, Oklahoma, Pennsylvania, South Carolina, Tennessee, Texas, Virginia, and West Virginia.

As discussed previously, EPA also is proposing FIPs to directly regulate EGU SO_2 and/or NO_X emissions in the 32 covered states. The proposed FIPs would require the 28 jurisdictions covered for purposes of the 24-hour and/or annual $PM_{2.5}$ NAAQS to reduce SO_2 and NO_X emissions by specified amounts. The proposed FIPs would require the 26 states covered for purposes of the ozone NAAQS to reduce ozone season NO_X emissions by specified amounts.

In response to the Court's opinion in *North Carolina* v. *EPA*, EPA has coordinated the compliance deadlines for upwind states to eliminate emissions that significantly contribute to or interfere with maintenance in downwind areas with the NAAQS attainment deadlines that apply to the downwind nonattainment and maintenance areas. EPA proposes to require that all significant contribution to nonattainment and interference with maintenance identified in this action with respect to the $PM_{2.5}$ NAAQS be eliminated by 2014 and proposes an initial phase of reductions starting in 2012 (covering 2012 and 2013) to ensure that the reductions are made as expeditiously as practicable and that no backsliding from current emissions levels occurs when the requirements of the CAIR are eliminated. Sources will be required to comply by January 1, 2012 and January 1, 2014 for the first and second phases, respectively. With respect to the 1997 ozone NAAQS, EPA proposes to require an initial phase of NO_X reductions starting in 2012 to ensure that reductions are made as expeditiously as practicable. Sources will be required to comply by May 1, 2012 and May 1, 2014 for the first and second phases, respectively. EPA has determined, that for many states, these reductions will be sufficient to eliminate their significant contribution with respect to the 1997 ozone NAAQS. EPA intends to issue a subsequent proposal that would require all significant contribution and interference with maintenance be eliminated by a future date for the 1997 ozone NAAQS. *See* Table III.A–1 for proposed lists of covered state.

TABLE III.A–1—LISTS OF COVERED STATES FOR $PM_{2.5}$ AND 8-HOUR OZONE NAAQS

State	Covered for 24-hour and/or annual $PM_{2.5}$	Covered for 8-hour ozone
	Required to reduce SO_2 and NO_X	Required to reduce ozone Season NO_X
Alabama	X	X
Arkansas		X

Totals	28	26

As discussed previously, EPA is proposing new SO_2 and/or NO_X emissions budgets for each covered state. The budgets are based on the EPA's state-by-state analysis of each upwind state's significant contribution to nonattainment and interference with maintenance downwind, before accounting for the inherent variability in power system operations.

As discussed in detail in section IV, the proposed approach to significant contribution to nonattainment and interference with maintenance would group the 28 states covered for the 24-hour and/or annual $PM_{2.5}$ NAAQS in two tiers reflecting the stringency of SO_2 reductions required to eliminate that state's significant contribution to nonattainment and interference with maintenance. There would be a stringent SO_2 tier comprising 15 states ("group 1") and a moderate SO_2 tier comprising 13 states ("group 2"), with uniform stringency within each tier.[4] For these same 28 states, there would be one annual NO_X tier with uniform stringency of NO_X reductions across all 28 states. Similarly, for the 26 states covered for the ozone NAAQS there would be one ozone season NO_X tier with uniform stringency across all 26 states.

The proposed stringent SO_2 tier ("group 1") would include Georgia, Illinois, Indiana, Iowa, Kentucky, Michigan, Missouri, New York, North Carolina, Ohio, Pennsylvania, Tennessee, Virginia, West Virginia, and Wisconsin. The proposed moderate SO_2 tier ("group 2") would include Alabama, Connecticut, Delaware, District of Columbia, Florida, Kansas, Louisiana, Maryland, Massachusetts, Minnesota, Nebraska, New Jersey, and South Carolina.

As discussed previously, EPA proposes to require an initial phase of reductions starting in 2012 (covering 2012 and 2013) requiring SO_2 and NO_X reductions in the 28 states covered for 24-hour and/or annual $PM_{2.5}$ NAAQS. A second phase of reductions would be due in 2014, covering 2014 and thereafter. As described later, for certain states the 2014 reduction requirements would be more stringent, and for certain states would remain at the same level as the 2012 requirements.

For the 15 states in the stringent SO_2 tier ("group 1"), the 2014 phase would substantially increase the SO_2 reduction requirements (*i.e.*, these states would have smaller SO_2 emissions budgets starting in 2014), reflecting the greater reductions needed to eliminate the portion of significant contribution and interference with maintenance that EPA has identified in this proposal from these states with respect to the 24-hour $PM_{2.5}$ NAAQS. For the 13 states in the moderate SO_2 tier ("group 2"), the 2014 SO_2 emissions budgets would remain the same as the 2012 SO_2 budgets for these states.

The 2014 annual NO_X emissions budgets for all 28 states covered for the 24-hour and/or annual $PM_{2.5}$ NAAQS would remain the same as the 2012 annual NO_X budgets.

With respect to the ozone NAAQS, EPA is proposing a single phase of reductions which begins in 2012. Thus, the rule does not call for any adjustment to be made to the 2012 ozone season NO_X budgets for the 26 states covered for the ozone NAAQS. EPA intends to issue a subsequent proposal that would, among other things, address whether an additional phase of NO_X reductions is necessary to address all significant

[4] With regard to interstate trading, the two SO_2 stringency tiers would lead to two exclusive SO_2 trading groups. That is, states in SO_2 group 1 could not trade with states in SO_2 group 2.

contribution and interference with maintenance with respect to the 1997 ozone NAAQS. While this proposal assures downwind states that they will receive relief from upwind reductions that will help them achieve the NAAQS, EPA is committed to fulfilling its obligation to assure the downwind states that they receive the full relief they are entitled to under section 110(a)(2)(D). The Agency intends to quickly address any remaining significant contribution to nonattainment and interference with maintenance in a subsequent action that will also address a new more stringent ozone standard that is expected to be established by EPA later in 2010.

Tables III.A–2 and III.A–3 show projected Transport Rule emissions reductions for EGUs in all states that EPA proposes to cover.

TABLE III.A–2—PROJECTED SO_2 AND NO_X EGU EMISSIONS IN COVERED STATES WITH THE TRANSPORT RULE [5] COMPARED TO BASE CASE [6] WITHOUT TRANSPORT RULE OR CAIR

[Million tons]

	2012 Base case emissions	2012 Transport rule emissions	2012 Emissions reductions	2014 Base case emissions	2014 Transport rule emissions	2014 Emissions reductions
SO_2	8.4	3.4	5.0	7.2	2.6	4.6
Annual NO_X	2.0	1.3	0.7	2.0	1.3	0.7
Ozone Season NO_X	0.7	0.6	0.1	0.7	0.6	0.1

TABLE III.A–3—PROJECTED SO_2 AND NO_X EGU EMISSIONS IN COVERED STATES WITH THE TRANSPORT RULE COMPARED TO 2005 ACTUAL EMISSIONS

[Million tons]

	2005 Actual emissions	2012 Transport rule emissions	2012 Emissions reductions from 2005	2014 Transport rule emissions	2014 Emissions reductions from 2005
SO_2	8.9	3.4	5.5	2.6	6.3
Annual NO_X	2.7	1.3	1.4	1.3	1.4
Ozone Season NO_X	0.9	0.6	0.3	0.6	0.3

In addition to the emissions reductions shown previously, EPA projects other substantial benefits, as described in section IX in this preamble. Air quality modeling was used to quantify the improvements in $PM_{2.5}$ and ozone concentrations that are expected to result from the emissions reductions in 2014. The results of this modeling were used to calculate the average reduction in annual average $PM_{2.5}$, 24-hour average $PM_{2.5}$, and 8-hour ozone concentrations for monitoring sites in the eastern U.S. that are projected to be nonattainment in the 2014 base case. For annual $PM_{2.5}$ and 24-hour $PM_{2.5}$, the average reductions are 2.4 micrograms per cubic meter ($\mu g/m^3$) and 4.3 $\mu g/m^3$, respectively. The average reduction in 8-hour ozone at monitoring sites projected to be nonattainment in the 2014 base case is 0.3 parts per billion (ppb). The reductions in annual $PM_{2.5}$, 24-hour $PM_{2.5}$, and ozone concentrations for individual nonattainment and/or maintenance sites are provided in section IX.

Table III.A–4 compares projected EGU emissions with the Transport Rule to projected EGU emissions with CAIR.

TABLE III.A–4—SIMPLE COMPARISON OF SO_2 AND NO_X EMISSIONS FROM ELECTRIC GENERATING UNITS IN STATES IN THE CAIR OR TRANSPORT RULE REGIONS * FOR EACH RULE

		2005	2012		2014	
		Actual	Transport rule	CAIR **	Transport rule	CAIR **
SO_2 (Million Tons)		9.5	4.1	5.1	3.3	4.6
NO_X (Million Tons)	Annual	2.9	1.6	1.7	1.6	1.7
	Ozone Season	1.0	0.7	0.8	0.7	0.8

* Emissions totals include states covered by either the Transport Rule or CAIR. For $PM_{2.5}$ (SO_2 and annual NO_X), the following 30 states are included: AL, CT, DE, DC, FL, GA, IL, IN, IA, KS, KY, LA, MD, MA, MI, MN, MS, MO, NE, NJ, NY, NC, OH, PA, SC, TN, TX, VA, WV, WI. For ozone (ozone-season NO_X), the following 30 states are included: AL, AR, CT, DE, DC, FL, GA, IL, IN, IA, KS, KY, LA, MD, MA, MI, MS, MO, NJ, NY, NC, OH, OK, PA, SC, TN, TX, VA, WV, WI.

** CAIR SO_2 totals are interpolations from emissions analysis originally done for 2010 and 2015. CAIR NO_X totals are as originally projected for 2010. This CAIR modeling represents a scenario that differed somewhat from the final CAIR (the modeling did not include a regionwide ozone season NO_X cap and included $PM_{2.5}$ requirements for the state of Arkansas).

[5] Projected Transport Rule emissions result from individual stae budgets in the proposed approach and include some banking of allowances in 2012 adn use of that bank in 2014.

[6] EPA's base case EGU emissions modeling does not assume enforceable SO_2 or NO_X reductions attributed to the Transport Rule or CAIR. In this base case, a unit with existing SO_2 or NO_X control equipment, but without an enforceable federal or state control requirement, is allowed to choose its most economic approach to operation within existing Acid Rain Program requirements and may opt not to operate a control. *See* section IV.C.1 and the IPM Documentation for further information on the base case modeling.

In addition to discussion of EPA's proposed regulatory approach (discussed in sections IV and V), this preamble also covers the stakeholder outreach EPA conducted (section VI), SIP submissions (section VII), permitting (section VIII), projected benefits of the proposed rule (section IX), economic impacts (section X), end-use energy efficiency (section XI), and statutory and executive order reviews (section XII).

Table III.A–5 shows the results of the cost and benefits analysis for the proposed and alternate remedies. Further discussion of these results is contained in preamble section XII-A and in the Regulatory Impacts Analysis. A listing of health and welfare effects is provided in RIA Table 1–6. Estimates here are subject to uncertainties discussed further in the body of the document. The social costs are the loss of household utility as measured in Hicksian equivalent variation. The capital costs spent for pollution controls installed for CAIR were not included in the annual social costs since the Transport Rule did not lead to their installation. Those CAIR-related capital investments are roughly estimated to have an annual social cost less than $1.15 to $ 1.29 billion (under the two discount rates.)

Most of the estimated PM-related benefits in this rule accrue to populations exposed to higher levels of $PM_{2.5}$. Of these estimated PM-related mortalities avoided, about 80 percent occur among populations initially exposed to annual mean $PM_{2.5}$ level of 10 $\mu g/m^3$ and about 97 percent occur among those initially exposed to annual mean $PM_{2.5}$ level of 7.5 $\mu g/m^3$. These are the lowest air quality levels considered in the Laden *et al.* (2006) and Pope *et al.* (2002) studies, respectively. This fact is important, because as we estimate PM-related mortality among populations exposed to levels of $PM_{2.5}$ that are successively lower, our confidence in the results diminishes. However, our analysis shows that the great majority of the impacts occur at higher exposures.

TABLE III.A–5—SUMMARY OF ANNUAL BENEFITS, COSTS, AND NET BENEFITS OF VERSIONS OF THE PROPOSED REMEDY OPTION IN 2014 [a]

[Billions of 2006$]

Description	Preferred remedy—State budgets/ limited trading	Direct control	Intrastate trading
Social costs:			
3% discount rate	$2.03	$2.68	$2.49.
7% discount rate	$2.23	$2.91	$2.70.
Health-related benefits: [b, c]			
3% discount rate	$118 to $288 + B	$117 to $286 + B	$113 to $276 + B.
7% discount rate	$108 to $260 + B	$108 to $262 + B	$104 to $252 + B.
Net benefits (benefits-costs):			
3% discount rate	$116 to $286	$115 to $283	$110 to $273.
7% discount rate	$105 to $258	$105 to $259	$101 to $249.

Notes: (a) All estimates are rounded to three significant digits and represent annualized benefits and costs anticipated for the year 2014. For notational purposes, unquantified benefits are indicated with a "B" to represent the sum of additional monetary benefits and disbenefits. Data limitations prevented us from quantifying these endpoints, and as such, these benefits are inherently more uncertain than those benefits that we were able to quantify. (b) The reduction in premature mortalities account for over 90 percent of total monetized benefits. Benefit estimates are national. Valuation assumes discounting over the SAB-recommended 20-year segmented lag structure described in Chapter 5. Results reflect 3 percent and 7 percent discount rates consistent with EPA and OMB guidelines for preparing economic analyses (U.S. EPA, 2000; OMB, 2003). The estimate of social benefits also includes CO_2-related benefits calculated using the social cost of carbon, discussed further in Chapter 5. Benefits are shown as a range from Pope *et al.* (2002) to Laden *et al.* (2006). Monetized benefits do not include unquantified benefits, such as other health effects, reduced sulfur deposition or visibility. These models assume that all fine particles, regardless of their chemical composition, are equally potent in causing premature mortality because there is no clear scientific evidence that would support the development of differential effects estimates by particle type. (c) Not all possible benefits or disbenefits are quantified and monetized in this analysis. B is the sum of all unquantified benefits and disbenefits. Potential benefit categories that have not been quantified and monetized are listed in RIA Table 1–4.

B. Background

1. What is the source of EPA's authority for this action?

The statutory authority for this action is provided by the CAA, as amended (42 U.S.C. 7401 *et seq.*). Relevant portions of the CAA include, but are not necessarily limited to, sections 110(a)(2)(D), 110(c)(1), and 301(a)(1).

Section 110(a)(2)(D) of the CAA, often referred to as the "good neighbor" provision of the Act, requires states to prohibit certain emissions because of their impact on air quality in downwind states. Specifically, it requires all states, within 3 years of promulgation of a new or revised NAAQS, to submit SIPs that:

(D) Contain adequate provisions—

(i) Prohibiting, consistent with the provisions of this subchapter, any source or other type of emissions activity within the State from emitting any air pollutant in amounts which will—

(I) Contribute significantly to nonattainment in, or interfere with maintenance by, any other State with respect to any such national primary or secondary ambient air quality standard, or

(II) Interfere with measures required to be included in the applicable implementation plan for any other State under part C of this subchapter to prevent significant deterioration of air quality or to protect visibility.

(ii) Insuring compliance with the applicable requirements of sections 7426 and 7415 of this title (relating to interstate and international pollution abatement). 42 U.S.C. 7410(a)(2)(D).

This proposal addresses the requirement in section 110(a)(2)(D)(i)(I) regarding the prohibition of emissions within a state that significantly contribute to nonattainment or interfere with maintenance of the NAAQS in any other state. As discussed in greater detail later, EPA has previously issued two rules interpreting and clarifying the requirements of section 110(a)(2)(D)(i)(I). The NO_X SIP Call, promulgated in 1998, was largely upheld by the U.S. Court of Appeals for the DC Circuit in *Michigan* v. *EPA*, 213 F.3d 663 (DC Cir. 2000). The CAIR, promulgated in 2005, was remanded by the DC Circuit in *North Carolina* v. *EPA*, 531 F.3d 896 (DC Cir. 2008), *modified on reh'g*, 550 F.3d. 1176 (DC Cir. 2008). These decisions provide additional guidance regarding the requirements of section 110(a)(2)(D)(i)(I) and are discussed later in this section.

Section 301(a)(1) of the CAA gives the Administrator of EPA general authority to "prescribe such regulations as are necessary to carry out [her] functions under this chapter." 42 U.S.C. 7601(a)(1). Pursuant to this section, EPA has authority to clarify the applicability of CAA requirements. In this action,

EPA is clarifying the applicability of section 110(a)(2)(D)(i)(I) by proposing to identify SO_2 and NO_X emissions that each affected state must prohibit pursuant to that section with respect to the $PM_{2.5}$ NAAQS promulgated in 1997 and 2006 and the 8-hour ozone NAAQS promulgated in 1997. The improvements in air quality that would result from the reductions in upwind state emissions that EPA is proposing to require would assist downwind states affected by transported pollution in developing, pursuant to section 110 of the CAA, their SIPs to provide for expeditious attainment and maintenance of the NAAQS.

Section 110(a) of the CAA assigns to each state both the primary responsibility for attaining and maintaining the NAAQS within such state, 42 U.S.C. 7410(a)(1), and the primary responsibility for prohibiting emissions activity within the state which will significantly contribute to nonattainment or interfere with maintenance in a downwind area. 42 U.S.C. 7410(a)(2)(D)(i)(I). States fulfill these CAA obligations through the SIP process described in section 110(a) of the Act.

Section 110(c)(1) of the Act, however, requires EPA to act when a state has not been able to or has not fulfilled its obligation to submit a SIP that meets the requirements of the Act. Specifically, section 110(c)(1) provides that: The Administrator shall promulgate a Federal implementation plan at any time within 2 years after the Administrator—

(A) Finds that a State has failed to make a required submission or finds that the plan or plan revision submitted by the State does not satisfy the minimum criteria established under subsection (k)(1)(A) of this section, or

(B) Disapproves a State implementation plan submission in whole or part, unless the State corrects the deficiency, and the Administrator approves the plan or plan revision, before the Administrator promulgates such Federal implementation plan.

42 U.S.C. 7410(c)(1). Section 110(k)(1)(A), in turn, calls for the Administrator to establish criteria for determining whether SIP submissions are complete. 42 U.S.C. 7410(k)(1)(A).

As discussed in greater detail in section VII, for all states covered by the FIPs proposed in this action, EPA either has taken, has proposed to take, or believes it may need to take one of the following actions with respect to the 1997 ozone NAAQS, the 1997 $PM_{2.5}$ NAAQS and/or the 2006 $PM_{2.5}$ NAAQS: (1) Find that the state has failed to make a SIP submission required by section 110(a)(2)(D)(i)(I) or section 110(k)(5) of the Act; (2) find that such a SIP submission is incomplete; or (3) disapprove such a SIP submission. Once EPA has taken one of the these actions, pursuant to section 110(c)(1), it has authority to promulgate a FIP directly implementing the requirements of section 110(a)(2)(D)(i)(I), provided the state has not submitted and EPA has not approved a SIP submission that corrects the SIP deficiency prior to promulgation of the FIP.

2. What air quality problems does this proposal address?

a. Fine Particles

Fine particles are associated with a number of serious health effects including premature mortality, aggravation of respiratory and cardiovascular disease (as indicated by increased hospital admissions, emergency room visits, health-related absences from school or work, and restricted activity days), lung disease, decreased lung function, asthma attacks, and certain cardiovascular problems. *See* EPA, Air Quality Criteria for Particulate Matter (EPA/600/P–99/002bF, October 2004) at 9.2.2.3. *See* also integrated science assessment for the PM NAAQS review, December 2009, *http://cfpub.epa.gov/ncea/cfm/recordisplay.cfm?deid=216546*. Individuals particularly sensitive to fine particle exposure include older adults, people with heart and lung disease, and children. This rule, and the NAAQS to which it is related, consider the effects of fine particles on vulnerable populations (*see* further discussion in section XII.G and section XII.J of this notice). More detailed information on health effects of fine particles can be found on EPA's Web site at: *http://epa.gov/pm/standards.html*.

In addition to effects on public health, fine particles are linked to a number of public welfare effects. First, $PM_{2.5}$ are the major cause of reduced visibility (haze) in parts of the United States, including many of our national parks and wilderness areas. For more information about visibility, visit EPA's Web site at *http://www.epagov/visibility*. Second, particles can be carried over long distances by wind and then settle on ground or water. The effects of this settling include: Making lakes and streams acidic; changing the nutrient balance in coastal waters and large river basins; depleting the nutrients in soil; damaging sensitive forests and farm crops; and affecting the diversity of ecosystems. More information about these effects is available at EPA's Web site at *http://www.epa.gov/acidrain/effects/index.html*. Finally, particle pollution can stain and damage stone and other materials, including culturally important objects such as statues and monuments.

In 1997, EPA revised the NAAQS for PM to add new annual average and 24-hour standards for fine particles, using $PM_{2.5}$ as the indicator (62 FR 38652). These revisions established an annual standard of 15 $\mu g/m^3$ and a 24-hour standard of 65 $\mu g/m^3$. During 2006, EPA revised the air quality standards for $PM_{2.5}$. The 2006 standards decreased the level of the 24-hour fine particle standard from 65 $\mu g/m^3$ to 35 $\mu g/m^3$, and retained the annual fine particle standard at 15 $\mu g/m^3$.

In the preamble to the final rule for CAIR in May 2005, EPA discussed ambient monitoring for 2001–2003, the most recent 3-year period available at the time. These results showed widespread exceedances of the 15 $\mu g/m^3$ annual $PM_{2.5}$ standard in the eastern United States, with additional exceedances in parts of California and one county in Montana. At that time, 82 counties in the U.S. had at least one monitor that violated the 1997 annual $PM_{2.5}$ standard.

The $PM_{2.5}$ ambient air quality monitoring for the 2006–2008 period (most recent available) shows significant improvements. Nonetheless, areas which continue to violate the 15 $\mu g/m^3$ annual $PM_{2.5}$ standard are located across a significant portion of the eastern half of the United States, in parts of California and one county in Arizona. Based on these nationwide data, 23 counties have at least one monitor that violates the annual $PM_{2.5}$ standard.

The $PM_{2.5}$ ambient air quality monitoring for this same 2006–2008 time period shows that areas violating the 2006 24-hour $PM_{2.5}$ standard of 35 $\mu g/m^3$ (*i.e.*, the revised 2006 standard for 24-hour $PM_{2.5}$) are located across much of the eastern half of the United States, in parts of California, and in some counties in several other western states—Alaska, Washington, Oregon, Utah, and Arizona. Based on these nationwide data, 52 counties have at least one monitor that violates the 24-hour $PM_{2.5}$ standard.

EPA believes that a great deal of the improvement in $PM_{2.5}$ annual and 24-hour concentrations in the eastern U.S. can be attributed to EGU SO_2 reductions achieved due to the CAIR. While the CAIR requirements related to SO_2 did not begin until 2010, many actions were taken by EGU owners and operators in anticipation of those requirements. Emissions of SO_2 from EGUs covered by the CAIR that were also in the acid rain

program (under CAA Title IV) tracking system decreased from 10.2 million tons in 2005 to 7.6 million tons in 2008. Almost all of these emissions reductions were achieved in the areas of the eastern United States covered by the CAIR. See *http://www.epa.gov/airmarkt/progress/ARP_4.html*. EPA believes that there would be substantially more nonattainment counties for both the annual and 24-hour standards if the CAIR were not in effect.

As required by the CAA, and in response to litigation over the 2006 standards, EPA is currently conducting a review of the 2006 $PM_{2.5}$ standards. Information and documents related to this review are available at: *http://epa.gov/ttn/naaqs/standards/pm/s_pm_index.html*. EPA expects to complete this review and to publish any revised standards that may result from the review by October 2011. EPA is planning to propose the revised standards by February 2011.

b. Ozone

Short-term (1- to 3-hour) and prolonged (6- to 8-hour) exposures to ambient ozone have been linked to a number of adverse health effects. At sufficient concentrations, short-term exposure to ozone can irritate the respiratory system, causing coughing, throat irritation, and chest pain. Ozone can reduce lung function and make it more difficult to breathe deeply. Breathing may become more rapid and shallow than normal, thereby limiting a person's normal activity. Ozone also can aggravate asthma, leading to more asthma attacks that may require a doctor's attention and the use of additional medication. Increased hospital admissions and emergency room visits for respiratory problems have been associated with ambient ozone exposures. Longer-term ozone exposure can inflame and damage the lining of the lungs, which may lead to permanent changes in lung tissue and irreversible reductions in lung function. A lower quality of life may result if the inflammation occurs repeatedly over a long time period (such as months, years, or a lifetime). There is also recent epidemiological evidence indicating that there is a correlation between short-term ozone exposure and premature mortality.

People who are particularly susceptible to the effects of ozone include people with respiratory diseases, such as asthma. Those who are exposed to higher levels of ozone include adults and children who are active outdoors. This rule, and the NAAQS which it is related to, consider the effects of ozone on vulnerable populations (*see* further discussion in section XII.G and section XII.J of this notice).

In addition to causing adverse health effects, ozone affects vegetation and ecosystems, leading to reductions in agricultural crop and commercial forest yields; reduced growth and survivability of tree seedlings; and increased plant susceptibility to disease, pests, and other environmental stresses (*e.g.*, harsh weather). In long-lived species, these effects may become evident only after several years or even decades and have the potential for long-term adverse impacts on forest ecosystems. Ozone damage to the foliage of trees and other plants can also decrease the aesthetic value of ornamental species used in residential landscaping, as well as the natural beauty of our national parks and recreation areas. More detailed information on effects of ozone can be found at the following EPA Web site: *http://www.epa.gov/ttn/naaqs/standards/ozone/s_o3_index.html*.

In 1997, at the same time we revised the $PM_{2.5}$ standards, EPA issued its final action to revise the NAAQS for ozone (62 FR 38856) to establish new 8-hour standards. In this action published on July 18, 1997, we promulgated identical revised primary and secondary ozone standards that specified an 8-hour ozone standard of 0.08 parts per million (ppm). Specifically, the standards require that the 3-year average of the fourth highest 24-hour maximum 8-hour average ozone concentration may not exceed 0.08 ppm. In general, the 8-hour standards are more protective of public health and the environment and more stringent than the pre-existing 1-hour ozone standards.

At the time EPA published the CAIR and the CAIR FIP rulemakings, wide geographic areas, including most of the nation's major population centers, experienced ozone levels that violated the 1997 NAAQS of 8-hour ozone 0.08 ppm (effectively 0.084 ppm as a result of rounding). These areas included much of the eastern part of the United States and large areas of California. The EPA published the 8-hour ozone attainment and nonattainment designations in the **Federal Register** on April 30, 2004 (69 FR 23858). These designations, based on ozone season monitoring data for the 2001–2003 time period, resulted in 112 areas designated as nonattainment. As of December 2009, significant emissions reductions have allowed 58 of the original 112 nonattainment areas to be re-designated to attainment. In addition, a number of areas still designated as nonattainment ozone monitoring data for 2006–2008 (most recent data available) show levels below the standard. EPA believes a number of factors contributed to NO_X emissions reductions subsequent to the 2001–2003 time period. First, EGU emissions were substantially reduced as EGUs in the eastern U.S. came into compliance with the NO_X SIP Call. A series of progress reports discussing the effect of the NO_X SIP Call reductions can be found on EPA's Web site at: *http://www.epa.gov/airmarkets/progress/progress-reports.html*. Additional information on emissions and air quality trends are available in EPA's 2007 and 2008 air quality trends reports, which are available at: *http://www.epa.gov/airtrends/*.

Second, mobile source emissions standards for onroad gasoline and vehicle emissions standards began to reduce mobile source emissions as the fleet began turning over vehicles to meet tightened NO_X emissions standards. Continued improvement in ozone is expected with continued reductions in mobile source emissions.

On March 12, 2008, EPA published a revision to the 8-hour ozone standard, lowering the level from 0.08 ppm to 0.075 ppm. On September 16, 2009, EPA announced it would reconsider these 2008 ozone standards. The purpose of the reconsideration is to ensure that the ozone standards are clearly grounded in science, protect public health with an adequate margin of safety, and are sufficient to protect the environment. EPA proposed revisions to the standards on January 19, 2010 (75 FR 2938) and will issue final standards soon. Information on the 2008 revisions to the ozone standard, and on all subsequent activity based on the reconsideration, is available at: *http://www.epa.gov/air/ozonepollution/actions.html#sep09s*.

3. Which NAAQS does this proposal address?

This proposed action addresses the requirements of CAA section 110(a)(2)(D)(i)(I) as they relate to:

(1) The 1997 annual $PM_{2.5}$ standards,

(2) The 2006 daily $PM_{2.5}$ standards, and

(3) The 1997 ozone standards

The original CAIR and CAIR FIP rules, which pre-dated the 2006 standards, addressed the 1997 ozone and $PM_{2.5}$ standards only. The 1997 8-hour ozone standard is 0.08 ppm. The 1997 $PM_{2.5}$ standards promulgated in 1997 established a 15 $\mu g/^3$ standard for 24-hour $PM_{2.5}$ and a 65 $\mu g/m^3$ standard for annual $PM_{2.5}$. In 2006, the 24-hour $PM_{2.5}$ standard was lowered to 35 $\mu g/m^3$ and the 15 $\mu g/m^3$ annual $PM_{2.5}$ standard was left unchanged.

For this proposal, EPA fully addresses the requirements of CAA section 110(a)(2)(D)(i)(I) for the annual $PM_{2.5}$ standard of 15 μg/m³. For the 24-hour standard of 35 μg/m³ and for the 1997 8-hour ozone standard of 0.08 ppm, EPA fully addresses the CAA section 110(a)(2)(D)(i)(I) requirements for some states, but for the remaining states EPA will address whether further requirements are needed.

This action does not address the CAA section 110(a)(2)(D)(i)(I) requirements for the revised ozone standards promulgated in 2008. These standards are currently under reconsideration. We are, however, actively conducting the technical analyses and other work needed to address interstate transport for the reconsidered ozone standard as soon as possible. We intend to issue as soon as possible a proposal to address the transport requirements with respect to the reconsidered standard.

4. EPA Transport Rulemaking History

a. CAA Provisions

For almost 40 years, Congress has focused major efforts on curbing ground-level ozone. In 1970, Congress amended the CAA to require, in Title I, that EPA issue and periodically review and, if necessary, revise NAAQS for ubiquitous air pollutants (sections 108 and 109). Congress required the states to submit SIPs to attain and maintain those NAAQS, and Congress included, in section 110, a list of minimum requirements that SIPs must meet. Congress anticipated that areas would attain the NAAQS by 1975.

In 1977, Congress amended the CAA by providing, among other things, additional time for areas that were not attaining the ozone NAAQS to do so, as well as by imposing specific SIP requirements for those nonattainment areas. These provisions first required the designation of areas as attainment, nonattainment, or unclassifiable, under section 107; and then required that SIPs for ozone nonattainment areas include the additional provisions set out in part D of Title I, as well as demonstrations of attainment of the ozone NAAQS by either 1982 or 1987 (section 172).
