Section N.4: Notes, Comments, and Explanations
EU01: Combine EU01 and EU02 as SCC includes all charge handling activites
EU01: Change name from Scrap Steel Storage to Change Handling to match SCC and industry norms
EU01: APCD CU01 added to address secondary capture of emissions
EU03 and EU04: Not installed at this time
EU05: Change name from Refractory Burner #1 to Ladle Preheater #1 to better identify emission unit
EU06: Change name from Refractory Burner #2 to Ladle Preheater #2 to better identify emission unit
EU05 and EU06: APCD CU01 added to address secondary capture of emissions

Section N.4: Notes, Comments, and Explanations
EU11-EU16: Change operating limit to 91,586 tpy; incorrect assumption to split 50:50
EU11, EU12 and EU15: Not installed at this time
EU11-EU16: Change maximum hourly capacity as 25.3 tph for each group; incorrect assumption to split 50:50
EU13 and EU14: Combine to a single EU ID EU13 and name "Molten Metal Transfer"
EU17: Change description from "Melt Shop Baghouse Waste Dust Silo" to "Core/Mold Baghouse Waste Dust Silo"
EU19: Change hourly capacity to 25 tph to reflect pnuematic conveying truck capacity
EU20: Change hourly capacity to 25 tph to reflect pnuematic conveying truck capacity
EU13, EU14, EU18: Added Control Device ID CU01 as secondary capture

Section N.4: Notes, Comments, and Explanations
EU21: Change hourly capacity to 25 tph to reflect pnuematic conveying truck capacity.
EU21 - EU30: Combine into a single emission unit described as "Moldmaking and Sand Handling" with Emission Unit ID EU21 to match SCC description

Section N.4: Notes, Comments, and Explanations
EU31 thru EU34: Combine into a single emission unit identied as "Moldmaking and Sand Preparation (EU21)"
EU33-EU34: Change maximum hourly capacity as 197 tph for the group; incorrect assumption to split 50:50
EU35A: Change hourly capacity to 25 tph to reflect pnuematic conveying truck capacity
EU35B: Change hourly capacity to 25 tph to reflect pnuematic conveying truck capacity
EU35A and EU35B: Bin Vents (CU18 and CU19) vent inside with secondary capture via CU08 through stack ST09
EU34: Not installed at this time

Section N.4: Notes, Comments, and Explanations
EU48 thru EU49: Combine into a single emission unit identied as "Moldmaking and Sand Preparation (EU21)"
EU50-EU51: Change maximum hourly capacity to 25.3 tph for group; incorrect assumption to split 50:50
EU41, EU42,EU46, EU47, EU49: Not installed at this time

Section N.4: Notes, Comments, and Explanations
EU50-EU51: Change maximum hourly capacity to 25.3 tph for group; incorrect assumption to split 50:50
EU51 and EU58: Not installed at this time

Section N.4: Notes, Comments, and Explanations
EU61 and EU62: To match SCC, remove shot maximum hourly capacity and replace with metal hourly capacity for the group
EU64: Change name for Grinding #1 to Autogrinder #1, replace capacity with metal hourly capacity for the group
EU65: Change name for Grinding #2 to Autogrinder #2, replace capacity with metal hourly capacity for the group
EU66 and EU67: Combine and describe as "Machining " and identify as EU66
EU66-EU67: Cartridge Filters (CU13a-j) vent inside with secondary capture via Paint Line Fabric Filter stack ST15c
EU68: Change name to Paint Line #3
EU62, EU65 and E70: Emission Unit is not installed
EU69: Change name to Paint Line #2
EU71: Change name to Paint Line #1

Section N.4: Notes, Comments, and Explanations
EU75: Gasoline tank is not installed
EU77 - Change Paved Roadways from EU76 to EU77 as EU76 is already identified as the ID for the diesel storage tank.

Executive Summary

This report contains the results of VOC emission testing during phenolic urethane Cold Box core making. All testing was conducted in the Technikon, LLC Production foundry core making facility.

The test was divided into three segments, core mixing, core blowing, and core storage. Core mixing was performed using a Redford/Carver 50 pound core sand mixer. During the core-blowing portion of the test, the gassing and purge emissions and the "fugitive" emissions were measured together. The storage emissions represent the VOCs released to the environment from the time of core removal from the core box until the core is used to produce a casting. For this study, a five (5) hour storage time was established. All components of mold making were conducted within enclosures meeting the criteria for a temporary total enclosure (TTE) as specified in US EPA Method 204.

Each test segment consisted of nine (9) replicate runs. Samples were collected on sorbent tubes during each run for selected VOCs and HAPs for subsequent laboratory analysis in accordance with US-EPA Method 18. All sampling locations were consistent with US EPA Method 1 except for core storage. The storage segment of the test used a laminar flow-through enclosure to sweep all of the emissions to the Method 18 sampling manifold. US EPA Method 25A, Total Gaseous Organic Concentration (TGOC), was used to monitor all segments of the test.

The table below summarizes the results for each of the test segments in lbs/lb of binder.

Analyte	Mixing	Gas/Purge Fugitives	Storage	Total
TGOC as Propane	0.0041	NA	NA	NA
HC as Hexane	0.0021	0.0752	0.0171	0.0944
Sum of VOCs	0.0001	0.0014	0.0008	0.0023
Sum of HAPs	0.0001	0.0014	0.0008	0.0023
Sum of POMs	ND	0.0010	0.0007	0.0017

NA: Not Applicable. **TGOC**: measures all carbon-containing organic compounds. The predominant organic in these test-segments was the triethylamine catalyst which was not a target analyte.

It must be noted that the reference testing performed is not suitable for use as emission factors or for purposes other than evaluating the relative emission reductions associated with the use of alternative materials, equipment, or processes. The emissions measurements are unique to the specific castings produced, materials used, and testing methodology associated with these tests, and should not be used as the basis for estimating emissions from actual commercial foundry applications.

THIS PAGE INTENTIONALLY LEFT BLANK

1.0 Introduction

1.1 Background

Technikon LLC is a privately held contract research organization located in McClellan, California, a suburb of Sacramento. Technikon offers emissions research services to industrial and government clients specializing in the metal casting and mobile emissions areas. Technikon operates the Casting Emission Reduction Program (CERP). CERP is a cooperative initiative between the Department of Defense (US Army) and the United States Council for Automotive Research (USCAR). Its purpose is to evaluate alternative casting materials and processes that are designed to reduce air emissions and/or produce more efficient casting processes. Other technical partners directly supporting the project include: the American Foundry Society (AFS); the Casting Industry Suppliers Association (CISA); the US Environmental Protection Agency (USEPA); and the California Air Resources Board (CARB).

1.2 Technikon Objectives

The primary objective of Technikon is to evaluate materials, equipment, and processes used in the production of metal castings. Technikon's facility was designed to evaluate alternate materials and production processes designed to achieve significant air emission reductions, especially for the 1990 Clean Air Act Amendment. The facility has two principal testing arenas: a Pre-Production Foundry designed to measure airborne emissions from individually poured molds, and a Production Foundry designed to measure air emissions in a continuous full scale production process. Each of these testing arenas has been specially designed to facilitate the collection and evaluation of airborne emissions and associated process data.

The Production Foundry provides simultaneous detailed individual emission measurements using methods based on USEPA protocols for the melting, pouring, sand preparation, mold making, and core making processes. The core making area of the Production foundry contains three core blowers, a Georg Fischer for the preparation of automotive block cores, a Redford that is used for the production of step cores, and a second smaller Redford to produce dogbone tensile test specimens.

It must be noted that the results from the reference and product testing performed are not suitable for use as emission factors or for other purposes other than evaluating the relative emission reductions associated with the use of alternative materials, equipment, or manufacturing processes. The emissions measurements are unique to the specific castings produced, materials used, and testing methodology associated with these tests. These measurements should not be used as the basis for estimating emissions from actual commercial foundry applications.

1.3 Report Organization

This report has been designed to document the methodology and results of a specific test plan that was used to evaluate VOC emissions from the ISOCURE® core making process. Section 2 of this report includes a summary of the methodologies used for data collection and analysis,

emission calculations, QA/QC procedures, and data management and reduction methods. Specific data collected during this test are summarized in Section 3 of this report, with detailed data included in Appendix B of this report. Section 4 of this report contains a discussion of the results, and Section 5 contains recommendations for further testing.

The raw data for this test series are included in a folder that is maintained at the Technikon facility.

1.4 Specific Test Plan and Objectives

This report contains the results of testing performed to provide data on selected VOC emissions from the core making process. Table 1-1 provides a summary of the test plan for the mixing, core making, and storage phase. The details of the approved test plan are included in Appendix A.

Table 1-1 Test Plan Summary

	Test Plan
Type of Process tested	Core Making Emissions Study
Test Plan Number	1409-123
Binder System	Ashland ISOCURE® 305/904
Number of tests	9 each at core blowing, core mixing, and core storage
Test Date	8/19/02 > 9/13/02
Emissions Measured	TGOC as Propane, HC as Hexane, o-Cresol, Phenol, Formaldehyde, Naphthalene, 1-Me Naphthalene, 2-Me Naphthalene
Process Parameters Measured	Sand, and Binder Weights, Incoming Sand Temperature, Sand Mixing Time, Core Machine Cycle Time
Source Parameters Measured	Exhaust Duct Temperature, Pressure, and Volumetric Flow Rate

2.0 Test Methodology

2.1 Description of Process and Testing Equipment

Figure 2-1 is a diagram of the core making process and testing equipment.

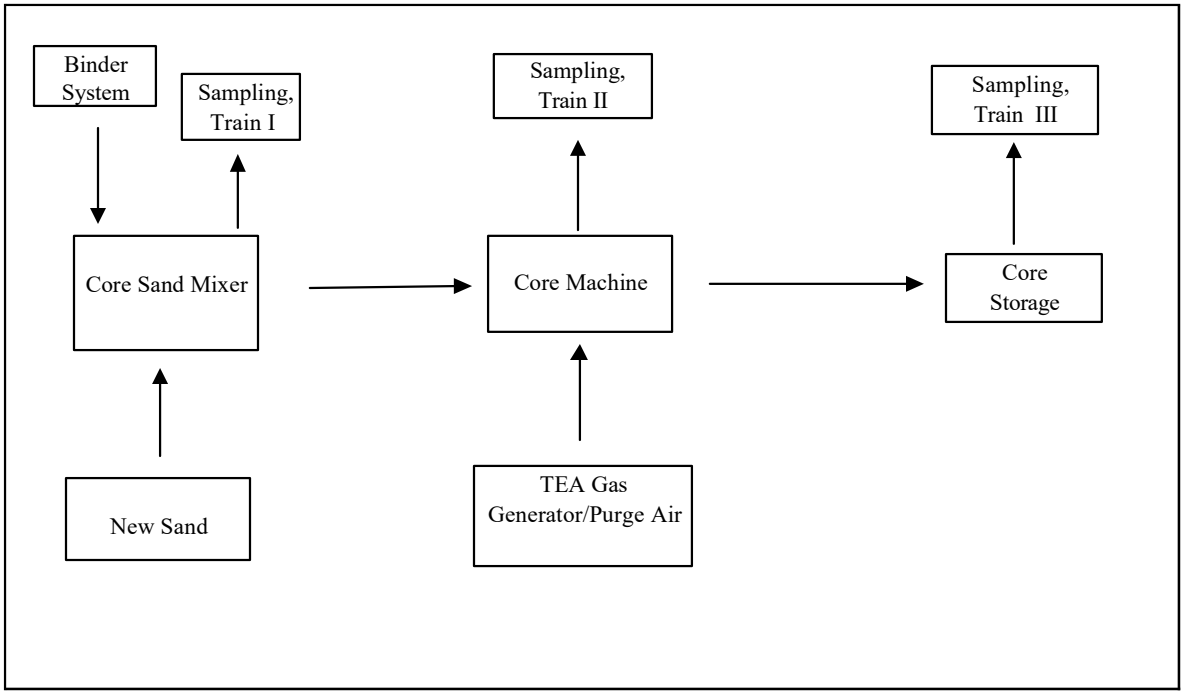

Figure 2-1 Core Making and Testing Process

2.2 Description of Testing Program

The specific steps used in this sampling program are summarized below:

1. **Test Plan Review and Approval:** The proposed test plan was reviewed by the Technikon staff and the CERP Steering Committee, and approved.

2. **Core Preparation**: Step cores were prepared for this test in the Production foundry core room area. The sand and binder were mixed in a Paddle Wheeled Sand Mixer, and then introduced (blown) into the core tooling of the Redford-Carver core machine. The core-making machine was contained in a permanent total enclosures meeting US EPA Method 204 criteria. A weighed amount of the catalyst triethylamine (TEA) gas was heated to 84°F and allowed to expand into the sand in the core box to cure the core. Finally, purge air, heated to 80°F, was blown through the sand mixture in the core box. All these gases

are exhausted to a wet gas scrubber charged with sulfuric acid at pH 4 or less. Step cores are fabricated in a single cavity core box. One blow produces a single step core.

3. **Individual Sampling Events:** Sampling to determine the core making emissions consisted of three (3) segments. The mixing emissions were collected from a Paddle Wheeled 50 pound core sand mixer for seven (7) minutes. The mixed sand was dumped into the Redford Carver sand storage hopper. Air samples were collected during the seven (7) minute mix cycle prior to dumping. During the production of step cores, air sample were also collected to determine the amount of solvents being vented off the core process. The samples were collected during each of the nine (9) thirty (30) minute runs that comprised this portion of the test. The storage segment of the test consisted of placing four (4) cores in the flow-through storage enclosures as soon as they were removed from the core machine. The storage enclosures were sealed and sampling begun. A five (5) hour integrated sample was collected. All of the enclosures used during this test meet or exceed US-EPA Method 204 criteria for Temporary Total Enclosures.

Sand Mixing

Core Making

Core Storage

4. **Process Parameter Measurements:** Table 2-1 lists the process parameters that are monitored during each test. The analytical equipment and methods used are also listed.

Table 2-1 Process Parameters Measured

Parameter	Analytical Equipment and Methods
Binder Weight	Mettler PJ8000 Digital Scale (Gravimetric)
Core Sand Weight	Simpson IQ-800-3A Digital Scale

5. **Air Emissions Analysis:** The specific sampling and analytical methods used in the core sand mixing, making, and core storage tests are based on the USEPA reference methods shown in Table 2-2. The details of the specific testing procedures and their variance from the reference methods, if any, are included in the Technikon Standard Operating Procedures.

Table 2-2 Sampling and Analytical Methods

Measurement Parameter	Test Method*
Port location	EPA Method 1
Number of traverse points	EPA Method 1
Gas velocity and temperature	EPA Method 2
HC as Hexane Benzene, Naphthalene, Formaldehyde, o-Cresol, Phenol,	EPA Method 18, NIOSH 1500, NIOSH 2002, TO-11
TGOC (THC) as Propane concentration	EPA Method 25A
Volatile Matter content	EPA Method 24

* These methods were specifically modified to meet the testing objectives of the CERP Program.

6. **Data Reduction, Tabulation and Preliminary Report Preparation:** The analytical results of the emissions tests provide the mass of each analyte in the sample. For the core-blowing segment of the test, the total mass of the analyte emitted is calculated by multiplying the mass of analyte in the sample times the ratio of the sample volume to the total stack gas volume during the test. The total stack gas volume is calculated from the measured stack gas velocity and duct diameter. The total mass of analyte is then divided by the weight of the binder used to provide emissions data in pounds of analyte per pound of binder.

In the case of the storage segment of this test, the stack parameters are replaced by the total volume of gas flowing through the storage enclosure during each sampling period. The total flow rate through the enclosure was controlled with critical orifices. The total mass of the analyte emitted is then calculated by multiplying the measured mass of analyte in the sample times the ratio of sample volume to total gas volume over the same time period.

7. **Report Preparation and Review:** The Preliminary Draft Report is reviewed by the Process Team and Emissions Team to ensure its completeness, consistency with the test plan, and adherence to the prescribed QA/QC procedures. Appropriate observations, conclusions and recommendations are added to the report to produce a Draft Report. The Draft Report is reviewed by the Vice President-Measurement Technologies, the Vice President-Operations. Comments are incorporated into a Final Report prior to final signature approval and distribution.

2.3 Quality Assurance and Quality Control (QA/QC) Procedures

Detailed QA/QC and data validation procedures for the process parameters, stack measurements, and laboratory analytical procedures are included in the Technikon Standard Operating Procedures. In order to ensure the timely review of critical quality control parameters, the following procedures are followed:

~ Immediately following the individual sampling events performed for each test, specific process parameters are reviewed by the Manager - Process Engineering to ensure that the parameters are maintained within the prescribed control ranges. Where data are not within the prescribed ranges, the Manager - Process Engineering and the Vice President-Operations determine whether the individual test samples should be invalidated or flagged for further analysis following review of the laboratory data.

~ The source (stack) and sampling parameters, analytical results and corresponding laboratory QA/QC data are reviewed by the Emissions Measurement Team to confirm the validity of the data. The VP-Measurement Technologies reviews and approves the recommendation, if any, that individual sample data should be invalidated. Invalidated data are not used in subsequent calculations.

3.0 Test Results

The average emission results, in pounds per pound of binder used, are presented in Table 3-1.

The average emission results, in pounds per ton of sand used, are presented in Table 3-2.

The amount of available VOCs for this binder system was determined using a method based on US EPA Method 24 and found to be 0.33 pounds per pound of binder or 33% of the binder weight. This data is presented in Table 3-3

Table 3-4 contains average test process and source data. The total binder weight and the total core weight were calculated from the total amount of sand and the percent binder used in each section of the test.

Appendix B contains the detailed emissions and process data.

Figure 3-1 shows the data from Table 3-1 while Figure 3-2 shows the data from Table 3-2.

THIS PAGE INTENTIONALLY BLANK

4.0 Discussion of Results

Volatile organic compound (VOC), hazardous air pollutant (HAP), and polycyclic organic material (POM) emissions were measured during core making activities associated with the use of a phenolic urethane binder system in the Technikon research and development core production facility. All of the core-making measurements were conducted within enclosures meeting the criteria for a temporary total enclosure according to US EPA Method 204.

Mixing

The mixing HAP emissions mainly consisted of phenol and formaldehyde. The HC as Hexane results for mixing contributed approximately 2% of the total found during these three test segments.

Gas/Purge and Fugitives

The HC as hexane results for gas/purge and fugitive emissions contributed approximately 80% of the total found during these three test segments.

Storage

The storage segment contributed 18% of the total found during these three test segments.

APPENDIX A APPROVED TEST PLAN AND SAMPLE PLAN

THIS PAGE INTENTIONALLY LEFT BLANK

TECHNIKON TEST PLAN

CONTRACT NUMBER: 1409 **TASK NUMBER:** 1.2.3

WORK ORDER NUMBER: 1165 **SERIES:** EQ

SAMPLE EVENTS: EQ001-009 mix, EQ021-029 make, EQ031-039 store

SITE: ___PRE-PRODUCTION (243) _X__ FOUNDRY(238)

TEST TYPE: Capability, core mixing, core making, core storage baseline 2002

METAL TYPE: None

MOLD TYPE: None

NUMBER OF MOLDS: NonE

CORE TYPE: AFS Step Core, Ashland Isocure ® LF305/52-904GR Phenolic urethane binder, TEA catalyzed

TEST DATE: **START:** 19 Aug 2002

FINISHED: 13 Sep 2002

TEST OBJECTIVES:

1. Develop facility and methods to make a core mix, make, and store baseline having significantly reduced process variability and improved independent sample capture methods.

2. Measure selective HAP and VOC emissions from Core sand mixing, Gas & Purge and Fugitive Core Making, and Core Storage of AFS step cores made with 1.75% Ashland binder to make a 2002 Core baseline.

VARIABLES:

1. Core sand mixing: The uncoated sand shall be Wexford W450 Lakesand. It shall be preheated or cooled to maintain a temperature of 85 +/- 5 degrees Fahrenheit. The binder shall be 1.75 +/- .0175% Ashland 305/52-904 mixed Part I/Part II in the ratio of 55/45. The sand will be coated in the Redford/Carver 50 pound core sand mixer for 7 minutes. One minute shall be used to dispense the sand and the two binder components and one additional minute shall be used strictly for discharging the muller. Each core sand mixing test shall be one seven (7) minute 50-pound cycle within the muller only monitored continuously by TGOC and adsorption tube sampling. Prior to the first test five (5) batches shall be run to the storage hopper to normalize the background. Sampling media will be changed after each one-cycle test, during which time mixing will continue in order to maintain the background concentration. A total of nine (9) mixing tests shall be run.

2. Core Making: The Redford/Carver core machine will operate on a nominal one (1) minute door-to-door cycle. The environmental enclosure shall be supplied with air controlled to 82 +/- 5 degrees Fahrenheit. TEA will be fed to the core machine at a nominal 5 grams per cycle. The purge pressure shall be 20+/-2 psi. The core-make test will begin after the

core machine has run sufficient time, at rate, to have the background emission concentration stabilize. Each core-make test will be 30 core cycles, about one half hour long, with continuous TGOC and adsorption tube sampling. Sample media will be changed after each 30-cycle test. The core machine will run continuously during media change and testing to maintain the background concentration. The gas & purge and fugitive emissions will be collected to a common sampling stack.

3. Core Storage: The store test will consist of weighed cores sampled four (4) at a time, from the core machine and placed in individual sampling domes. The domes are in a temperature-controlled room at 82+/- 5 degrees Fahrenheit and sampled continuously with TGOC and adsorption tubes for 5 hours.

BRIEF OVERVIEW: Core making is not a single process but rather a series of steps, each with its own process collectable and fugitive emissions. This test will look at selected HAP & VOC emissions from combined process collectable and fugitive emission streams during each of the core sand mixing, core making, and core storage steps.

SPECIAL CONDITIONS: The sand mixer will have a removable lid that allows air to infiltrate radially from the perimeter. Materials will be charged though a closeable door in the lid. Samples will be extracted from the center of the headspace below the lid. The core machine with step core tooling shall be housed in a double walled emission enclosure. The area between the walls shall be flushed with temperature-controlled air at 80+/-5 degrees Fahrenheit. This air shall be the ambient make up air for the core process within the enclosure. The core box and core machine shall be tightly plumbed to extract gasses passed through the core box into a common sampling stack with the fugitive gasses. The sampling environment will be maintained at 75-85°F.

Series EQ (Baseline)

Core Sand Mixing, Curing, and Storage

A. The Experiment:

1. Design and develop improved capability to evaluate the standard emissions from the mixing, making, and storage of gas catalyzed cold reacting core sand mixtures.
2. Evaluate the emissions from Ashland ISOCURE® LF305/52-904 part I and part II binder system to form a mixing, making, storage baseline for Iron-Phenolic Urethane binder systems.

B. Capability Study:

1. Mixing: Design and manufacture a capture hood for the Carver 50 pound capacity core sand mixer consisting of:

   a. An annular air makeup port which allows air to enter the mixer radially in such a way as to not significantly affect the emission evaporation from the sand surface.
   b. The ventilation rate shall be sufficient to prevent escape of the emissions except to the emission-sampling stream.
   c. An emission sampling port centered on the capture hood.
   d. A discharge pipe connected to a sampling train and pump via a heated line to the THC analyzer.

2. Core Making: Design and manufacture a total emission enclosure to capture and sample aggregate emissions from both the core box gas-purge cycles and fugitives from the enclosure.

   a. A gassing head capable of independently delivering a catalyzing gas and purge air from the external Luber gas generator to the common fugitives collection pipe. The flow rate in the sampling pipe at the sampling location must be virtually independent of the whether the gas-purge cycle is active.

3. Storage: Design and manufacture a set of four-storage emission sampling chambers.

   a. Each chamber shall have independent air flow controls.
   b. The sum of the chamber flows shall not exceed 50 liters/minute.
   c. One chamber shall be connected to the THC analyzer.
   d. Three chambers shall be connected to a sampling train via independent sampling media.

4. Conduct a set of preliminary tests to verify that the design criteria are met.

a. Conduct a "mixedness" test to verify that the mixer will create a homogeneous mixture within the prescribed mixing time.
b. Conduct a THC mixing calibration run according to the mixing schedule described below in order to determine the required media flow rates.
c. Conduct a THC core making calibration at 60 core /hour in order to determine the required media flow rates.
d. Conduct a THC core storage calibration run using core made per the core make procedure in order to determine the required media flow rates.
e. Record the ambient air temperature, pressure, and moisture content; scavenging air velocity; all machine parameters; all core weights; and all events.

C. Mixing Test: Nine discrete seven (7) minute batches run contiguously.

1. The test shall be conducted in the 50-pound Carver core sand mixer fitted with the capture hood with make-up air ventilation.

a. The emission sample shall be taken from the air space above the mixing sand.

2. Mixing

a. Turn on the Kloster sand heater/cooler. Adjust the set point so that sand is delivered to the mixer in the temperature range of 80-90°F.
b. Attach the emission sampling equipment to the 50-pound Carver core sand mixer.
c. Pre-measure 1.75% (BOS) Ashland ISOCURE® binder based on a 50 pound batch.

1) Part I (LF305) is 55% of the total resin and is 218.3 grams.
2) Part II (52-904) is 45% of the total resin and is 178.6 grams

Note: pre-wet the dispensing cup and tare the wet cup.

d. Pre-Weigh 50 pounds of Wexford W450 Lake Sand, heated to 80-90°F in the Kloster sand heater/cooler, in the Simpson Technologies weight system.
e. Place the capture hood on top of the mixer. Start the mixer.
f. Start the timer. Start monitoring with the THC only. Monitor with the THC continuously until the end of the test.
g. Make five (5) emission background-generating batches.
h. The procedure for this and the contiguously run test batches shall be as follows: Add the 50 pounds of raw sand, about 20-25 seconds, followed by the binder part I dispensed over 20 seconds, followed by binder part II dispensed over 20 seconds. All materials should be in the mixer within 50-70 seconds from start of the batch. Mix each batch until a total of 6 minutes have elapsed, then discharge the batch until a total of 7 minutes has elapsed from the start of the batch. Be prepared to recharge the mixer for the next batch immediately at the end of each 7-minute period.
i. During this activity the next set of components must be weighed and made ready. Having two or three material sets weighed and protected at all times makes the process go smoothly.

j. At the end of fifth batch (35 minutes)

1) Close the discharge door.
2) Open the sample train to the mixer.
3) The emission sample size will be one (1) batch.
4) During the next batch the media will be changed.
5) The next batch will be an emission sample again.
6) Continue alternating until nine (9) emission tests are complete.

k. Repeat steps C.2.g-h for as many cycles as is necessary to complete the five (5) background batches, the nine (9) emission test batches, and nine (9) media changing periods, a total of 23 batches. Continue batches uninterrupted during media changes between tests.

D. Core Making test: Nine (9) tests each having thirty (30) approximately one (1) minute core cycles.

1. Turn on the core storage room temperature control system 24 hours ahead of expected use time. Set control so that the core machine sees 80°F.
2. Turn on and adjust the Luber TEA gas generator.

a. Make sure there is enough TEA in the Luber TEA storage tank.
b. Set the MAX WORKING PRESSURE to 45 psi.
c. Set the gassing time (T1) to 0.75 seconds
d. Adjust the TEA flow rate to .019 pounds/second.

Note: This will give an amine input of 5.1 grams per cycle.

e. Leave the Timer TR1 at 0.3 seconds, the proportional valve voltage at 7.5 volts and timer at 3 seconds, the low purge pressure at 10 psi and high purge pressure at 45 psi.

Note: This should yield a working pressure of about 7 psi.

f. Connect the TEA weighing container to the Luber supply line.

1) Dispense about 250 grams of TEA into the weigh container. The scale has a 300-gram capacity.
2) Isolate the Luber TEA storage tank.

g. Conduct 5 gassing purge cycles within ½ hour of testing to stabilize the Luber generator.

1) Vent this material to the scrubber.
2) Record the TEA weight dispensed.

h. Record the ambient temperature, the inlet pressure, Max working pressure, working pressure, TEA flow rate, gassing timer value, & purge timer value.

3. Attach the emission sample train to the gas-purge-fugitive sample pipe.
4. Begin monitoring with the THC.
5. Prepare the core sand in the Carver mixer according to section C.2.g-h except without the emission sampling equipment attached to the mixer.
6. Prepare the core machine emission enclosure.
7. Verify that the temperature controlled core test room is set to deliver air at 75-85°F to the core enclosure.
8. Set up the Redford/Carver core machine with the step core corebox.
9. Verify that the air temperature in the gas-purge-fugitive exhaust tube is 75-85 degrees Fahrenheit.
10. Set the Redford/Carver core machine to gas for 0.75 seconds with zero (0) second delay after gassing and twenty (20) second purge. Total cycle time to be one (1) minute. Set the cycle counter to zero (0).
11. Start and calibrate the Luber TEA vaporizer to dispense 5.0-5.2 grams of TEA per machine cycle.
12. Mix core sand per section C.2.g-h, as required, in fifty (50) pound batches to assure continuity of production.
13. Cycle the core machine for 10-15 cycles or until fugitives emissions are stable based on the THC and good core manufacture is achieved. Note: if release agent is required brush release agent on to core box do not spray.
14. Make cores continuously as above. Any stoppage will impact the fugitives emission level.
15. Record the number and weight of each core throughout the test.
16. When everybody is ready, start the emission-sampling clock and open the sample train. Sample continuously for 30 core cycles, approximately thirty (30) minute, then close the sample train.
17. Do not stop making core.
18. Set up the sample train again and repeat the test for another thirty-core test. A total of nine (9) half-hour tests are to be performed.
19. Empty and clean the core machine and core sand mixer.

E. Core storage tests.

1. Prepare the 4 individual core storage emission enclosures.
2. Set up a THC to monitor one enclosure and the sample train to monitor the other three enclosures and calibrate them.
3. Mix sand by the method of section C.2.g-h.
4. Make core by the method of Section D.
5. Number, weigh, and record each core.
6. When good core are being made sample four (4) cores whose weight is 7.30, 7.35, or 7.40 pounds for the storage test. Place these cores in the core storage emission enclosures.

7. Close the enclosure bonnet, start the test clock, open to the THC or the sample train.
8. Record the start time for each core as well as the core weight
9. Continue sampling train for 5 hours then close the sample train. Separate longer tests may be conducted by this procedure at the discretion of the emission team.
10. Continue the THC monitoring for 24 hours.
11. Repeat this procedure to obtain nine (9) discrete tests plus the THC monitoring.

Executive Summary

This report contains the results of testing conducted at the Technikon/CERP Pre-Production Foundry to establish a tap water reference against which the effects of advanced oxidant (AO) enriched water on the emissions from vented cored greensand molds may be investigated. Casting surface quality was not evaluated during these tests. This report provides results from a total of nine test plans (tests), with the first three tests performed to condition virgin sand and mold materials. Results are presented for all nine tests, and separately for the six post-conditioning tests. The approved test plan for this test series may be found in Appendix A of this document. Points of comparison between this and related AO studies have been **bolded**.

This report contains the results of emission testing at the Casting Emission Reduction Program (CERP) Pre-Production Foundry operated by Technikon LLC. The specific objective of Test Plan DQ was to determine the emission reductions, if any, of organic Hazardous Air Pollutants (HAPs) and Volatile Organic Compounds (VOCs) for a vented **tap water** tempered virgin greensand mold utilizing a **20/80** Western to Southern bentonite clay ratio and Seacoal. The core package consisted of organic free sodium silicate cores so that the only known mold organic was Seacoal. The test results may be compared to Pre-Production Tests DR, and DT that also utilize a vented **tap water** tempered virgin greensand mold with Seacoal, and bentonite clay ratios of **50/50** and **80/20** Western to Southern respectively. In addition, test results may be compared to Pre-Production Tests DA, DS, and DU that are duplicates of DQ, DR, and DT, except that they utilize **advanced oxidation (AO) treated water** additions instead of tap water.

The Pre-production Foundry is a simple general purpose manual foundry that was adapted and instrumented to make detailed organic emission measurements, using methods based on EPA protocols for pouring, casting cooling, and shakeout processes on discrete mold and core packages. The measurements are conducted under tightly controlled conditions not feasible in a commercial foundry. It is the initial step in the schema of evaluating a new product or process for the foundry industry. The results of testing in the Pre-production Foundry are evaluated to determine whether further testing in the Technikon Production Foundry is warranted.

The testing performed involved the collection of continuous air samples over a seventy-five minute period, including the mold pouring, cooling, shakeout, and post shakeout periods. Process and stack parameters were measured and include: the weights of the casting, mold, core binder, and core; Loss on Ignition (LOI) values for the mold prior to the test and at shakeout; percent clays; metallurgical data; and stack temperature, pressure, volumetric flow rate and moisture content. The process parameters were maintained within prescribed ranges in order to ensure the reproducibility of the tests. Nine (9) individual sampling events were conducted for test plan DQ. Three tests were utilized to condition the sand to the tap water, based on historical data, and six tests were utilized for the actual test.

Samples were collected and analyzed for a limited list of twenty (20) target compounds using procedures based on US EPA Method 18. Continuous monitoring of the Total Gaseous Organic Concentration (TGOC), formerly Total Hydrocarbon Content (THC), of the emissions was conducted according to US EPA Method 25A. Finally, the "condensable" organic material in the

emissions was determined using a Technikon developed procedure. The "condensables" represent the "back half" catch from US EPA Method 5.

The mass emission rate of each parameter or target compound was calculated, in pounds per ton of metal, using the Method 25A data or the laboratory analytical results, the measured source data, and the weight of each casting. Results for structural isomers have been grouped and reported as a single entity. For example, ortho-, meta-, and para-xylene are the three (3) structural isomers of dimethyl benzene. Several "emissions indicators," in addition to the TGOC (THC) as Propane, were also calculated. The HC as Hexane results represent the sum of all organic compounds detected and expressed as Hexane. All of the following sums are sub-groups of this measure. The "Sum of VOCs" is based on the sum of the individual target VOCs measured and includes the HAPs and Polycyclic Organic Material (POMs) listed in the Clean Air Act Amendments of 1990. The "Sum of HAPs" is the sum of the individual target HAPs measured and includes the POMs. Finally, the "Sum of POMs" is the sum of all of the polycyclic organic material measured. Results for the emission indicators, for all nine-test runs, and for the six post-conditioning test runs, are shown in the following table. All results are measured as pounds emitted per ton of metal.

Number of Tests Included	**TGOC (THC) As Propane**	**HC as Hexane**	**Sum of VOCs**	**Sum of HAPs**	Sum of POMs
6	2.136	0.6072	0.2093	0.1881	ND
9	2.459	0.6435	0.2356	0.2127	ND

Due to the fact that the results expressed here are sums derived from a set of approximately 20 analytes, they are comparable only to test series utilizing an equivalent analyte list. All test series performed for the AO water/Tap water, clay ratio studies will utilize this analyte list, and are therefore comparable. But they cannot be compared to similarly titled results from test series in which an analytes list of greater than 70 compounds have been used to generate the data.

In addition, it must be noted that the reference and product testing performed is not suitable for use as general emission factors or for purposes other than evaluating the relative emission reductions associated with the use of alternative materials, equipment, or processes. The emissions measurements are unique to the specific castings produced, materials used, and testing methodology associated with these tests, and should not be used as the basis for estimating emissions from actual commercial foundry applications.

1.0 Introduction

1.1 Background

Technikon LLC is a privately held contract research organization located in McClellan, California, a suburb of Sacramento. Technikon offers emissions and process research services to industrial and government clients specializing in the metal casting and mobile emissions areas. Technikon also operates the Casting Emission Reduction Program (CERP). CERP is a cooperative initiative between the Department of Defense (US Army) and the United States Council for Automotive Research (USCAR). Its purpose is to evaluate alternative casting materials and processes that are designed to reduce air emissions and/or produce more efficient casting processes. Other technical partners directly supporting the project include: the American Foundry Society (AFS); the Casting Industry Suppliers Association (CISA); the US Environmental Protection Agency (USEPA); and the California Air Resources Board (CARB). Each of these partners is represented on a Steering Committee (as voting or non-voting members) that has oversight for the CRADA testing conducted at the Technikon facility.

1.2 CERP Objectives

The primary objective of CERP program is to evaluate materials, equipment, and processes used in the production of metal castings. The Technikon facility was designed to evaluate alternate materials and production processes designed to achieve significant air emission reductions, especially for the 1990 Clean Air Act Amendment organic Hazardous Air Pollutants (HAP). The facility has two principal testing arenas: a Pre-production Foundry designed to measure airborne emissions from individually poured molds, and a Production Foundry designed to measure air emissions in a continuous full scale production process. Each of these testing arenas has been specially designed to facilitate the collection and evaluation of airborne emissions and associated process data. The data collected during the various testing projects are evaluated to determine both the airborne emissions impact of the materials and/or process changes, and their stability and impact upon the quality and economics of casting and core manufacture. The materials, equipment, and processes may need to be further adapted and defined so that they will integrate into current casting facilities smoothly and with minimum capital expenditure.

Normally, Pre-production testing is conducted first in order to evaluate the air emissions impact of a proposed alternative material, equipment, or process in the most cost effective manner. The Pre-production Foundry is a simple general purpose manual foundry that was adapted and instrumented to make detailed emission measurements using methods based on EPA protocols for pouring, casting cooling, and shakeout processes on discrete mold and core packages under tightly controlled conditions not feasible in a commercial foundry. The Pre-production Foundry uses an eight-cavity, bottom feed AFS step block as its test mold pattern.

The Production Foundry's design as a basic greensand foundry was deliberately chosen so that whatever is tested in this facility will also be convertible to existing mechanized commercial foundries. The type and size of equipment, materials, and processes used emulate an automotive foundry. This facility is used to evaluate materials, equipment, and processes in a continuous process that is allowed to vary to the limits of commercial experience in a controlled manner.

The Production Foundry provides simultaneous detailed individual emission measurements using methods based on USEPA protocols of the melting, pouring, sand preparation, mold making, and core making processes. It is instrumented so that the data on all activities of the metal casting process can be simultaneously and continuously collected, in order to completely evaluate the economic impact of the prospective emission reducing strategy. The Production Foundry's test casting is a single cavity Ford Motor Company I-4 engine block. Castings are randomly selected to evaluate the impact of the material, equipment, or process on casting quality. Alternative materials, equipment, and processes that demonstrate significant air emission reduction potential, preserve casting quality parameters, and that are economically viable based on the Pre-production testing, may be further evaluated in the Production Foundry.

It must be noted that the results from the reference and product testing performed are not suitable for use as general emission factors or for other purposes other than evaluating the relative emission reductions associated with the use of alternative materials, equipment, or manufacturing processes. The emissions measurements are unique to the specific castings produced, materials used, and testing methodology associated with these tests.

1.3 Report Organization

This report has been designed to document the methodology and results of a specific test plan that was used to evaluate the performance of an alternative material, equipment, or process in the Pre-production Foundry. Section 2 of this report includes a summary of the methodologies used for data collection and analysis, emission calculations, QA/QC procedures, and data management and reduction methods. Specific data collected in support of these tests are summarized in Section 3 of this report, with detailed data included in Appendices B and C of this report. Section 4 of this report contains a discussion of the results along with conclusions and recommendations.

The raw data for this test series are included in a data binder that is maintained at the Technikon facility. There are several support documents that provide details regarding the testing and analytical procedures used. Appendix F contains a listing of these support documents.

1.4 Preliminary Testing

The foundation for the specific test protocols and airborne emission measurements have been determined from testing performed to:

?? Establish the required number of samples needed to statistically support the evaluation of emission reduction potentials of the alternative materials, equipment, and processes that may be evaluated;

?? Provide a series of standardized emissions from standard mold and core packages.

It has been determined that nine replicate tests will provide a statistically significant sample for the purposes of evaluating the emission reductions from alternative materials, equipment, and processes. The results of the testing conducted in support of this conclusion is included in a report entitled Evaluation of the Required Number of Replicate Tests to Provide Statistically

Significant Air Emission Reduction Comparisons for the CERP Pre-production Foundry Test Program.

Appendix A of this report contains the Test Plan for Test Series DQ.

Appendix B of this report contains detailed test results for Test Series DQ.

1.5 Specific Test Plan and Objectives

This report contains the results of testing performed to assess the emission reductions, if any, of organic Hazardous Air Pollutants (HAPs) and Volatile Organic Compounds (VOCs) for a tap water treated virgin greensand mold utilizing a 20/80 Western to Southern bentonite clay ratio and Seacoal. The core package consists of organic free sodium silicate cores so that the only known mold organic is Seacoal.

The results from test DQ will provide comparative data to Pre-production Tests DR and DT, which are also tap water tempered greensand molds with Seacoal, but with bentonite clay ratios of 50:50 and 80:20 Western to Southern, respectively. Test DQ will also provide a tap water reference for comparison to three additional Test Series, DA, DS, and DU, where advanced oxidation (AO) treated water additions were substituted for tap water in molds containing each of the three clay ratios listed above.

Table 1-1 provides a summary of the Test Plan. The detail of the approved test plan is included in Appendix A.

Table 1–1 Test Plan Summary

	Test Plan
Type of Process tested	20/80 Western to Southern Clays w/ Tap Water
Test Plan Number	RE 1 00112 DQ
Mold Type	Hand Rammed Greensand
Core Type	Organic Free Sodium Silicate
Casting Type	Eight-cavity bottom feed AFS step block
Baseline Comparison	Greensand
Number of molds poured	6 (9 including conditioning runs)
Test Dates	12/13/00, 12/14/00, 12/18/00
Emissions Measured	20 organic HAPs and VOCs
Process Parameters Measured	Total Casting, Mold and Core Weights, Metallurgical data, Mold and Core Component Weights, % LOI (mold and core), % Clay, Stack Temperature, Stack Moisture Content, Stack Pressure, and Stack Volumetric Flow Rate

2.0 Test Methodology

2.1 Description of Process and Testing Equipment

The following figure is a diagram of the Pre-production Foundry process equipment.

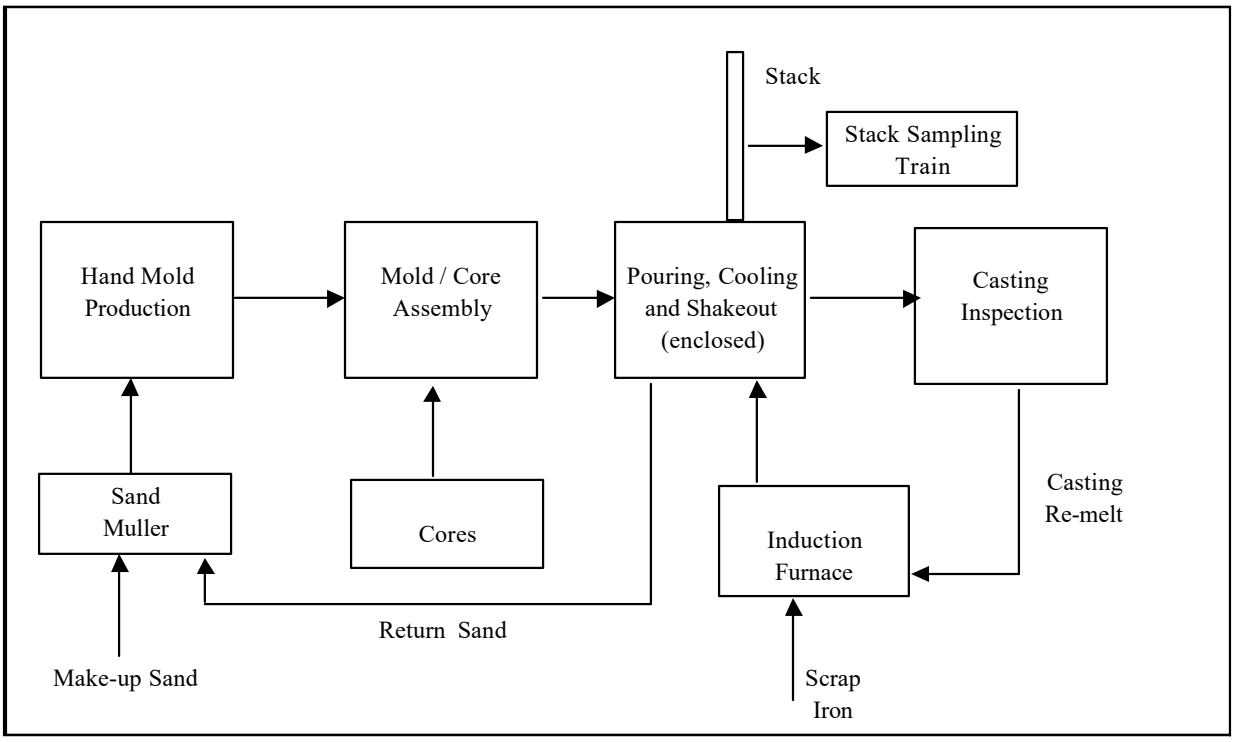

Figure 2-1 Pre-production Foundry Layout Diagram

2.2 Description of Testing Program

The specific steps used in this sampling program are summarized below:

1. **Test Plan Review and Approval:** The proposed test plan was reviewed by the Technikon staff and CTC Program Manager, and approved.

2. **Mold, Core and Metal Preparation:** The molds and cores are prepared to a standard composition by the CERP production team. The cores are made either by hand (if sodium silicate) or blown by a Redford core blower, and relevant process data are collected. If new core processes are being tested, the cores are placed in new lake sand/clay/water molds. If new mold binder systems or processes are being evaluated, organic free sodium silicate step cores are placed into the molds. Iron is melted in a 1000 lb. Ajax induction furnace (Model MFB-1000). The amount of metal melted is determined from the poured weight of the casting and the number of molds to be poured. The metal composition is prescribed by a

metal composition worksheet. The weight of metal poured into each mold is recorded on the process data summary sheet.

Setting of Step Cores in Mold

3. **Individual Sampling Events:** Replicate tests are performed on nine mold/core packages. The mold/core packages are placed into an enclosed test stand. Iron is poured through an opening in the top of the enclosure. The opening is closed as soon as pouring is completed. Continuous air samples are collected during the forty-five minute pouring and cooling process, during the fifteen minute shakeout of the mold, and for an additional fifteen minute period following shakeout. The total sampling time is seventy-five minutes.

Pouring of Step Core Molds Through Opening in Collection Hood

The finished castings are cleaned and quality checks of the castings are performed. Additional tests may be required for new mold materials with the molding sand being recycled into new molds to evaluate the long-term effects on molding sand properties.

The weights of the molds, cores, Seacoal additions, and binder are recorded for each mold on the Process Data Summary Sheet. In addition, the pouring temperature, number of cavities poured, the %LOI and the % clays of the mold before pouring and at shakeout, and the % LOI of the core are recorded on the Process Data Summary Sheet.

The unheated emission hood is ventilated at approximately 700 SCFM through a 12-inch diameter heated duct. Emissions samples are drawn from a sampling port located to ensure conformance with EPA Method 1. The tip of the probe is located in the centroid of the duct. The samples are collected at a constant rate in adsorption tubes (test sample and duplicate sample).

Castings on the Shake Out Deck

4. **Process Parameter Measurements:** Table 2-1 lists the process parameters that are monitored during each test. The analytical equipment and methods used are also listed.

Table 2-1 Process Parameters Measured

Parameter	Analytical Equipment and Methods
Core Weight	Mettler PJ8000 Digital Scale (Gravimetric)
Mold Weight	Acme 4260 Crane Scale (Gravimetric)
Casting Weight	Westweigh PP2847 Platform Scale (Gravimetric)
Seacoal Weight	Toledo PAC-DPC-606050 balance (Gravimetric)
Binder Weight	Mettler PJ8000 Digital Scale (Gravimetric)
Volatiles	Mettler Pb302 Scale (AFS procedure 212-87-S)
LOI, % at mold and shakeout	Denver Instruments XE-100 Analytical Scale (AFS procedure 212-87-S)
Core LOI, %	Denver Instruments XE-100 Analytical Scale (AFS procedure 321-87-S)
Clay, % at mold and shakeout	Dietert 535A MB Clay Tester (AFS Procedure 210-89-S)
Metallurgical Parameters	
Pouring Temperature	Electro-Nite DT 260 (T/C immersion pyrometer)
Carbon/Silicon Fusion Temperature	Electro-Nite Datacast 2000 (Thermal Arrest)
Alloy Weights	Ohaus MP@
Mold Compactability	Dietert 319A Sand Squeezer (AFS procedure 221-87-S)
Carbon/Silicon	Baird Foundry Mate Optical Emissions Spectrometer

5. **Emissions Measurement:** The specific sampling and analytical methods used in the Pre-production Foundry tests are based on the USEPA reference methods shown in Table 2-2. The details of the specific testing procedures and their variance from the reference methods are included in the Emissions Testing and Analytical Testing Standard Operating Procedures.

Table 2-2 Sampling and Analytical Methods

Measurement Parameter	Test Method
Port location	EPA Method 1
Number of traverse points	EPA Method 1
Gas velocity and temperature	EPA Method 2
Gas density and molecular weight	EPA Method 3a
Gas moisture	EPA Method 4, gravimetric
HAPs concentration	EPA Method 18, TO11, NIOSH 2002*
VOCs analysis	EPA Method 18, 25A, TO11, NIOSH 2002*
Condensables	Technikon developed method**

*These methods were specifically modified to meet the testing objectives of the CERP Program.
**The Technikon condensables method is intended to provide a measure of the EPA Method 5 "back-half" determination.

6. **Data Reduction, Tabulation and Preliminary Report Preparation:** The analytical results of the emissions tests provide the mass of each analyte in the sample. The total mass of the analyte emitted is calculated by multiplying the mass of analyte in the sample times the ratio of total stack gas volume to sample volume. The total stack gas volume is calculated from the measured stack gas velocity and duct diameter, and corrected to dry standard conditions using the measured stack pressures, temperatures, gas molecular weight, and moisture content. The total mass of analyte is then divided by the weight of the casting poured to provide emissions data in pounds of analyte per ton of metal.

   The results for each sampling event are included in Appendix B of this report. The results for each test are also averaged and are shown in Table 3-1.

7. **Report Preparation and Review:** The Preliminary Draft Report is reviewed by the Process Team and Emissions Team to ensure its completeness, consistency with the test plan, and adherence to the prescribed QA/QC procedures. Appropriate observations, conclusions and recommendations are added to the report to produce a Draft Report. The Draft Report is reviewed by the Vice President-Measurement Technologies, the Vice President-Operations, and the Technikon President. Comments are incorporated into a Final Report that is circulated for signatures and then distributed.

2.3 Quality Assurance and Quality Control (QA/QC) Procedures

Detailed QA/QC and data validation procedures for the process parameters, stack measurements, and laboratory analytical procedures are included in the CERP Standard Operating Procedures. In order to ensure the timely review of critical quality control parameters, the following procedures are followed:

- Immediately following the individual sampling events performed for each test, specific process parameters are reviewed by the Manager - Process Engineering to ensure that the parameters are maintained within the prescribed control ranges. Where data are not within the prescribed ranges, the Manager - Process Engineering and the Vice President-Operations determine whether the individual test samples should be invalidated or flagged for further analysis following review of the laboratory data.

- The source (stack) and sampling parameters, analytical results and corresponding laboratory QA/QC data are reviewed by the Emissions Measurement Team to confirm the validity of the data. The VP-Measurement Technologies reviews and approves the recommendation, if any, that individual sample data should be invalidated. Invalidated data are not used in subsequent calculations.

3.0 Test Results

The average emission result, in pounds per ton of metal poured, is presented in Table 3-1 for tests reported in this document. This table includes all the individual organic HAP compounds that comprise the reduced analyte list for this test series, along with the corresponding sum of VOCs, sum of HAPs, and sum of POMs. The table also includes the TGOC (THC) as Propane and HC as Hexane. Figures 3-1a through 3-1f present the five emissions indicators and individual HAP emissions data from Tables 3-1 in graphical form. Appendix B contains the detailed data including the results for all analytes measured. Table 3-2 includes the averages of the key process and source parameters and the data target ranges. All emission results are presented without blank or background correction. Detailed process and source data are presented in Appendix C.

Method 25A charts for the tests are included in Appendix D of this report. The charts are presented to show the VOC profile of emissions for each pour.

The log used during validation of the laboratory data is maintained in the Technikon offices.

Table 3-1 Test Series DQ Summary of Individual Test Results – Lbs/Ton of Metal

COMPOUND / SAMPLE NUMBER	Six Mold Average (Lb/tn)	Nine Mold Average (Lb/tn)
TGOC (THC) as Propane	2.136	2.459
HC as Hexane	0.6072	0.6435
Sum of VOCs	0.2093	0.2356
Sum of HAPs	0.1881	0.2127
Sum of POMs	ND	ND
Individual Organic HAPs		
Benzene	0.0891	0.1051
Toluene	0.0503	0.0547
Xylene (Total)	0.0371	0.0403
Ethylbenzene	0.0061	0.0068
Acetaldehyde	0.0055	0.0059
1-Methylnaphthalene	NA	NA

Avg. Stack Pressure, in. Hg	30.21	29.92 ± 1
Stack Flow Rate, scfm	692	700 ± 50

4.0 Discussion of Results

A selected analyte list was utilized in the analysis of stack emissions from Test Series DQ. The results for the sum of HAPs, VOCs, and POMs that are derived from this list can therefore only be compared to other test series that also utilize this reduced list. The sampling and analytical methodologies were the same for Tests DQ, DA, DR, DS, DT, and DU, so comparison of these six test series will allow the effects of advanced oxidation treatment to be evaluated against tap water for three different ratios of western/southern bentonite clays, 20/80, 50/50, and 80/20.

Two methods were employed to measure undifferentiated hydrocarbon emissions, TGOC (THC) as propane, performed in accordance with EPA Method 25A, and HC as hexane. EPA Method 25A, TGOC (as propane), is weighted to the detection of more volatile hydrocarbon species, beginning at C1 (methane), with results calibrated against a three-carbon alkane (propane). HC as hexane is weighted to detection of relatively less volatile compounds. This method detects hydrocarbon compounds in the alkane range between C6 and C16, with results calibrated against a six-carbon alkane (hexane).

TGOC results for the six post-conditioning molds exceeded HC as Hexane by a factor of approximately 3.5. When the three conditioning molds are added to the average results for these two analyses, TGOC exceeds HC as Hexane by a factor of almost 4. Average TGOC results decreased by 13% when only post-conditioning molds are considered, while HC as hexane results decreased by 5.5%.

Phenol and aniline were included in the selected analyte list, but results have not been incorporated due to sampling difficulties for the NIOSH 2002 method. Results for these analytes will be included in the comparative tests listed in the first paragraph.

Observation of measured process parameters indicates that the tests were run within an acceptable range.

THIS PAGE INTENTIONALLY BLANK

APPENDIX A APPROVED TEST PLAN FOR TEST SERIES DQ

THIS PAGE INTENTIONALLY BLANK

CERP TEST PLAN

> **CONTRACT NUMBER:** 1256 **TASK NUMBER:** 130

> **CONTROL NUMBER:** RE 1 00112

> **SAMPLE FAMILY:** DQ

> **SAMPLE EVENTS:** 001 thru 009

> **SITE:** X **PRE-PRODUCTION (243)** **CERP FOUNDRY (238)**

> **TEST TYPE:** Clay Ratio Study, using Tap Water Reference

> **MOLD TYPE:** Greensand, 20/80: Western/Southern Bentonite ratio with Seacoal and using Tap Water

> **NUMBER OF MOLDS:** 9

> **CORE TYPE**: Sodium Silicate Step Block Cores

> **TEST DATE:** **START:** 13 Dec 00

FINISH: 18 Dec 00

TEST OBJECTIVES:

Primary: To determine the effects on HAP emissions from a tap water tempered southern bentonite rich sodium silicate cored greensand mold containing Seacoal as the only known organic source and compare those emissions to test series DR (tap water, silicate core, 50/50 western/southern bentonite), DT (tap water, silicate core, 80/20 western/southern bentonite), DA (A/O water, silicate core, 20/80 western/southern bentonite), DS (A/O water, silicate core, 50/50 western/southern bentonite), and DU (A/O water, silicate core, 80/20 western/southern bentonite). This group of tests is a follow up on test DA made with virgin materials run as a single batch turns test. Series DQ will be monitored by the total hydrocarbon analyzer, sample tubes, bags, and condensate trap.

VARIABLES: Sand composition shall be maintained at 7.0 +/- 0.5 % MB clay, 5.0 +/- 0.3 % LOI using Hill & Griffith supplied clay and Seacoal. The Western Bentonite /Southern Bentonite ratio shall be 20/80. Sodium silicate step cores will be made using Wedron 420 Silica sand and 5.0 % J.B. DeVeene Kleencast #1 binder, gassed with CO_2 and dried at 250° F for two hours. The statistical validity of the test will be based on nine sampling events (molds).

BRIEF OVERVIEW: This test along with companion tests DR, DT, DA, DS, & DU is intended to determine how silicate cored green sand with 80/20, 50/50 & 20/80 western/southern bentonite ratios respond to both tap water and A/O water treatment. The bentonite content and LOI will initially be adjusted to 7.0% +/- 0.5% and 5.0% +/- 0.3% respectively. Subsequent molds will be made on a single mold "turns" basis with the bond replacement rate based on current sand lab data to maintain the clay & LOI contents within the above ranges. DQ molds will be made only after the process lab determinations or projections are complete.

SPECIAL CONDITIONS: Only tap water shall be used. The total hydrocarbon analyzer, tube samples, & condensate trap shall be used to gather and conduct emission tests on the sand to form the (9) mold test. Process effects on sand physical and mechanical properties shall be tracked**.**

Project Manager (CTC)	4/25/01 Date

Series DQ

Pre-production process instructions

A. Experiment: A study to compare the impact of tap water on molds with the Western/Southern Bentonite ratio of 1:4. The mold will be made from virgin green sand mold materials consisting of Seacoal; bentonite in the ratio of 1:4; tempered with tap water; poured at constant weight, surface area, sodium silicate core weight, and shape factor, a single batch turns test. This test is to be compared to reference tests DR, & DT, and comparative tests DA, DS, & DU.

1. Mold sand: Virgin mix of Wexford W450 lake sand, Okie 90 silica sand, western and southern Bentonites in ratio of 1:4, Seacoal, and tap water per recipe.

2. Core: Step core made with Wedron 420 silica sand and 5% J.B. DeVeene Kleencast #1® sodium silicate core binder, gassed with CO_2.

3. Metal: Class 30-35 gray cast iron poured at 2630°F.

Caution
Observe all safety precautions attendant to these operations as delineated in the Pre-production operating and safety instruction manual.

4. The following test shall be conducted:

a) Sand batch: Single sand batch to be used for all 9 DQ molds. All molds will be monitored in real time with the Airsense spectrometer and THC analyzer. Additionally sample tubes and condensables samples will be collected on each mold.

b) DQ001: Virgin mix as described above, vented mold, reference JB DeVeene Kleencast #1? cores, tap water.

c) DQ002-DQ009: The 20/80 western/southern bentonite comparative test; Re-mulled, reconstituted sand, tap water, vented mold, reference JB DeVeene Kleencast #1? cores.

B. Sodium silicate Core

1. Core sand mixing.

a) Clean the core sand mixer.

b) Add 50 pounds of Wedron 420 silica sand to the running mixer.

c) Slowly pour 2.5 +/- .03 pounds of Sodium silicate resin into the sand. Distribute the resin as it is poured. Avoid pouring the resin on the plows or walls of the mixer or in one location or resin balling will occur preventing proper mixing.

d) Mix for three minutes after the resin is all in.

e) One batch will make about 6 cores.

f) Once per hour catch a clean 50-100 gm sample of the raw sand for the sand lab to perform a core LOI test. Place the sample in a clean bag and label with date and time.

2. Making step cores.

a) Place the core box on a flat surface large open side up.

b) Place about 2 inches of sand in the bottom of the step section. Firmly tamp the sand into the 1inch diameter bottom using a ½ inch diameter rod.

c) Place a few more inches of sand in the core box and compact it. Take care to avoid parting planes. Repeat until the box is full.
d) Scrape off the excess. Remove the unused sand away from the gassing area.
e) Place a gassing plate on the open end of the core box.
f) Hold the plate down and gas the core for 20 seconds on each of the two gas holes with 20 psi CO2 gas.
g) Dry the cores for two hours at 250°F and allow to cool.
h) Bag the cores in moisture proof bags for storage.
i) Identify each bag by batch number.
j) Record the date, batch number, the batch mix time, sand batch weight, resin weight, the gassing time, the gas pressure, individual dried core weight, good core count from each batch.
k) The sand lab will determine the core LOI and the Resin Content LOI associated with each mold.

C. Sand preparation

1. Start up batch: make 1, DQ001.
a) Thoroughly clean the pre-production muller.
b) Weigh and add 1600 +/- 50 pounds total new Wexford W450 lake sand and Oklahoma 90 silica sand, per the recipe, to the running pre-production muller.
c) Add 5 pounds of tap water to the muller to suppress dust distributing it across the sand. Allow to mix for 1 minute.
d) Add the clays in proportion to the sand weight per the standardization mixture recipe for this test slowly to the muller to allow them to be distributed throughout the sand mass.
e) Dry mull for about 3 minutes to allow distribution and some grinding of the clays to occur.
f) Split the batch into approximately equal sized portions.
g) To each half-batch temper the sand-clay mixture slowly with tap water to allow for distribution.
h) After about 2 gallons of water have been added allow 30 seconds of mixing then start taking compactability test samples. Grab sufficient sample at each compactability test to fill a quart zip-lock bag. Label each bag and retain it.
i) Based on each test add water incrementally to adjust the temper. Allow 1 minute of mixing. Retest. Repeat until the compactability is in the range 45-51%.
j) Discharge the sand into the mold half.
k) Record the total sand mixed in the combined batch, the total of each type of clay added to the combined batch, the amount of water added to each half batch, the total mix time on each half batch, the final compactability and sand temperature at charge and discharge on each half batch, the time that the water was taken from its source, the time that each mold half was complete, the time the mold is delivered to the pour area, and the water type and temperature. Record the maximum muller current just prior to sand discharge.
l) The sand will be characterized for Methylene Blue Clay, Moisture content, Compactability, Green Compression strength, 1800°F loss on ignition (LOI), and

900°F volatiles. Each volatile and LOI test requires a separate 50-gram sample from the collected sand.

NOTE: The sand lab data must be available and approved by the process engineer before the mold is committed to pouring.

2. Re-mulling: make 8, DQ002-DQ009.
- **a)** Add all the sand from the previous mold to the muller including any sand previously mixed but not placed in the mold.
- **b)** Add 5 pounds of tap water to the muller to suppress dust distributing it across the sand. Allow to mix for 1 minute.
- **c)** Add the clays and coals per the re-bond recipe slowly to the muller to allow them to be distributed throughout the sand mass. Follow the above procedure beginning at C.1.e.
- **d)** The sand lab will sample the mold sand from each mold as it is being made and from the shaken out sand after it has been re-blended but before the additions are made. The three (3) "MOLD" samples will be taken from the initial muller discharge into the drag, from the last sand into the drag, and the last sand into the cope. The three (3) "SHAKEOUT" samples shall be taken from within the muller at three locations approximately 120 degrees apart. The sand will be tested for MB clay, compactability, and moisture content, green compression strength, 1800°F LOI, 900°F volatile. Each volatile and LOI test requires a separate 50-gram sample from the collected sand. Report results associated with the mold (test number, DQ0xx) from which it was taken.

NOTE: The sand lab data must be available from the blended shakeout sand and a recipe approved by the process engineer before the next mold is prepared. Additionally the sand lab data must be available and approved by the process engineer for the next mold's sand before the mold is committed to pouring.

NOTE: Once each day, at the time when the shakeout sand has been re-blended, the total sand shall be weighed and recorded. Extra sand shall be discarded to keep the batch weight at 1600 +/- 50 pounds.

D. Molding: Step block pattern.

1. Pattern preparation:
- **a)** Inspect and tighten all loose pattern and gating pieces.
- **b)** Repair any damaged pattern or gating parts.

2. Making the green sand mold.
- **a)** Lightly rub parting oil from a damp oil rag on the pattern particularly in the corners and recesses.

Caution: Do not pour gross amounts of parting oil on the pattern to be blown off with air. This practice will leave sufficient oil at the parting line to be adsorbed by the sand, weakening it, and the burning oil will be detected by the emission samplers.

b) Place 4 inches of loose sand on the pattern and ram all pockets and the perimeter tightly using only vertical strokes. Caution: non- vertical ramming strokes will move blocks of compacted sand leaving voids, which may cause the mold to fail. Do not ram all the sand to form a parting plane surface or the mold can fail. Add sand in increments of 4-6 inches of loose sand ramming tightly around the pattern.

c) When the rammed sand covers the pattern by 3 or more inches the sand can be rammed less tightly but still avoid lamination planes.

d) Level off the cope and drag mold surfaces opposite the pattern to minimize metal splatter and allow the mold to be fully supported.

e) Cut the pour basin smoothly to reduce the amount of sand prone to get washed down the sprue.

f) Remove the pattern, inspect and blow out the mold, and set the cores in the drag. Verify that the cores are fully set in their prints. The step cores will be flush with the parting line. If a piece of the mold is missing contact your supervision for a decision on the acceptability of the mold.

g) Vent the cope when required according to the test list above with ¼ vents according to the template.

h) Close the mold straight being careful not to crush anything.

i) Bolt the flask halves together and deliver the mold to the pouring area.

j) Weigh and record the closed unpoured mold, the core weigh, and the sand weight by difference.

E. Emission hood:

1. Loading.

a) Hoist the mold onto the shakeout deck within the emission hood.

b) Close, seal, and lock the emission hood

2. Shakeout.

a) After the cooling time prescribed in the emission test plan turn on the shakeout unit and run for the time prescribed in the emission test plan.

b) Turn off the shakeout, open the hood, remove the flask with casting, and recover the sand from the pit.

c) Weigh and record the metal poured.

d) Place the recovered sand in its entirety back into the brushed out muller and blend for three (3) minutes. Take three (3) samples from the re-blended shakeout sand. The three (3) "SHAKEOUT" samples shall be taken from within the muller at three locations 120 degrees apart. The sand will be tested for MB clay, compactability, and moisture content, green compression, 1800°F LOI, and 900°F volatile. Each volatile and LOI test requires a separate 50-gram sample from the collected sand. Report results associated with the mold (test number, DA0xx) from which it was taken.

F. Melting:

1. Initial charge:

a) Charge the furnace according to the heat recipe.

b) Place part of the steel scrap on the bottom, followed by carbon alloys, and the balance of the steel.

c) Place a pig on top on top.

d) Bring the furnace contents to the point of beginning to melt over a period of 1 hour at reduced power.
e) Add the balance of the metallic under full power until all is melted and the temperature has reached 2600 to 2700°F.
f) Slag the furnace and add the balance of the alloys.
g) Raise the temperature of the melt to 2700°F and take a DataCast 2000 sample. The temperature of the primary liquidus (TPL) must be in the range of 2200-2350°F.
h) Hold the furnace at 2500-2550°F until near ready to tap.
i) When ready to tap raise the temperature to 2700°F and slag the furnace.
j) Record all metallic and alloy additions to the furnace, tap temperature, and pour temperature. Record all furnace activities with an associated time.

2. Back charging.
a) Back charge the furnace according to the heat recipe,
b) Charge a few pieces of steel first to make a splash barrier, followed by the carbon alloys.
c) Follow the above steps beginning with F.1.e.

3. Emptying the furnace.
a) Pig the extra metal only after the last emission measurement is complete to avoid contaminating the air sample.
b) Cover the empty furnace with ceramic blanket to cool.

G. Pouring:

1. Preheat the ladle.
a) Tap 400 pounds more or less of 2700°F metal into the cold ladle.
b) Casually pour the metal back to the furnace.
c) Cover the ladle.
d) Reheat the metal to 2780 +/- 20°F.
e) Tap 450 pounds of iron into the ladle while pouring inoculating alloys onto the metal stream near its base.
f) Cover the ladle to conserve heat.
g) Move the ladle to the pour position, open the emission hood pour door and wait until the metal temperature reaches 2630 +/- 10°F.
h) Commence pouring keeping the sprue full.
i) Upon completion close the hood door, return the extra metal to the furnace, and cover the ladle.

Test Series DQ – Detailed Process and Source Data

Description	DQ001	DQ002	DQ003	DQ004	DQ005	DQ006	DQ007	DQ008	DQ009	Averages
	12/13/00	12/13/00	12/13/00	12/14/00	12/14/00	12/14/00	12/18/00	12/18/00	12/18/00	
Average Stack Velocity, ft./sec.	15.9	15.9	16.0	15.8	15.9	16.0	15.8	15.8	15.9	15.89
Avg. Stack Pressure, in. Hg	30.09	30.03	30.03	30.18	30.24	30.24	30.40	30.38	30.34	30.21
Stack Flow Rate, scfm	694	693	688	694	691	684	699	695	691	692

Binder fraction = (binder (lbs)/(sand + binder (lbs)) Binder fraction x core weight used in mold = Total Binder Weight Example: (5.0 /(100 + 5.0)) = 0.0476 x 59.60 = 2.894 (lbs binder per mold).

NOTE:1 DQ006 has a high casting metal weight because of a larger than normal pour basin. Retain this test. THC data indicates the impact is less than 5% on the results and statistically, the confidence level in the conclusion is less without this test than with it.

APPENDIX E LISTING OF SUPPORT DOCUMENTS

THIS PAGE INTENTIONALLY BLANK

The following documents contain specific test results, procedures, and documentation used in support of this Test Plan

1. Casting Emission Reduction Program – Foundry Product Testing Guide: Reducing Emissions by Comparative Testing, May 4, 1998.

2. Emissions Testing and Analytical Testing Standard Operating Procedures.

3. Emission Baseline Test Results for the CERP Pre-production Foundry Processes.

4. Evaluation of the Required Number of Replicate Tests to Provide Statistically Significant Air Emission Reduction Comparisons for the CERP Pre-production Foundry Test Program.

THIS PAGE INTENTIONALLY BLANK

APPENDIX F GLOSSARY

THIS PAGE INTENTIONALLY BLANK

t-Test	The calculated T statistic, Ts, is compared against a table value. The table value is a function of the sample size and on the level of confidence desired. For tests with nine sample values each, the T value associated with a confidence level of 95% is 2.12. Calculated values of Ts greater than or equal to this value would indicate that there is 95% or better probability that the differences between the two test series were not the result of test variability.
LOI	Loss On Ignition - the total weight change resulting from combustion in air at 1400^{o}F or 1800^{o}F.
ND	Non Detect, No Data
No Test	Lab testing was not done on this analyte.
HC as Undecane	Calculated by the summation of all area before elution of Hexane to after the elution of Anthracene. The quantity of THC is performed against a five-point calibration curve of Undecane by dividing the total area count from C6 to C14 to the area of Undecane curve from the initial calibration curve.

I have a little bit more info on a different product but similar. Do you have any CERP reports to compare. I only have one that just lists results by a single product in different technologies as opposed to several options per technology.

Compound of Interest	Pouring and Cooling (mg/g of binder)	Shakeout (mg/g of binder)	Total (mg/g of binder)
Total VOC	84.8	20.5	105.3
Carbon Monoxide (CO)	40.0	10.3	50.3
Benzene	4.14	0.08	4.22
Toluene	0.59	not detected	0.59
Ethyl Benzene	0.03	not detected	0.03
Xylenes	0.17	not detected	0.17
Naphthalene	0.89	0.23	1.12
Phenol	6.47	2.97	9.44
Propylene Carbonate	not detected	not detected	not detected
Dimethyl Succinate	5.23	1.12	6.35
Dimethyl Glutarate	12.71	3.00	15.71
Dimethyl Adipate	2.46	0.48	2.94
2-Methyl Naphthalene	not detected	not detected	not detected
1-Methyl Naphthalene	not detected	not detected	not detected
Rapeseed Methyl Ester	0.29	not detected	0.29

Table 2: Hoodstack emissions data for pouring, cooling, and shakeout for ISOCURE 106/206

Subject: RE: PCS Emissions from FWNA Initial Installation

Hi Matthew,
Thanks for the VOC and CO information. In addition to VOC/CO (and other criteria pollutants), we need to estimate the emissions of hazardous air pollutants (HAPs) and Ky regulates other toxic air contaminants (TACs) via an obscure rule. Do you have any organic HAP information? If not, any idea which CERP report may more closely align with the emissions from 109/209? Regards.

For Isocure Focus 109/209 that is used at Fritz Winter we have VOC (mg/g binder) and CO (mg/g binder) for pour and shakeout. OCMA VOC data is below also for them. Sand and resin are from their process.

Isocure Focus 109/209

	Total Voc	CO
Pouring	9.9	8.5
Shakeout	1.9	2.1
Total	11.8	10.6

	Mix 1
Sand	Fritz Winter Gelsar 50
Sand Additive %	-
Sand Additive	-
Lot #	-
Resin % & Ratio	109/209 @ 1.2% & 50/50
Resin Part 1	Isocure 109
Lot #	Lab Made
Resin Part 2	Isocure 209
Lot #	Lab Made
Total Resin	36

109/209	
24 HR Wt. Loss (g.) due to Volatiles	1.01
24 HR Pound Volatile loss/Ton Sand	0.67
24 HR Pound Volatile loss/Pound Binder	0.0281

Subject: PCS Emissions from FWNA Initial Installation

Good morning Matthew,
See page 19, Runs 020-022 of the Rheotec XL+ binder system was used to determine the emission rates from PCS (green sand mold, PUCB core). I've never heard of the product and I don't know why it was selected.

I'll find the core making emission information and send over to you within the hour.

CASE NARRATIVE

All sample aliquots were received at the correct temperature, in the proper containers, with the appropriate preservatives, and within method specified holding times, unless qualified or notated within the report. Where applicable, all MDL (LOD) and RDL (LOQ) values reported for environmental samples have been corrected for the dilution factor used in the analysis. All Method and Batch Quality Control are within established criteria except where addressed in this case narrative, a non-conformance form or properly qualified within the sample results. By my digital signature below, I affirm to the best of my knowledge, all problems/anomalies observed by the laboratory as having the potential to affect the quality of the data have been identified by the laboratory, and no information or data have been knowingly withheld that would affect the quality of the data.

GLOSSARY OF TERMS

Guide to Reading and Understanding Your Laboratory Report

The information below is designed to better explain the various terms used in your report of analytical results from the Laboratory. This is not intended as a comprehensive explanation, and if you have additional questions please contact your project representative.

Results Disclaimer - Information that may be provided by the customer, and contained within this report, include Permit Limits, Project Name, Sample ID, Sample Matrix, Sample Preservation, Field Blanks, Field Spikes, Field Duplicates, On-Site Data, Sampling Collection Dates/Times, and Sampling Location. Results relate to the accuracy of this information provided, and as the samples are received.

Abbreviations and Definitions

MDL	Method Detection Limit.
RDL	Reported Detection Limit.
Rec.	Recovery.
RPD	Relative Percent Difference.
SDG	Sample Delivery Group.
U	Not detected at the Reporting Limit (or MDL where applicable).
Analyte	The name of the particular compound or analysis performed. Some Analyses and Methods will have multiple analytes reported.
Dilution	If the sample matrix contains an interfering material, the sample preparation volume or weight values differ from the standard, or if concentrations of analytes in the sample are higher than the highest limit of concentration that the laboratory can accurately report, the sample may be diluted for analysis. If a value different than 1 is used in this field, the result reported has already been corrected for this factor.
Limits	These are the target % recovery ranges or % difference value that the laboratory has historically determined as normal for the method and analyte being reported. Successful QC Sample analysis will target all analytes recovered or duplicated within these ranges.
Original Sample	The non-spiked sample in the prep batch used to determine the Relative Percent Difference (RPD) from a quality control sample. The Original Sample may not be included within the reported SDG.
Qualifier	This column provides a letter and/or number designation that corresponds to additional information concerning the result reported. If a Qualifier is present, a definition per Qualifier is provided within the Glossary and Definitions page and potentially a discussion of possible implications of the Qualifier in the Case Narrative if applicable.
Result	The actual analytical final result (corrected for any sample specific characteristics) reported for your sample. If there was no measurable result returned for a specific analyte, the result in this column may state “ND” (Not Detected) or “BDL” (Below Detectable Levels). The information in the results column should always be accompanied by either an MDL (Method Detection Limit) or RDL (Reporting Detection Limit) that defines the lowest value that the laboratory could detect or report for this analyte.
Uncertainty (Radiochemistry)	Confidence level of 2 sigma.
Case Narrative (Cn)	A brief discussion about the included sample results, including a discussion of any non-conformances to protocol observed either at sample receipt by the laboratory from the field or during the analytical process. If present, there will be a section in the Case Narrative to discuss the meaning of any data qualifiers used in the report.
Quality Control Summary (Qc)	This section of the report includes the results of the laboratory quality control analyses required by procedure or analytical methods to assist in evaluating the validity of the results reported for your samples. These analyses are not being performed on your samples typically, but on laboratory generated material.
Sample Chain of Custody (Sc)	This is the document created in the field when your samples were initially collected. This is used to verify the time and date of collection, the person collecting the samples, and the analyses that the laboratory is requested to perform. This chain of custody also documents all persons (excluding commercial shippers) that have had control or possession of the samples from the time of collection until delivery to the laboratory for analysis.
Sample Results (Sr)	This section of your report will provide the results of all testing performed on your samples. These results are provided by sample ID and are separated by the analyses performed on each sample. The header line of each analysis section for each sample will provide the name and method number for the analysis reported.
Sample Summary (Ss)	This section of the Analytical Report defines the specific analyses performed for each sample ID, including the dates and times of preparation and/or analysis.

Qualifier	Description
J	The identification of the analyte is acceptable; the reported value is an estimate.
J3	The associated batch QC was outside the established quality control range for precision.
J6	The sample matrix interfered with the ability to make any accurate determination; spike value is low.
V	The sample concentration is too high to evaluate accurate spike recoveries.

Activity:	APE20220003
Permit:	V-16-022-R1

Dear Michelle McCloskey:
Please find the following response to the Division for Air Quality (DAQ) information request dated August 31, 2022.

Emission Calculations

1. Form DEP7007N states that the emission calculations are provided in the emission calculations portion of the permit application. The following information in Appendix C of the submitted permit application must be submitted for form DEP7007N to be deemed complete:

    a. For pages *174, 180, 182, 184, 186, 190, 193, 195, 197, 199, 201, 203, 205, 207, 209, 211,213, 215, 217, 219, 221, 223, 225, 233, 235, 237, 239, 245, 247, 249, 251, 253, 255, 259,261, 263, 284, & 286* of the submitted permit application:

        i. Control efficiencies for each controlled pollutant.

Response:

As explained below, control efficiencies are not used to calculate stack emissions of any pollutant [in this air permit application or in prior air permit applications], excluding the control of amine catalyst used at the PUCB Core Machines #1-#4 (EU39-EU42).

Filterable particulate matter (including PM_{10} and $PM_{2.5}$) air pollution control devices (APCDs) identified in the application include bin vent fabric filters (for silos), booth filters (for the paint lines), cartridge collectors (for Machining and Perforation Lines), other fabric filters (for the two snag grinders) and baghouses. See Attachment #1 that includes revised Tables 2-2 and 2-3 [Perforation Line #1 (EU84) has been added] that are provided on page 92 and 93,

respectively of the air permit application for emission unit air pollution control device assignments.

The other APCD type identified in the application is an Acid Scrubber (CU07) for the control of the amine catalyst used in the phenolic urethane cold box (PUCB) core making process (PUCB Core Machine #1-#4, EU39-EU42). For the Acid Scrubber (CU07), a 98% control efficiency for the amine catalyst is included in the emission factor used to quantify VOC emissions. [See response to comment 8 below]

To calculate controlled PM, PM_{10} and $PM_{2.5}$ emissions (i.e., stack emissions), the application uses the same methodology as the original application. The APCD air volume (in acfm) and BACT-established outlet grain loadings (in gr/dscf) along with the stack temperature are used to determine hourly [Eq. 1] and annual [Eq. 2] stack emission rates from each control device. [differences in standard to actual barometric pressure and moisture content are negligible and therefore ignored]. Again Tables 2-2 and 2-3 identify the emission unit air pollution control assignments.

$$\boldsymbol{PM}\left(\frac{\boldsymbol{lb}}{\boldsymbol{hr}}\right) = \frac{\boldsymbol{gr}}{\boldsymbol{dscf}} \times \boldsymbol{acfm} \times (\mathbf{460}^{\circ}\mathrm{F} + \mathbf{70}^{\circ}\mathrm{F})/(\mathbf{460}^{\circ}\mathrm{F} + \boldsymbol{stack\ temp}^{\circ}\mathrm{F}) \quad \textbf{[Eq. 1]}$$

$$\boldsymbol{PM}\,(\boldsymbol{tpy}) = \boldsymbol{PM}\left(\frac{\boldsymbol{lb}}{\boldsymbol{hr}}\right) \times \frac{\boldsymbol{hours}}{\boldsymbol{year}} \quad \textbf{[Eq. 2]}$$

Using an emission factor and an APCD control efficiency to quantify stack particulate emissions would not be appropriate as inlet conditions (inlet mass emissions, moisture content, particle size, etc.) are unknown. To answer the question, provided the "BACT identified" outlet grain loading for each PM air pollution control device, one would expect PM control efficiencies in the area of 99.5%.

ii. Total emission rates for all emitted pollutants in lb/hr, and tons per year;

Response:

As provided in the original and initial air permit application revision, Attachment #2 provides lb/hr and tons per year emission rates using Eq. 1 and Eq. 2, the estimated air volume from each emissions unit and the BACT identified outlet grain loading.

The total lb/hr and tons/yr differ somewhat from the original application because the secondary capture and control of combustion emission sources are not considered [due to lack of design air volumes].

iii. Method of emission factor calculations.

Response:

Please see Eq. 1 and Eq. 2 as well as the notes at the bottom of each worksheet. See Attachment #2.

b. Some of the current emission units have been updated to include additional pollutants, or updated emission factors. Please provide the basis for new emission factors for each applicable pollutant emitted from the following emission units located in Appendix C:
   i. EUs 07, 08, 09, 10, 13, 17, 19, 20, 21, 33, 39, 40, 41, 42, 45, 35A, 35B, 36 50, 51, 52,53, 57, 59, 60, 61, 62, 63, 64, 65, 66, & 84.

Response:

Overall – As PM, PM_{10} and $PM_{2.5}$ BACT are established for each APCD, it is beneficial to review the total emission rates at the control device level, therefore please see the emission rates for each control device as provided in the air permit application. Emission unit specific PM emission rates in Attachment #2 are provided only to illustrate compliance with 401 KAR 59:010, Section 3(2).

In addition to the above, this response assumes EU67 (Perforation Line #2) in lieu of the above comment-identified EU84 (Perforation Line #1) [which is addressed in a subsequent application].

Induction Furnace #1 (EU07) – See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and baghouse air volume are used to determine the collective emission rates for all emission units exhausted to the particular air pollution control device. The baghouse air volume is then distributed to each emission unit to determine individual unit PM, PM_{10} and $PM_{2.5}$ emission rates). See the notes on page 178 of the permit application for the emission factor basis for the other pollutants of concern. [Note: Provided PM, PM_{10} and $PM_{2.5}$ emission factors are not used as fugitive emissions are not quantified given the buildings are under negative pressure.]

Induction Furnace #2 (EU08) – See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and baghouse air volume are used to determine the collective emission rates for all emission units exhausted to the particular air pollution control device. The baghouse air volume is then distributed to each emission unit to determine individual unit PM, PM_{10} and $PM_{2.5}$ emission rates). See the notes on page 180 of the permit application for the emission factor basis for the other pollutants of concern. [Note: Provided PM, PM_{10} and $PM_{2.5}$ emission factors are not used as fugitive emissions are not quantified given the buildings are under negative pressure.]

Induction Furnace #3 (EU09) – See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and baghouse air volume are used to determine the collective emission rates for all emission units exhausted to the particular air pollution control device. The baghouse air volume is then distributed to each emission unit to determine individual unit PM, PM_{10} and $PM_{2.5}$ emission rates). See the notes on page 182 of the permit application for the emission factor basis for the other pollutants of concern. [Note: Provided PM, PM_{10} and $PM_{2.5}$ emission factors are not used as fugitive emissions are not quantified given the buildings are under negative pressure.]

Induction Furnace #4 (EU10) – See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and baghouse air volume are used to determine the collective emission rates for all emission units exhausted to the particular air pollution control device. The baghouse air volume is then distributed to each emission unit to determine individual unit PM, PM_{10} and $PM_{2.5}$ emission rates). See the notes on page 184 of the permit application for the emission factor basis for the other pollutants of concern. [Note: Provided PM, PM_{10} and $PM_{2.5}$ emission factors are not used as fugitive emissions are not quantified given the buildings are under negative pressure.]

Hot Metal Transfer (EU13) – See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and baghouse air volume are used to determine the collective emission rates for all emission units exhausted to the particular air pollution control device. The baghouse air volume is then distributed to each emission unit to determine individual unit PM, PM_{10} and $PM_{2.5}$ emission rates). [Note: Provided PM, PM_{10} and $PM_{2.5}$ emission factors are not used as fugitive emissions are not quantified given the buildings are under negative pressure.]

Melt and Core/Mold Baghouse Waste Dust Silo (EU17) – See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and bin vent fabric filter air volume are used to determine emission rates). See Tables 2-2 and 2-3 provided in the air permit application for emission unit air pollution control device assignments and the individual fabric filter bin vent worksheet for emission rate calculations.

Mold Silica Sand Silo (EU19) – See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and bin vent fabric filter air volume are used to determine emission rates). See Tables 2-2 and 2-3 provided in the air permit application for emission unit air pollution control device assignments and the individual fabric filter bin vent worksheet for emission rate calculations.

Blend Silo (EU20) – See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and bin vent fabric filter air volume are used to determine emission rates). See Tables 2-2 and 2-3 provided in the air permit application for emission unit air pollution control device assignments and the individual fabric filter bin vent worksheet for emission rate calculations.

Bentonite Silo (EU21) – See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and bin vent fabric filter air volume are used to determine emission rates). See Tables 2-2 and 2-3 provided in the air permit

application for emission unit air pollution control device assignments and the individual fabric filter bin vent worksheet for emission rate calculations.

Mold Making #1 (EU33) – See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and baghouse air volume are used to determine the collective emission rates for all emission units exhausted to the particular air pollution control device. The baghouse air volume is then distributed to each emission unit to determine individual unit PM, PM_{10} and $PM_{2.5}$ emission rates). [Note: Provided PM, PM_{10} and $PM_{2.5}$ emission factors are not used as fugitive emissions are not quantified given the buildings are under negative pressure.]

PUCB Core Machine #1 (EU39) - See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and acid scrubber air volume are used to determine the collective emission rates for all emission units exhausted to the particular air pollution control device. The acid scrubber air volume is then distributed to each emission unit to determine individual unit PM, PM_{10} and $PM_{2.5}$ emission rates). [Note: Provided PM, PM_{10} and $PM_{2.5}$ emission factors are not used as fugitive emissions are not quantified given the buildings are under negative pressure.]

VOC emission rates for each PUCB Core Machine is determined based on the use of resin and catalyst; and then VOC emissions related to the use of core release. See the response to 8. for detail regarding the emission factors used.

PUCB Core Machine #2 (EU40) - See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and acid scrubber air volume are used to determine the collective emission rates for all emission units exhausted to the particular air pollution control device. The acid scrubber air volume is then distributed to each emission unit to determine individual unit PM, PM_{10} and $PM_{2.5}$ emission rates). [Note: Provided PM, PM_{10} and $PM_{2.5}$ emission factors are not used as fugitive emissions are not quantified given the buildings are under negative pressure.]

VOC emission rates for each PUCB Core Machine is determined based on the use of resin and catalyst; and then VOC emissions related to the use of core release. See the response to 8. for detail regarding the emission factors used.

PUCB Core Machine #3 (EU41) - See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and acid scrubber air volume are used to determine the collective emission rates for all emission units exhausted to the particular air pollution control device. The acid scrubber air volume is then distributed to each emission unit to determine individual unit PM, PM_{10} and $PM_{2.5}$ emission rates). [Note:

Provided PM, PM_{10} and $PM_{2.5}$ emission factors are not used as fugitive emissions are not quantified given the buildings are under negative pressure.]

VOC emission rates for each PUCB Core Machine is determined based on the use of resin and catalyst; and then VOC emissions related to the use of core release. See the response to 8. for detail regarding the emission factors used.

<u>PUCB Core Machine #4 (EU42) -</u> See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and acid scrubber air volume are used to determine the collective emission rates for all emission units exhausted to the particular air pollution control device. The acid scrubber air volume is then distributed to each emission unit to determine individual unit PM, PM_{10} and $PM_{2.5}$ emission rates). [Note: Provided PM, PM_{10} and $PM_{2.5}$ emission factors are not used as fugitive emissions are not quantified given the buildings are under negative pressure.]

VOC emission rates for each PUCB Core Machine is determined based on the use of resin and catalyst; and then VOC emissions related to the use of core release. See the response to 8. for detail regarding the emission factors used.

<u>Core Dryer #2 (EU45)</u> – Provided the buildings are under negative pressure, it is assumed any combustion related PM, PM_{10} and $PM_{2.5}$ emissions are secondarily captured by an exhaust point subsequently routed to a baghouse. See Tables 2-2 and 2-3 provided in the air permit application for emission unit air pollution control device assignments.

See the notes at the bottom of the worksheet on page 229 of the application for the basis of non-PM emission rates.

<u>Core Silica Sand Silo A (EU35A)</u> – See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and bin vent fabric filter air volume are used to determine emission rates). See Tables 2-2 and 2-3 provided in the air permit application for emission unit air pollution control device assignments and the individual fabric filter bin vent worksheet for emission rate calculations.

<u>Core Silica Sand Silo B (EU35B)</u> – See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and bin vent fabric filter air volume are used to determine emission rates). See Tables 2-2 and 2-3 provided in the air permit application for emission unit air pollution control device assignments and the individual fabric filter bin vent worksheet for emission rate calculations.

<u>Core Sand Handling and Preparation (EU36)</u> – See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and baghouse air

volume are used to determine the collective emission rates for all emission units exhausted to the particular air pollution control device. The baghouse air volume is then distributed to each emission unit to determine individual unit PM, PM_{10} and $PM_{2.5}$ emission rates). [Note: Provided PM, PM_{10} and $PM_{2.5}$ emission factors are not used as fugitive emissions are not quantified given the buildings are under negative pressure.]

<u>Pouring #1 (EU50)</u> – See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and baghouse air volume are used to determine the collective emission rates for all emission units exhausted to the particular air pollution control device. The baghouse air volume is then distributed to each emission unit to determine individual unit PM, PM_{10} and $PM_{2.5}$ emission rates). See the notes on page 233 of the permit application for the emission factor basis for the other pollutants of concern. [Note: Provided PM, PM_{10} and $PM_{2.5}$ emission factors are not used as fugitive emissions are not quantified given the buildings are under negative pressure.]

<u>Pouring #2 (EU51)</u> – See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and baghouse air volume are used to determine the collective emission rates for all emission units exhausted to the particular air pollution control device. The baghouse air volume is then distributed to each emission unit to determine individual unit PM, PM_{10} and $PM_{2.5}$ emission rates). See the notes on page 235 of the permit application for the emission factor basis for the other pollutants of concern. [Note: Provided PM, PM_{10} and $PM_{2.5}$ emission factors are not used as fugitive emissions are not quantified given the buildings are under negative pressure.]

<u>Mold Cooling (EU52)</u> – See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and baghouse air volume are used to determine the collective emission rates for all emission units exhausted to the particular air pollution control device. The baghouse air volume is then distributed to each emission unit to determine individual unit PM, PM_{10} and $PM_{2.5}$ emission rates). See the notes on page 237 of the permit application for the emission factor basis for the other pollutants of concern. [Note: Provided PM, PM_{10} and $PM_{2.5}$ emission factors are not used as fugitive emissions are not quantified given the buildings are under negative pressure.]

<u>Shakeout Conveyor (EU53)</u> – See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and baghouse air volume are used to determine the collective emission rates for all emission units exhausted to the particular air pollution control device. The baghouse air volume is then distributed to each emission unit to determine individual unit PM, PM_{10} and $PM_{2.5}$ emission rates). See the notes on page 239 of the permit application for the emission factor basis for the other pollutants of concern. [Note: Provided PM, PM_{10} and $PM_{2.5}$ emission factors are not used as fugitive emissions are not quantified given the buildings are under negative pressure.]

Sand Plant Baghouse Waste Dust Silo (EU57) – See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and bin vent fabric filter air volume are used to determine emission rates). See Tables 2-2 and 2-3 provided in the air permit application for emission unit air pollution control device assignments and the individual fabric filter bin vent worksheet for emission rate calculations.

Casting Cooling (EU59) – – See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and baghouse air volume are used to determine the collective emission rates for all emission units exhausted to the particular air pollution control device. The baghouse air volume is then distributed to each emission unit to determine individual unit PM, PM_{10} and $PM_{2.5}$ emission rates). [Note: Provided PM, PM_{10} and $PM_{2.5}$ emission factors are not used as fugitive emissions are not quantified given the buildings are under negative pressure.]

Sorting Conveyor (EU60) – See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and baghouse air volume are used to determine the collective emission rates for all emission units exhausted to the particular air pollution control device. The baghouse air volume is then distributed to each emission unit to determine individual unit PM, PM_{10} and $PM_{2.5}$ emission rates). [Note: Provided PM, PM_{10} and $PM_{2.5}$ emission factors are not used as fugitive emissions are not quantified given the buildings are under negative pressure.]

Steel Shot Blasting #1 (EU61) – See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and baghouse air volume are used to determine the collective emission rates for all emission units exhausted to the particular air pollution control device. The baghouse air volume is then distributed to each emission unit to determine individual unit PM, PM_{10} and $PM_{2.5}$ emission rates). [Note: Provided PM, PM_{10} and $PM_{2.5}$ emission factors are not used as fugitive emissions are not quantified given the buildings are under negative pressure.]

Steel Shot Blasting #2 (EU62) – See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and baghouse air volume are used to determine the collective emission rates for all emission units exhausted to the particular air pollution control device. The baghouse air volume is then distributed to each emission unit to determine individual unit PM, PM_{10} and $PM_{2.5}$ emission rates). [Note: Provided PM, PM_{10} and $PM_{2.5}$ emission factors are not used as fugitive emissions are not quantified given the buildings are under negative pressure.]

<u>Fettling Baghouse Waste Dust Silo (EU63)</u> – See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and bin vent fabric filter air volume are used to determine emission rates). See Tables 2-2 and 2-3 provided in the air permit application for emission unit air pollution control device assignments and the individual fabric filter bin vent worksheet for emission rate calculations.

<u>Auto Grinding #1 (EU64)</u> – See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and baghouse air volume are used to determine the collective emission rates for all emission units exhausted to the particular air pollution control device. The baghouse air volume is then distributed to each emission unit to determine individual unit PM, PM_{10} and $PM_{2.5}$ emission rates). [Note: Provided PM, PM_{10} and $PM_{2.5}$ emission factors are not used as fugitive emissions are not quantified given the buildings are under negative pressure.]

<u>Auto Grinding #2 (EU65)</u> – See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and baghouse air volume are used to determine the collective emission rates for all emission units exhausted to the particular air pollution control device. The baghouse air volume is then distributed to each emission unit to determine individual unit PM, PM_{10} and $PM_{2.5}$ emission rates). [Note: Provided PM, PM_{10} and $PM_{2.5}$ emission factors are not used as fugitive emissions are not quantified given the buildings are under negative pressure.]

<u>Machining Lines (EU66)</u> - See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and cartridge collector air volume are used to determine the emission rate. See Tables 2-2 and 2-3 provided in the air permit application for emission unit air pollution control device assignments. See page 320 of the air permit application for quantification of the emissions.

<u>Perforation Line #2 (EU67)</u> - See Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and cartridge collector air volume are used to determine the emission rate.

This unit was installed following submittal of the air permit application that is the subject of this response. Please see the permit application for the emission calculation methodology.

2. Form DEP7007GG states that the control efficiencies of the control units operate with a control efficiency greater than or equal to 99%. Form DEP7007N states that the estimated control efficiency for each control device is greater than or equal to 99.5%. According to the Kentucky emission inventory system, each control device has a different control efficiency, often less than

99%. In order for forms DEP7007GG to be deemed complete and accurate, all control equipment information should be included in the form DEP7007GG.

a. Please update page 884 of the permit application, the form needs to be completed for all control devices, and all boxes should be completed.

Response:

Attachment #3 includes the updated DEP7007GG that changes the pollutant removal % from 99 to 99.5+ to match Form DEP7007N for the fabric filters.

3. For EUs 19, 20, 21, 35A, 35B, 57, and 63:

a. Please confirm that there is no condensable particulate expected from each emission unit where the application identifies that PM is assumed to be equal to PM2.5 and PM10.

Response:

The Mold Silica Sand Silo (EU19), Blend Silo (EU20), Bentonite Silo (EU21), Core Silica Sand Silo A (EU35A) and Core Silica Sand Silo B (EU35B) receive virgin solid material pneumatically conveyed from trucks. Temperatures are ambient and no condensable particulate matter is expected.

The Sand Plant Baghouse Waste Dust Silo (EU57) and Fettling Baghouse Waste Dust Silo (EU63) are receiving solid material (baghouse dust from CU06 and CU11) at ambient conditions. No condensable particulate matter is expected.

b. Are the provided emission factors from Ohio EPA RACM pre or post-control emission factors? Any additional documentation should be provided.

Response:

See above response to b. regarding the emission calculation methodology for these emission units. In summary, see Eq.1 and 2 for PM, PM_{10} and $PM_{2.5}$ emission calculation methodology (this methodology is identical to that identified in the original and 1st application revision whereby the BACT identified outlet grain loading and bin vent fabric filter air volume are used to determine emission rates). See Tables 2-2 and 2-3 in Attachment #1 for emission unit air pollution control device assignments and the individual fabric filter bin vent worksheet for emission rate calculations. As the processes are enclosed there are no fugitive emissions identified.

The identified emission factors are provided only in the event it is necessary to quantify fugitive emissions.

The emission factors from Ohio EPA RACM are pre-controls. The foundry and cement (silo)-specific sections of Ohio EPA RACM is provided as Attachment #4.

4. For EUs 33, 34, and 43:

a. Why was stack test data emission factors not used for the emission units, rather than the provided emission factors from Ohio RACM, Table 2.7-1.

Response:

Mold Making #1 (EU33) and Mold Making #2 (EU34) have either no or limited amounts of particulate matter. As indicated on the emission calculation sheet, any emissions from these operations would be captured by the Core/Mold Baghouse (CU08). Emission factors are only provided in the event fugitive emissions are to be quantified. Eq. 1 and Eq. 2 are used to determine emission rates in lb/hr and tpy at both the APCD and emission unit level (as provided in Attachment #2).

Core Wash Station #1 (EU43) emissions are associated with the VOC content of the wash. VOC emissions are determined based on a mass balance of the wash VOC content.

b. Please confirm that there is no condensable particulate expected from each emission unit where PM is equal to PM2.5 and PM10.

Response:

For Mold Making #1 (EU33) and Mold Making #2 (EU34), these operations process prepared green sand into molds. The molds are prepared solid material at ambient temperature and are therefore not expected to have condensable particulate matter.

As shown in Table 2-2 and 2-3, emissions are secondarily captured by the identified air pollution control device. Condensable particulate matter are quantified for all operations at the control device stack [where the condensable matter is measured and where compliance with the BACT emission limits are demonstrated].

Core Wash Station #1 (EU43) emissions are only associated with the evaporative VOCs from the wash. No filterable or condensable particulate emissions are expected from the operation.

c. Are the provided emission factors from Ohio EPA RACM pre or post-control emission factors? Again, additional documentation thereof would be useful.

Response:

As discussed above, the convention of the current Air Permit, the emissions from these operations are estimated based on BACT/outlet grain loadings and air volumes [see Eq. 1 and Eq. 2]. The emission factors provided are only provided in the event it is necessary to provide fugitive emission calculations.

The emission factors from Ohio EPA RACM are pre-controls. The foundry- and cement (silo)-specific section of Ohio EPA RACM has been provided as Attachment #4.

5. Please provide emission factors for both breathing and working losses along with the already provided Diesel Storage Tank properties on page 283 of the permit application for EU 75.

Response:

As TANKS emissions Estimation Software is no longer supported by USEPA, as recommended by USEPA, the equations and algorithms specified in AP-42 Chapter 7 is used for estimating VOC emissions from the Diesel Storage Tank (EU75). Breathing losses are estimated at 0.2551 lb VOC/year per 24,000 gallons or 0.011 lb VOC/1,000 gallons. Working losses are determined to be 137.3876 lb VOC/year or 5.724 lb VOC/1,000 gallons.

6. For EUs 79, 80, 81, and 82 VOC emission factors listed in Appendix C, please correct the emission factor to lb/ton.

Response:

[Aside: Likely Core Wash Station #1 (EU43) should be identified in this comment]

VOC emissions from Core Wash Station #1 (EU43), Core Wash Station #2 (EU79), Core Wash Station #3 (EU80), Core Wash Station #4 (EU81) and Rust Prohibitive (EU82) are based on the weight of material used in "tons/hr" (based on hourly usage capacity) and "tons/year" (based on an annual usage limit restriction) and the VOC content of the material. As indicated on the emission calculation worksheets, the emission factor is provided in "% by wt." The hourly and annual VOC emissions are determined by multiplying the usage weight (in tons/hr and tons/year) by the % by weight VOC.

7. For each unit's HAP emission calculation sheet in Appendix C, please include an emission factor for every potential HAP for each corresponding emission unit. If no HAPs are expected, please do not include a HAP emission calculation sheet, instead, provide information regarding the reason HAPs are not expected.

Response:

To determine the emissions of inorganic HAP/TAC emissions, baghouse dust analysis is to quantify the emissions of HAPs/TACs from all types of fabric filters (i.e., baghouses, cartridge collectors, etc.). Please reference Table 2-2 and 2-3 for the particular particulate matter control device and associated inorganic HAP emissions.

Other HAP emissions are either grouped (e.g., pouring, cooling and shakeout) to improve accuracy or provided at the emission unit level.

Rather than address workbook formatting issues, Attachment #5 provides a basis for the identification of HAPs from a specific operation.

8. The Division's current emissions inventory lists three process IDs for each of EUs 39, 40, 41, and 42: 1000 ft3 catalyst processed, Pounds Release Processed, and Pounds Binder Processed. However, the submitted application does not include the VOCs from the binder processed. Please clarify the absence of the VOC from the binder processing in the application. With your response, please provide detailed calculations for the new VOC emission factor listed on pages 213, 217, 221 and 225 of the submitted permit application.

Response:

To quantify the VOC emissions from the PUCB Core Machines [PUCB Core Machine #1 (EU39), PUCB Core Machine #2 (EU40), PUCB Core Machine #3 (EU41) and PUCB Core Machine #4 (EU41)], the emissions from the binder system (resin and catalyst) and the emissions from the core release are quantified on separate worksheets [i.e., there are two worksheets per core machine). The emissions from the core release are determine using the maximum hourly and annual core release and the maximum VOC content (as identified by vendor provided information). This is documented on the core release worksheet.

Regarding the resin and catalyst VOC emission factor, the factor is the additive sum of the VOC emission rate for the resin plus the VOC emission rate for the catalyst.

The VOC emission factor for the resin is determined by the following:

0.65 lb/ton of sand (per VOC OCMA weight loss test)
125% (emission factor adjustment based on stack test results)
1.25/1 (adjustment to OCMA weight loss test to reflect the FW maximum resin usage of 1.25% divided by the resin usage during the OCMA weight loss test.
= 1.016 lb/ton of sand

The VOC emission factor for the catalyst is determined by the following:

2000 (lb/ton)
1.25% (resin% usage based on sand)
10% (catalyst % based on resin)
=2.5 lb catalyst per ton of sand
1-98% (acid scrubber 98% control efficiency of amine catalyst)
=0.05 lb/ton of sand

Total VOC emission factor for resin and catalyst is 1.016 + 0.05 = 1.066 lb/ton of sand

Permit Modifications

1. The Division may consider grouping emission units if the processes operate in sequence in a continuous manner. Otherwise, individual processes need to be in the permit application and identified separately, if there are requested changes or to update information. Please provide additional information to support combining emission units into the requested groups. According to the permit application the requested emission unit groups are as follows:

    a. On page 915 of the permit application, EU 01 will include EU 02;

Response:

Scrap Steel Storage (EU01) and Alloy Storage (EU02) are co-located under roof on the Northeast side of the plant. The request is that both EU01 and EU02 be combined into the Charge Handling emission unit EU01. The request to combine these emission units is being made due to an error in the original air permit application submitted to DAQ.

The "charge materials" include scrap, fluxes and alloys some of which are received in bulk containers. . The "charge material" are deposited (i.e., handled) into one of four charge hoppers which carry the "charge" through roll-up doors to one of the four furnaces. The receiving and storage of all "charge materials" are addressed under the same SCC (30400315) for "charge handling." Should it be necessary to quantify the uncontrolled emissions for "charge handling", the emissions are determined based on the "tons metal charged" and not the scrap, flux or alloys received. The identification of the "Charge Handling" emission unit that includes the receipt and storage of scrap, flux and alloys is industry practice.

b. On page 916 of the permit application, EU 13 will include EU 14;

Response:

It is requested that Transport Ladle #1 (EU13) and Transport Ladle #2 (EU14) be combined into a single operation identified as Hot Metal Transfer (EU13) due to an error in the initial air permit application submitted to DAQ.

Emissions result from the transfer of molten metal from the induction furnaces to the pouring furnace. Due to abrasion and thermal degradation, the ladle refractory must be repaired. When a ladle is taken out of service due to degradation, a repaired ladle takes its place. Whether there is one, two or even three ladles, the uncontrolled emissions from Hot Metal Transfer would be calculated based on the molten metal transferred and not be whether the metal is transported by any particular ladle. The identification of the emission unit Hot Metal Transfer is industry practice.

c. On pages 917, 918 and 919 of the permit application, EU 22 will include EUs 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 48 and 49;

Response:

Please note there is no EU25 in the current air permit or in the most recent application. In addition to the above identified emission units, the current air permit application has requested the Sand Cooler (EU54), Used Mold and Core Sand Storage (EU55) and Sand Screening (EU56) be combined into a single emissions unit Mold Sand Handling and Preparation (EU22). This request is being made to correct the initial air permit application submitted to DAQ.

The Mold Silica Sand Bin (EU22), Blend Bin (EU23), Bentonite Bin (EU24), Mold Silica Sand Weigh Hopper (EU26), Blend Weigh Hopper (EU27), Bentonite Weigh Hopper (EU28), Dust Weigh Hopper (EU29), Green Sand Mixer #1 (EU30), Green Sand Mixer #2 (EU31), Green Sand Mixer #3 (EU32), Mold Assembly #1 (EU48), Mold Assembly #2 (EU49), have been requested to be combined into Sand Cooler (EU54), Used Mold and Core Sand Storage (EU55) and Sand Screening (EU56) be combined into a single emissions unit Mold Sand Handling and Preparation (EU22) and designated as EU22.

Mold Sand Handling and Preparation is a continuous operation, where sand is returned for preparation and then reuse by Mold Making #1 (EU33) or Mold Making #2 (EU34). Sand is

transported between equipment via conveyors, elevators and gravity. The emission unit includes sand storage (in bins and hoppers), sand processing (through Screens, Coolers and Mixers) and subsequently reused as molding sand. The return sand is supplemented with new additions of silica sand, bentonite and a blend of generally carbonaceous materials to form new molds as Mold Making #1 (EU33) and Mold Making #2 (EU34). Uncontrolled emissions for the equipment at large is identified under SCC 30400350, "Sand Grinding/Handling."

d. On page 18 of the permit application, EU 36 will include EUs 37 and 38; and

Response:

These 3 units, Sand Classifier (EU36), Silica Sand Bin (UE37) and Weigh Hopper (EU38) are combined into a single unit identified as Core Sand Handling and Preparation.

The units are a continuous operation. When sand is needed for core making, sand is automatically and pneumatically conveyed from Core Silica Sand Silo A (EU35A) or Core Silica Sand Silo B (EU35b) to the Sand Classifier for sizing. Once sized, the sand is gravity fed to the Sand Bin and then gravity fed to the Weigh Hopper prior to being discharged to a mixer where the weighed sand is mixed with resin.

The above identified units are stacked on top of each other above the core machine and are not necessarily identifiable from one another. The Weigh Hopper receives sand directly from the Sand Bin. Binder is added and mixed to be delivered to the Core Machine calling for sand (either Core Machine #1 or Core Machine #2).

e. On page 921 of the permit application, EU 66 will include EU 67.

Response:

While other portions of the air permit application is correct, Page 921 of the permit application should not have identified combining existing Machining Lines (EU66) and Perforation Line (EU67) into a single emission unit.

[Please note subsequent to submittal of this air permit application, a permit was received for Perforation Line #1 (EU84). FWNA would like to identify EU67 as Perforation Line #2.

2. Due to the volume of changes requested, to help with timely processing of the permitting action, the Division requests that a red-line mark-up copy of the permit be submitted with your reply.

Response:

See Attachment #6

3. Does the facility still require the alternate operating scenarios included in Section H of the permit, or can they be removed because the construction phases have been completed?

Response:

No, the alternative operating scenarios included in Section H of the permit can be removed. The existing air permit identified emission unit, Paint Booth #3 (EU70), is not included in this permit application. Please incorporate Alternate Scenario #1 into the main permit for Emission Units Paint Line #1 (EU71), Paint Line #2 (EU69) and Paint Line #3 (EU68).

Additional Information

1. On page 263 of the permit application and elsewhere, Perforation Line 1 is designated as EU67. However, in a recent minor revision dated February 21, 2022, EU 84 – Perforation Line #1 was added into the Division's inventory. Please clarify if the facility only wants to change the description of an existing designation for EU 67 – Drilling and Milling - would the process of EU 67 be different or the same as the recently applied for EU 84?

Response:

The installation of Performance Line #1 (EU84) was not known prior to the submittal of the air permit application that is the subject of this response. During preparation of the air permit application for EU84 it was determined that the line would be identified as Perforation Line #1 and that the appropriate name for EU67 was Perforation Line #2.

The current description of 8 turning lathe lines (EU66) and 2 milling and drilling lines (EU67) is confusing as both car lines (7) and truck lines (2) all perform lathing, milling and drilling operations with some parts going the additional step at Perforation line 2 (a drilling operation).

2. Are building vents 01A, 01B, 02A, and 02B still constructed/installed? If they are, how are emissions prevented from passing through; are the vents are closed, how are they sealed? Are there any other egress points for emissions within the enclosed spaces near the vents?

Response:

Building Vent 01A is installed in the Fettling area. Buidling Vent 01B is installed near the Charge Handling area. Building Vent 02A is installed near the center of the Machining Building. Building Vent 02B is not installed.

Building Vents 01A and 01B are not used and the louvers are closed as negative pressure is maintained in the Foundry Building.

Following the study of the ventilation in Machining Building as it pertains to the quality of our coating operations, a determination was made that Vent 02A would not be used and the louvers would remain closed.

Aside: There are two other vents installed in the Foundry Building. One Building Vent is near Building Vent 01A near the Charge Handling Area and the other is near the location of the Electric Induction Furnaces (EU07 – EU10). Neither are used and louvers are closed. Negative pressure is maintained in the Foundry.

3. Where does the facility store waste dust from the baghouses?

Response:

Both the Melt Baghouse (CU01) and Core/Mold Baghouse (CU08) pneumatically convey baghouse dust to Melt and Core/Mold Baghouse Waste Dust Silo (EU17); The Sand Plant Baghouse (CU06) pneumatically conveys sand to the Sand Plant Waste Sand Silo (EU57) and the Fettling Baghouse (CU11) pneumatically convey sand to Fettling Baghouse Waste Dust Silo (EU63). [Note: As identified above both the Melt Baghouse (CU01) and the Core/Mold Baghouse (CU08) transport to the same waste silo, Melt Waste Dust Silo (EU17)]

Please contact me at eddie.butler@fritzwinter.us or at (270) 813-4000 should you have any questions regarding the attached response.

Respectfully submitted,

Eddie G Butler

Eddie G Butler
EHS Manager

Franklin, Kentucky

Maximum Yearly Capacity
91,586 Tons/Year

Flow Diagram Designation
Charge Handling
EU01

Maximum Hourly Capacity
25.30 Tons/Hour

Process Description:
Fritz Winter North America, LP
Charge Handling
Control Device: Melt Baghouse (CU01) Note 4
SCC Code:
Control Device Outlet: 0.0020 gr/dscf
Airflow: 5,442 acfm
Stack Gas Temperature: °F

Facility Process Name:	**Criteria Pollutants**								
Charge Handling									
Emission Factor Basis:	**PM**	**PM10**	**PM2.5**	**SOx**	**NOx**	**VOC**	**CO**	**Lead**	**CO_2e**
Emission Factors:	0.07	0.07	0.06						
(source)	Note 1	Note 1	Note 2						
Capture Efficiency	100.00	100.00	100.00						
Control Efficiency									
Building Capt. Eff									
Maximum Stack Emission Rate:									
Hourly (lb/hr)	0.107	0.107	0.107						
Annual (TPY)	**0.471**	**0.471**	**0.471**						
Maximum Fugitive Emission Rate:									
Hourly (lb/hr)									
Annual (TPY)									
Total Emission Rate:									
Hourly (lb/hr)	0.107	0.107	0.107						
Annual (TPY)	**0.471**	**0.471**	**0.471**						

PROPOSED OPERATING SCHEDULE
24 HRS/DAY
8,760 HRS/YEAR

Note 1: Gutow Article, Modern Casting; January 1972; PM emissions from Raw material handling (0.04 lbs/ton) and charge makeup (0.03 lbs/ton) released to the atmosphere. All PM emission were conservatively assumed to be PM-10 emissions.
Note 2: Emission factor based on USEPA PM Calculator (March 2012) PM to $PM_{2.5}$ ratio and uncontrolled PM emission factor.
Note 3: The Alloy Storage emission unit (EU02) is included in this emission unit.
Note 4: Secondary capture of fugitive emissions per testing conducted pursuant to permit term EG01,3.I

EXAMPLE CALCULATIONS:
Maximum Emission Rate (lb/hr) {building exhausts} = (Emission Factor lb/ton) x (Maximum Hourly Rate tph) x (% returns/100 for PM10 only) x (1- %fugitive rate/100)
Maximum Emission Rate (lb/hr) {fugitive} = (Emission Factor lb/ton) x (Maximum Hourly Rate tph) x (%returns for PM10 only) x (% fugitive emissions rate/100)
Annual (TPY) Emission Rates = (lb/hr emission rate) x (Maximum Annual Melt Rate) / (Maximum Hourly Melt Rate) / (2000 lbs/ton)

	Annual (TPY)	**2.336**	**2.336**	**2.336**			**1.065**	**5.724**		

PROPOSED OPERATING SCHEDULE
24 HRS/DAY
8,760 HRS/YEAR

Note 1: Emission factor from FIRE 6.25 SCC 3-04-003-03
Note 2: Emission factor based on USEPA PM Calculator (March 2012) PM to PM2.5 ratio and uncontrolled PM emission factor.
Note 3: March 2020 compliance test
Note 4: See below HAPs calculations
Note 5: Secondary capture of fugitive emissions per testing conducted (EG01,3.I)

EXAMPLE CALCULATIONS:
Maximum Stack Emission Rate (lb/hr) {PM & PM-10}=(gr/acfm) x (acfm) x (1 lb / 7000 grains) x (60 min / 1 hr)
Maximum Stack Emission Rate (lb/hr) {Lead}=(gr/acfm) x (acfm) x (1 lb / 7000 grains) x (60 min / 1 hr)*(Lead EF/PM EF)
Maximum Annual (Ton/yr) Stack Emission Rates = (lb/hr emission rate) x (hours of operation per year at max. rate) x (ton/2000 lbs)
Maximum Fugitive Emission Rate (lb/hr) = ((1 - Capture Efficiency/100) x (Emission Factor) x (Melt ton/hr) x (1-(Settling Factor)/100)
Maximum Annual Fugitive Emissions (ton/yr)= (Hourly fugitive emissions (lb/hr)/ hourly Process rate (ton/hr) x (Annual process rate (tons/yr) x (ton/2000 lbs)
Total Emission Rate (lb/hr) = (Maximum Stack Emission Rate lb/hr) + (Maximum Fugitive Emission Rate lb/hr)
Total Emission Rates Annual (TPY)= (annual stack emissions (ton/yr)) + (annual fugitive emissions (ton/yr))

Maximum Yearly Capacity
91,586 Tons/Year

Flow Diagram Designation
Melt and Core/Mold Baghouse Dust Silo
EU17

Maximum Hourly Capacity
25.30 Tons/Hour

Process Description:
Fritz Winter North America, LP
Melt and Core/Mold Baghouse Dust Silo
Control Device: Melt and Core/Mold BHs Dust Silo Bin Vent Filter (CU02)
SCC Code:
Control Device Outlet: 0.0030 gr/dscf
Airflow: 600 acfm
Stack Gas Temperature: 100 °F

Facility Process Name:		**Criteria Pollutants**								
	Melt and Core/Mold Baghouse Dust Silo									
Emission Factor Basis:		**PM**	**PM10**	**PM2.5**	**SOx**	**NOx**	**VOC**	**CO**	**Lead**	**CO_2e**
Emission Factors:	lb/ton	0.24	0.24	0.24						
(source)		Note 1	Note 2	Note 2						
	Capture Efficiency	100.00	100.00	100.00						
	Control Efficiency									
	Building Capt. Eff									
Maximum Stack Emission Rate:										
	Hourly (lb/hr)	0.015	0.015	0.015						
	Annual (TPY)	**0.064**	**0.064**	**0.064**						
Maximum Fugitive Emission Rate:										
	Hourly (lb/hr)									
	Annual (TPY)									
Total Emission Rate:										
	Hourly (lb/hr)	0.015	0.015	0.015						
	Annual (TPY)	**0.064**	**0.064**	**0.064**						

PROPOSED OPERATING SCHEDULE
24 HRS/DAY
8,760 HRS/YEAR

Note 1: Emission factor from Ohio EPA RACM, Table 2.22-1, pg 2-474, Silo Vent
Note 2: Assumes $PM_{2.5}$ and PM_{10} is equal to PM

EXAMPLE CALCULATIONS:
Maximum Stack Emission Rate (lb/hr) {PM,PM-10} =(gr/acfm) x (acfm) x (1 lb / 7000 grains) x (60 min / 1 hr)
Maximum Annual (Ton/yr) stack Emission Rates = (lb/hr emission rate) x (hours of operation per year at max. rate) x (ton/2000 lbs)
Maximum Fugitive Emission Rate (lb/hr) = ((1 - Capture Efficiency/100) x (Emission Factor) x (Melt ton/hr) x (1-(Settling Factor)/100)
Maximum Annual Fugitive Emissions (ton/yr)= (Hourly fugitive emissions (lb/hr)/ hourly Process rate (ton/hr) x (Annual process rate (tons/yr) x (ton/2000 lbs)
Total Emission Rate (lb/hr) = (Maximum Stack Emission Rate lb/hr) + (Maximum Fugitive Emission Rate lb/hr)
Total Emission Rates Annual (TPY)= (annual stack emissions (ton/yr)) + (annual fugitive emissions (ton/yr))

Note 2: WebFIRE (Aug 20, 2021) SCC 30400320
Note 3: Emission factors taken from the document entitled "Foundry Process Emission Factors: Baseline Emissions from Automotive Foundries in Mexico"; (CERP-Mexico); Table 5.12
Note 4: FWNA Original Application/BACT, using Waupaca RBLC entries and air volumes
Note 5: Emission factor based on USEPA PM Calculator (March 2012) PM to PM2.5 ratio and uncontrolled PM emission factor.

EXAMPLE CALCULATIONS:
Maximum Stack Emission Rate (lb/hr) {PM,PM-10} =(gr/acfm) x (acfm) x (1 lb /
Maximum Stack Emission Rate (lb/hr) {Lead} =(gr/acfm) x (acfm) x (1 lb / 7000 grains) x (60 min / 1 hr) x (
Maximum Stack Emissions Rate (lb/hr) {SOx,NOx, VOC, CO} =(Max. Rated Capa
Maximum Annual (Ton/yr) PM, PM10 and lead stack Emission Rates = (lb/hr emission rate) x (hours of op
Maximum Annual (ton/yr) SOx NOx, VOC and CO stack emissions= (Hourly stack emissions (lb/hr)/ hourly Process rate (ton/hr) x (Annual process rate (tons/yr) x (ton/2000 lbs)
Maximum Fugitive Emission Rate (lb/hr) = ((1 - Capture Efficiency/100) x (Emission Factor) x (Melt ton/hr) x (1-(Settling Factor)/100)
Maximum Annual Fugitive Emissions (ton/yr)= (Hourly fugitive emissions (lb/hr)/ hourly Process rate (ton/hr) x (Annual process rate (tons/yr) x (ton/2000 lbs)
Total Emission Rate (lb/hr) = (Maximum Stack Emission Rate lb/hr) + (Maximum Fugitive Emission Rate lb/hr)
Total Emission Rates Annual (TPY)= (annual stack emissions (ton/yr)) + (annual fugitive emissions (ton/yr))

Maximum Yearly Capacity
15.50 Tons/Year

Flow Diagram Designation
Paint Line #1
EU71

Maximum Hourly Capacity
3.54 Lbs/Hour

Process Description:
Fritz Winter North America, LP
Paint Line #1
Control Device: Paint Line #1 Booth Filter (CU17)
SCC Code:
Control Device Outlet: 0.0015 gr/dscf
Airflow: 20,310 acfm
Stack Gas Temperature: °F

Facility Process Name:		**Criteria Pollutants**								
	Paint Line #1									
Emission Factor Basis:		**PM**	**PM10**	**PM2.5**	**SOx**	**NOx**	**VOC**	**CO**	**Lead**	**CO_2e**
Emission Factors:	lb/lb	0.34	0.34	0.34			0.14			
(source)		Note 1	Note 2	Note 2			Note 3			
Capture Efficiency		100.00	100.00	100.00			100.00			
Control Efficiency		99.50	99.50	99.50						
Transfer Efficiency		70.00	70.00	70.00						
Maximum Stack Emission Rate:										
Hourly (lb/hr)		0.301	0.301	0.301			0.513			
Annual (TPY)		**1.318**	**1.318**	**1.318**			**2.244**			
Maximum Fugitive Emission Rate:										
Hourly (lb/hr)										
Annual (TPY)										
Total Emission Rate:										
Hourly (lb/hr)		0.301	0.301	0.301			0.513			
Annual (TPY)		**1.318**	**1.318**	**1.318**			**2.244**			

PROPOSED OPERATING SCHEDULE
24 HRS/DAY
8,760 HRS/YEAR

Note 1: Geomet 360 SDS (midpoint of % solids range)
Note 2: Assumes PM_{10} and $PM_{2.5}$ is equal to PM
Note 3: Geomet 360 Air Quality Data Sheet (1.6 lb/gal VOC at coating density of 11.05 lbs/gal
Note 4: Above quantities and emission factors disregard DI water that is used as a thinner

EXAMPLE CALCULATIONS:
Maximum Stack Emission Rate (lb/hr) {PM,PM-10} =(gr/acfm) x (acfm) x (1 lb / 7000 grains) x (60 min / 1 hr)
Maximum Annual (Ton/yr) stack Emission Rates = (lb/hr emission rate) x (hours of operation per year at max. rate) x (ton/2000 lbs)
Maximum Fugitive Emission Rate (lb/hr) = ((1 - Capture Efficiency/100) x (Emission Factor) x (Melt ton/hr) x (1-(Settling Factor)/100)
Maximum Annual Fugitive Emissions (ton/yr)= (Hourly fugitive emissions (lb/hr)/ hourly Process rate (ton/hr) x (Annual process rate (tons/yr) x (ton/2000 lbs)
Total Emission Rate (lb/hr) = (Maximum Stack Emission Rate lb/hr) + (Maximum Fugitive Emission Rate lb/hr)
Total Emission Rates Annual (TPY)= (annual stack emissions (ton/yr)) + (annual fugitive emissions (ton/yr))

Maximum Yearly Capacity
135.0 Tons/Year Note 1

Flow Diagram Designation
Core Wash Station #3
EU80

Maximum Hourly Capacity
0.338 Tons/Hour Note 1

Process Description:
Fritz Winter North America, LP
Core Wash Station #3
Control Device: Core/Mold Baghouse (CU08)
SCC Code:
Control Device Outlet: 0.0020 gr/dscf
Airflow: 652 acfm
Stack Gas Temperature: °F

Facility Process Name:		**Criteria Pollutants**								
	Core Wash Station #3									
Emission Factor Basis:		**PM**	**PM10**	**PM2.5**	**SOx**	**NOx**	**VOC**	**CO**	**Lead**	**CO_2e**
Emission Factors:	% by wt.						0.76%			
(source)							Note 2			
Capture Efficiency		100.000	100.000	100.000						
Control Efficiency										
Building Capt. Eff										
Maximum Stack Emission Rate:										
Hourly (lb/hr)		0.013	0.013	0.013			5.130			
Annual (TPY)		**0.056**	**0.056**	**0.056**			**1.026**			
Maximum Fugitive Emission Rate:										
Hourly (lb/hr)										
Annual (TPY)										
Total Emission Rate:										
Hourly (lb/hr)		0.013	0.013	0.013			5.130			
Annual (TPY)		**0.056**	**0.056**	**0.056**			**1.026**			

PROPOSED OPERATING SCHEDULE
24 HRS/DAY
8,760 HRS/YEAR

Note 1: Usage from original permit application
Note 2: VOC Content from original permit application; ASK rep indicated less than 0.1% VOC

EXAMPLE CALCULATIONS:
Maximum Fugitive Emission Rate (lb/hr) = (Maximum Hourly Production gal/hr) x (VOC content lb/gal)
Maximum Annual Fugitive Emissions (ton/yr)= (Maximum Annual Production gal/yr) x (VOC content lb/gal) / (2000 lb/ton)

2.22 CONCRETE BATCHING PLANTS

2.22.1 Process Description[1]

There are three general types of concrete batching plants. They are batching (into transit-mix trucks) plants, central-mix plants and dry-batching (into flat-bed trucks) plants.

Concrete batching plants store, convey, measure and blend the components for making concrete. The plants are similar in the method by which the solid raw materials (sand, aggregate and cement) are received, stored, transferred and blended, but differ with respect to where the water is added to the mix.[2]

The raw materials are delivered to the plant by rail or truck. The cement is transferred pneumatically (most commonly) or by bucket elevator to elevated storage silos. The sand and aggregate are generally stored on the ground and transferred to elevated bins via belt conveyor or bucket elevator. From the overhead bins, the materials are dropped into weigh hoppers which weigh out the proper amount of each material.

In batching plants that load transit-mix trucks, the weighed aggregates and cement are dropped into a receiving hopper. The required amount of water is injected into the flowing stream of solids as the mixture of material is emptied from the receiving hopper into the transit-mix truck. The transit-mix trucks mix the batch en route to the site where the concrete is to be poured.

Dry-batch plants mix sand, aggregate and cement and then dump this dry mix into flat-bed trucks. These trucks transport the batch to paving machines at the job site where water is added and mixing takes place.

A central-mix plant uses a centrally located mixer to make wet concrete. The wet concrete is emptied into open-bed trucks and

transported to the job site where the concrete is to be poured.

A process flow diagram for concrete batching is shown in Figure 2.22-1. One of the fugitive emission sources which is common to all concrete batch plants, but not specifically included in this section, is plant roads. Discussion of this fugitive dust source is presented in Section 2.1. Other fugitive emission sources at concrete batching plants include the sand and aggregate storage areas, transferring and conveying operations, cement unloading, cement silo vents, weigh hopper loading, mixer loading (central-mix plants), transit-mix truck loading operations (batching plants) and flat-bed truck loading operations (dry-batching plants).

2.22.2 Fugitive Dust Emission Factors

The potential sources of fugitive dust from concrete batching are shown in Table 2.22-1, along with the corresponding emission factors. All of these factors are based on either engineering judgment or visual observations. No details are available concerning the methodology of development. The reliability of these types of estimates is poor.

The emission factors for plant haul roads are not included in Table 2.22-1. Emission factors for these sources are listed in Section 2.1.

2.23.3 Particle Characterization

Practically all the fugitive dust generated at concrete batching plants is cement dust since most of the sand and aggregate used is damp. Therefore, this section will only concentrate on particle characteristics of cement dust.

The typical oxide composition of cement dust is as follows.[3]

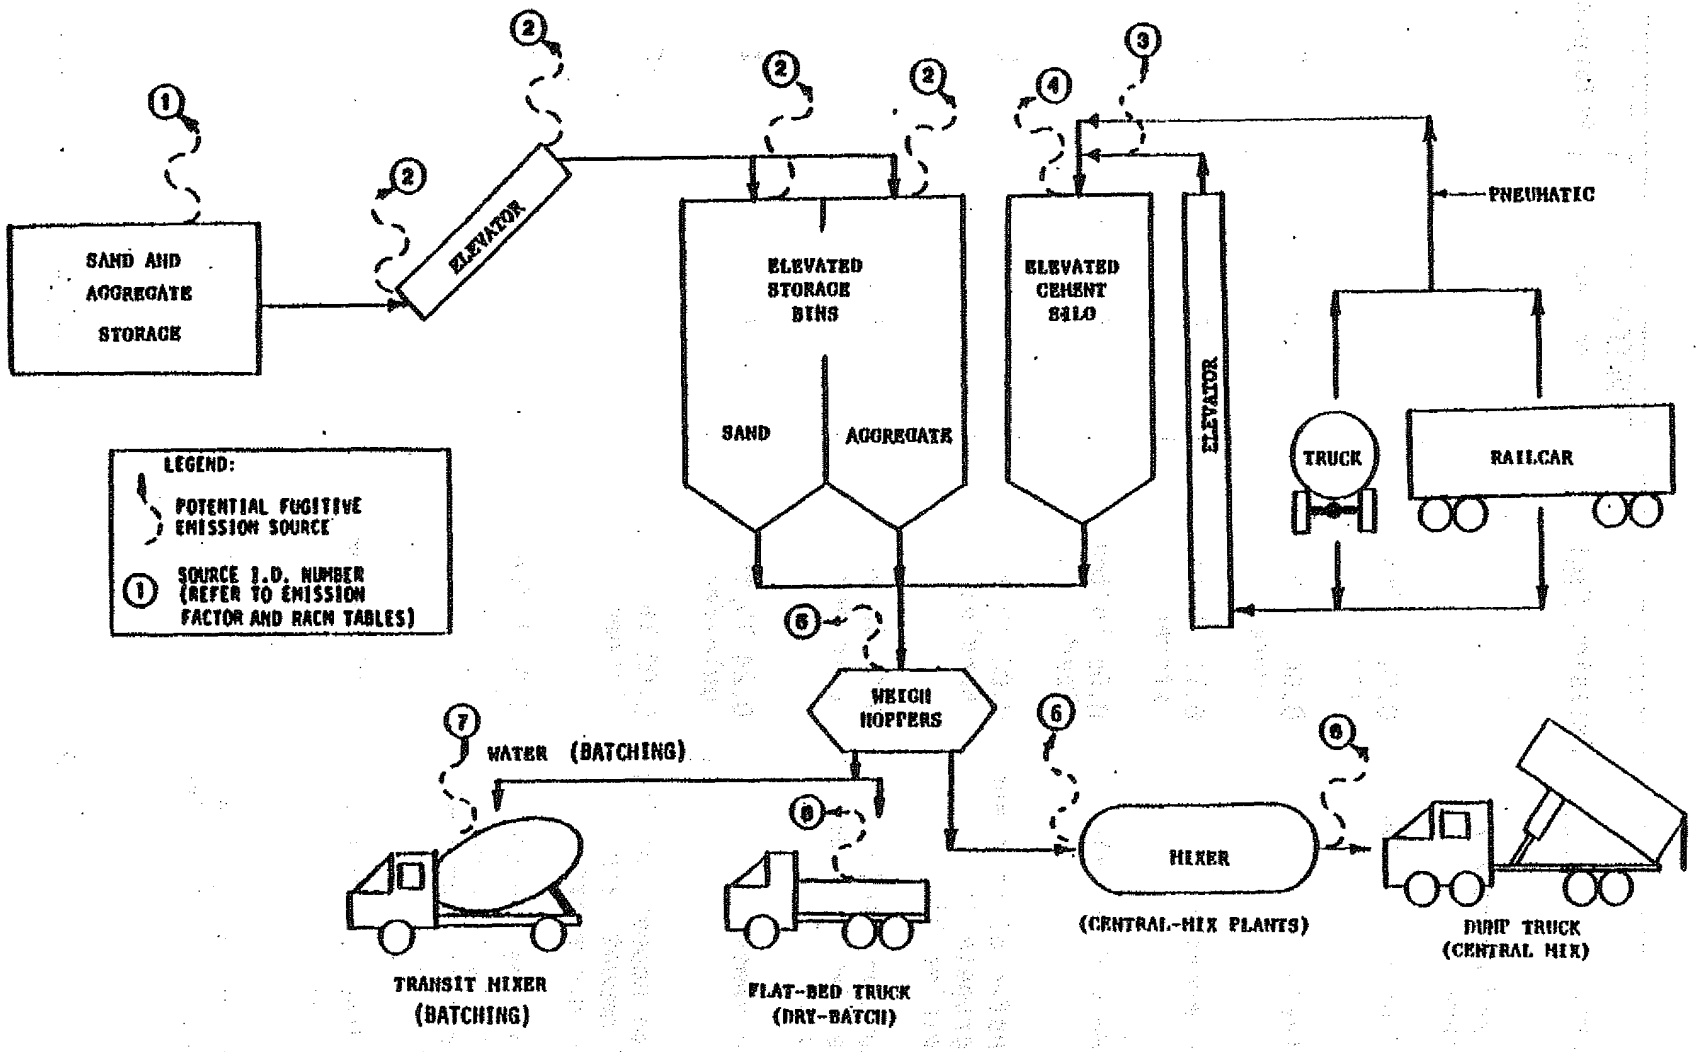

Figure 2.22-1. Simplified process flow diagram for concrete batching and associated fugitive particulate emission sources.

TABLE 2.22-1. FUGITIVE DUST EMISSION FACTORS FOR CONCRETE BATCHING PLANTS

	Source	Emission factor	Reliability rating	Reference
(1)	Sand and aggregate storage			
	loading onto piles	0.04 lb/ton loaded	D	2
	vehicular traffic	0.04 lb/ton stored	D	2
	wind erosion	0.11 lb/ton stored	D	2
	loadout from piles	0.05 lb/ton loaded	D	2
(2)	Transfer of sand and aggregate to elevated bins	0.04 lb/ton handled	E	2
(3)	Cement unloading to elevated storage silos	0.24 lb/ton unloaded	E	2
(4)	Silo vents	0.24 lb/ton unloaded	E	2
(5)	Weigh hopper loading of cement, sand and aggregate	0.02 lb/ton loaded	E	2
(6)	Mixer loading of cement, sand and aggregate (central-mix plant)	0.04 lb/ton loaded	E	2
(7)	Loading of transit-mix truck (batching plant)	0.02 lb/ton	E	2
(8)	Loading of flat-bed truck (dry-batching plant)	0.04 lb/ton	E	2

Compound	Fugitive Emission Oxide Composition, Percent By Weight For Cement Dust
Silica	18-23
Al_2O_3	3-8
Fe_2O_3	1-5
CaO	61-66
MgO	0-5
SO_3	2-4
Free Lime	0-2
Minor Compounds	0-1

The American Conference of Governmental Industrial Hygienists has established levels for which airborne chemical compounds could be tolerated without adverse effects on humans.[4] Of the above compounds, aluminum oxide, iron oxide, magnesium oxide and free lime are considered nuisance substances which can be tolerated at relatively high levels. Silica may be hazardous depending upon the amount of quartz contained in the silica. Calcium oxide can be tolerated at levels up to 5 mg/m^3.

Particle size characteristics of the dust vary according to the grades of cement. A range of 10 to 20 percent by weight of particles < 5μm in size is typical for the various grades of cement. Table 2.22-2 summarizes the particle size distribution and bulk density of three common grades of cement.[5]

Table 2.22-2. Physical Characteristics of Three Common Grades of Cement

Characteristic	Weight Percent of Cement		
Particle Size (μm)	Grade I	Grade II	Grade III
0 to 5	13.2	9.6	21.8
5 to 10	15.1	16.6	22.5
10 to 20	25.7	18.8	26.7
20 to 40	29.0	36.6	23.6
40 to 50	7.0	10.4	5.4
50 to 66	5.0	6.0	0
66 to 99	4.0	2.0	0
99 to 250	1.0	0	0
250 (60 mesh)	0	0	0
Bulk Density (lb/ft^3)	54.0	51.5	62.0

2.22.4 Control Methods

This section discusses all available control methods for the fugitive dust emission sources at concrete batching plants.

For the control of fugitive dust emissions from sand and aggregate storage piles, several control methods are available. For loading onto piles, the available control methods are stone ladders, wet suppression (chemical) and telescopic chutes. Loading out operations may be controlled by the use of wet suppression (chemical), watering and underpile conveyors which have a gravity feed to conveyors. For control of wind erosion emissions, the available control methods consist of enclosure (storage bins or silos), wet suppression (chemical) and watering. Lastly, fugitive dust generated by vehicular traffic associated with storage pile activities may be controlled by use of an enclosure, wet suppression (chemical), watering and by using traveling booms rather than vehicles to distribute material.

For control of fugitive dust emissions from plant roadways and parking areas, the reader is referred to Section 2.1.1 of this document.

The amount of fugitive dust generated during the transfer of sand and aggregate from storage to elevated storage bins depends primarily on the surface moisture content of these materials. To ensure that the material is sufficiently moist to prevent dusting, water sprays may be applied at the feed, transfer and discharge points of the belt conveyor or bucket elevator system. To prevent wind losses, most plants partially or completely enclose the conveyor system or use watering and/or chemical dust suppressants.[6] In addition, transfer points may be exhausted to fabric filters for control. Section 2.1.3 and 2.18 further discuss transfer and conveying sources in detail.

A typical cement-receiving and storage system is shown in Figure 2.22-2.[7] The receiving hopper is at or below ground level. If it is designed to fit the canvas discharge tube of the hopper truck, little or no dust is emitted at this point. After a brief, initial puff of dust, the hopper fills completely, and the cement flows from the truck without any free fall.

Cement elevators are either the vertical-screw type or the enclosed-bucket type. Because both are totally enclosed, neither emits any dust if in good condition.[8]

The cement silo must be vented to allow the air displaced by the incoming cement to escape. Unless this vent is filtered, a significant amount of dust escapes. Control can be accomplished by venting to a central dust collecting system or a single collector placed on top of each silo. A fabric type of collector is most often used to vent the cement silo. A fabric "sock", that is placed on each silo vent, can be operated without an exhaust fan when the material is delivered to the silo by bucket elevators because it is simply used to filter the small volume of air that is forced out.[9]

Pneumatic transfer of cement to elevated storage silos from trucks and railcars equipped with compressors and pneumatic delivery tubes is finding increased application over cement transfer by bucket elevator.[10] Pneumatic transfer eliminates emissions between the truck or railcar and the cement silo and requires control only at the cement silo vent by fabric filters. In plants receiving cement pneumatically, use of a fabric "sock" (filtered vent used for the gravity filling of cement) is inadequate.[11]

The volume of conveying air required in the pneumatic delivery system is about 350 cfm to 700 cfm depending on the loading cycle, etc.[12] Since the air is being forced into the silo, the baghouse will require a blower in order to relieve the pressure inside the

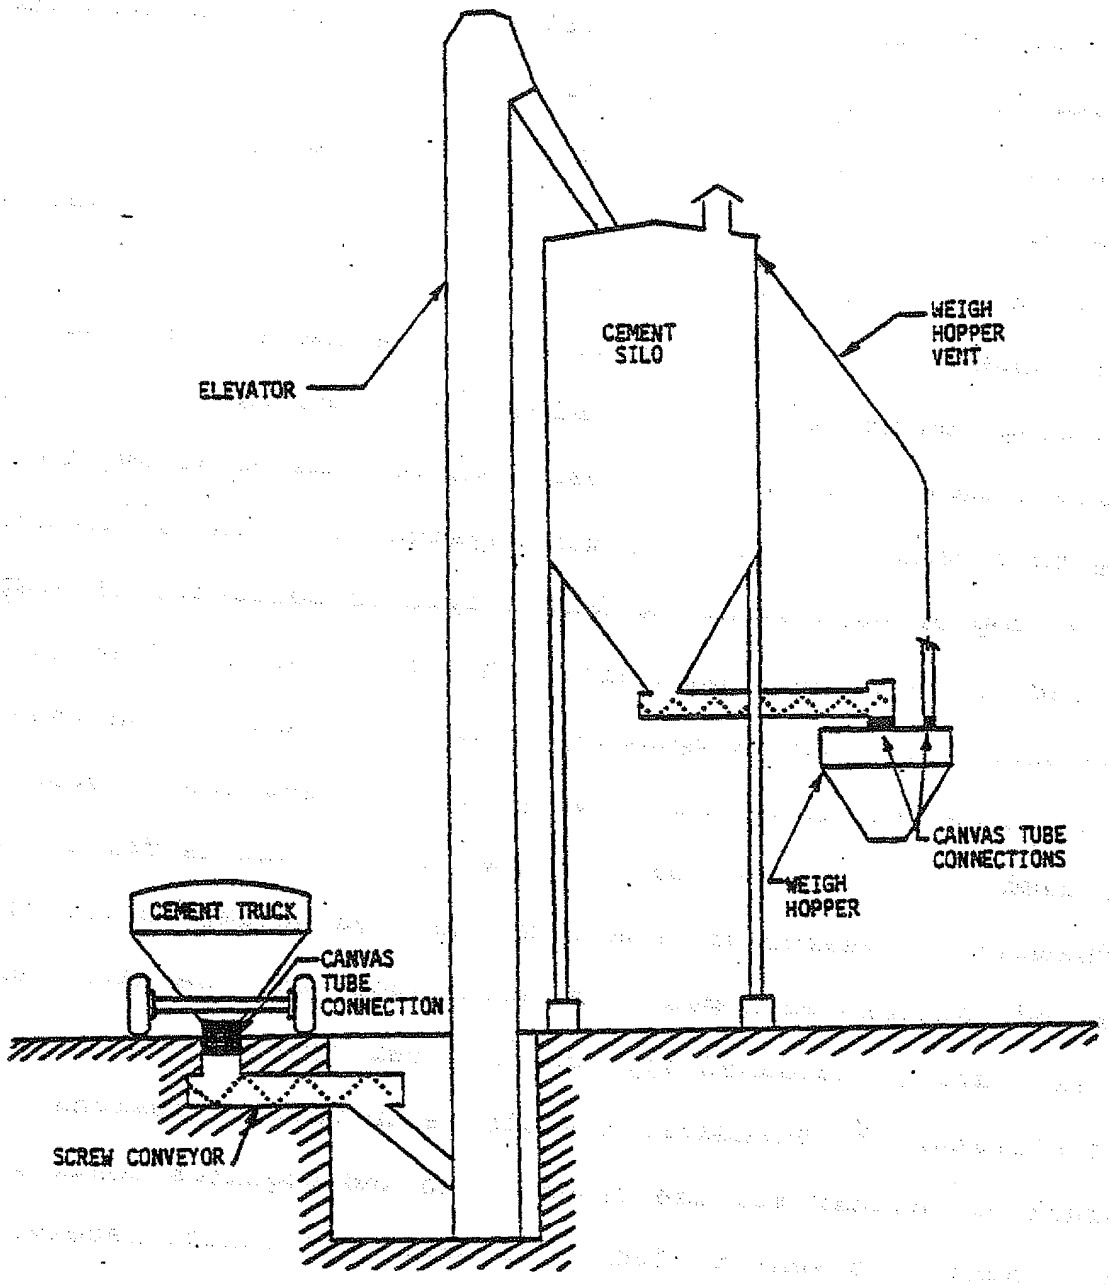

Figure 2.22-2. Cement-receiving and storage system.

silo, and allow flow through the fabric filter. A mechanical shaking mechanism also should be provided to prevent cement from blinding the filter cloth of the baghouse. A vent rate of approximately 1,200 to 1,300 cfm is generally required.[13] The negative pressure created by using a forced draft also prevents dust leakage around access doors and other openings.

Another less expensive type of control measure is to mount a bank of approximately four simple bin vent filters atop the silo. The filtering velocity should not exceed 7 cfm, giving a filter cloth area of approximately 100 square feet for the 700 cfm of air encountered at the end of the cycle. The filter design must include a shaking mechanism to prevent blinding of the filter cloth. The major disadvantage of using a bank of several simple bin vent filters as just described is the possibility of pressure build-up within the silo. If, for some reason, the filter should become blinded, there is a danger of rupturing the silo. Therefore, proper maintenance and regular inspection of the filters are essential.[14]

Where baghouses are used to control other larger cement dust sources as those existing in a dry-batching plant or in a central-mix plant, the cement silo can easily be vented to the same baghouse.[15]

The rapid discharge of sand, aggregate and cement into the weigh hopper generates emissions that may be controlled by venting the displaced air to the individual storage bins and silos or by venting it directly to a central control system.

Fugitive dust occurring from air displaced as dry materials are discharged from the weigh hopper into the mixer at a central-mix plant can be considerable. A mobile hood placed over the outlet of

the discharge end of the mixer coupled with venting to a fabric filter can accomplish effective control. When the mixer is ready to be dumped, this hydraulically operated hood is swung away from the discharge end. For a hood of this type, the indraft face velocity should be approximately 1,000-1,500 ft/min in order to adequately capture the fugitive dust.[16]

At batching plants that load transit-mix trucks, the dropping of a batch from the weigh hopper to the transit mixer can cause cement dust emissions from several points. In the loading of transit-mix trucks, a gathering hopper is usually used to control the flow of materials. Dust can be emitted from the gathering hopper, the truck-receiving hopper and the mixer. The design and location of the gathering hopper can do much to minimize dust emissions. The hopper should make a good fit with the truck-receiving hopper, and its vertical position should be adjustable. Figure 2.22-3 illustrates a design that has been successfully utilized for minimizing these dust emissions.[17] Compressed air cylinders raise and lower the gathering hopper to accommodate trucks of varying heights. A steel plate with a foam rubber backing is attached to the bottom of the gathering hopper and is lowered until it rests on the top of the truck-receiving hopper. Water for the mix is introduced through a jacket around the discharge spout of the gathering hopper and forms a dust-reducing curtain. By discharging the cement hopper into the center of the aggregate stream, and providing choke feed between the weigh hopper and the gathering hopper, dust emissions from the top of the gathering hopper can be minimized. For plants that don't have this type of gathering hopper, an enclosure or a hood vented to a baghouse and made of sheet metal which totally encloses the transit-mix truck-receiving hopper, when in place, may be used.

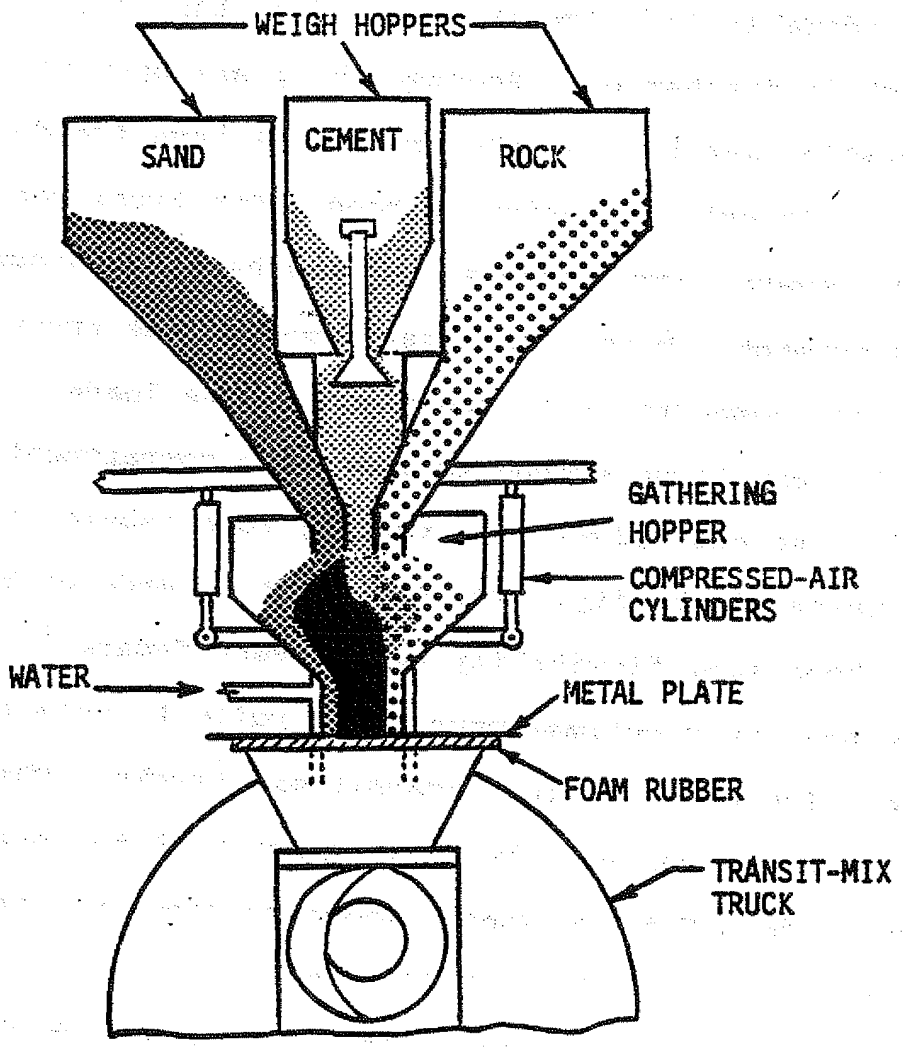

Figure 2.22-3. An adjustable gathering hopper.

Most plants that do dry-batching also do batching with transit-mix trucks; therefore, the weigh hoppers must be high enough to accommodate the transit-mix trucks. Since the receiving hopper of most transit-mix trucks is several feet higher than the top of the flat-bed trucks used to haul the materials in dry-batching, there are considerable fugitive emissions from the fall of material when a dry batch is discharged. Because the plant operator must view the operation and because the truck must have freedom of movement, this is a difficult operation to hood. The truck bed is usually divided into several compartments, and the batch is dropped into each compartment. This necessitates moving the truck after each drop so another compartment of the truck can be loaded. A canopy-type of hood, just large enough to cover one compartment at a time, provides effective dust pickup for venting to a fabric filter and affords adequate visibility. The sides can be made of heavy rubber to give the hood some flexibility and prevent damage if a truck hits it. The hood is sometimes mounted on rails to permit it to be withdrawn and allow batching into transit-mix trucks. The exhaust volume required to collect the dust varies with the shape and position of the hoods. With reasonably good hooding, the required volume is approximately 6,700 to 7,000 cfm.[18]

A conscientious housekeeping program, which includes such measures as prompt cleanup of spills, maintenance of conveying equipment to prevent leaks, and proper handling and disposal of the material collected by fabric filters, is necessary to complete the overall effective control of fugitive emissions at concrete batching plants.

Table 2.22-3 summarizes the available control techniques, their effectiveness and estimated costs, and the RACM selections.

2.22.5 Recommended Reasonably Available Control Measures (RACM)

The RACM selections for concrete batching plant fugitive sources are presented in Table 2.22-3. The recommended control for sand and aggregate stockpiling, as well as the transferring of sand and aggregate to elevated bins, is a wet dust suppression system utilizing a chemical wetting agent. This system gives good control efficiency (estimated 90%[24]) and reduces visible emissions to almost zero percent opacity.[25]

For vehicular traffic at sand and aggregate storage areas, the use of wet suppression (chemical) on unpaved storage areas is recommended. Wetting agents which are sprayed onto the material during processing or at transfer points retain their effectiveness in subsequent storage operations, because they retain surface moisture for extended periods, thereby preventing dusting.

Recommended control for cement unloading to elevated storage silos is the use of enclosures. This is feasible because most plants already control these emissions in this way.

The silo vents (pneumatic loading to silo) can be controlled either by a central control system which controls fugitive emissions from cement dust sources, such as those existing in a dry-batching plant or in a central-mix plant, or by a bank of approximately four simple bin vent filters on top of each silo. These controls are advantageous not only for their high degree of particulate control, but also for the added benefit of product recovery.

For silos which are loaded by bucket elevator, RACM is simply the use of fabric "socks". This control method is adequate for such systems because the air displaced from the silo during such loading is minimal.

Where a central collection system is not employed, the weigh hopper emissions may be controlled by venting back to the bins or silos.

TABLE 2.22-3. A SUMMARY OF THE CONTROL ALTERNATIVES, EFFICIENCIES AND COSTS, AND THE RACM SELECTIONS FOR FUGITIVE DUST EMISSIONS FROM CONCRETE BATCHING PLANTS

Fugitive dust sources	Control alternatives	Control efficiency, %	Control costs, Jan., 1980 $		Cost benefit, $/lb	RACM selection

[j]Part of central collection system to control sources 4, 5, 6, & 8 at central mix plants.

[k]Reference 27.

[l]Applicable for plants with pneumatic delivery and no central collection system. Baghouse equipped with mechanical shaking device and blower.

[m]Costs not available.

[n]Reference 22.

[o]Applicable for plants with pneumatic delivery and not utilizing a central collection system. (Bank of approximately 4 simple filtered vents atop the silo).

[p]Reference 22 and 23.

[q]Costs included within those for source 4. One central collection system to control emissions from sources 4, 5, 6, & 8.

[r]Low value, simple enclosure; high value, enclosure plus bag filter.

[s]If an adjustable gathering hopper (choke feed) is not currently being utilized. For plants using such hopper and choke feed, no additional control is required.

[t]Applicable for plants not utilizing a central collection system.

[u]Part of central collection system to control sources 4, 5, & 6.

For mixer loading of cement, sand and aggregate at central-mix plants, RACM is the use of a mobile hood with exhaust to a central fabric filter.

The emissions occurring during the loading of the transit-mix trucks (batching) can be controlled by either enclosure or by choke feeding through the use of an adjustable gathering hopper, whichever is more economically feasible for each specific plant affected.

The use of canopy-type hoods with ventilation to a fabric filter is recommended for the loading of flat-bed trucks at dry-batching plants.

2.7 IRON FOUNDRIES

2.7.1 Process Description[1-7]

Foundries produce castings for automotive parts, light and heavy machinery, pipe and a wide range of miscellaneous products. The process involves melting scrap metal and/or pig iron (crude iron in the form of blocks weighing about 100 pounds) and pouring the molten metal into prepared molds. The two major categories are "iron" foundries and "steel" foundries. Iron foundries may be further subdivided into "gray iron", "malleable iron" and "ductile iron" foundries. Both iron and steel consist primarily of elemental iron but with differing carbon content. Iron contains 2 to 4 percent carbon, and steel contains 1 percent or less. Iron formulations also incorporate various amounts of other elements. For example, silicon content is generally in the range of 2 to 3 percent in iron formulations.[8] Steel may also contain alloying elements.

Iron foundries may be further classified as either "captive" or "jobbing" foundries. A captive foundry is one that is a regular operating element of a manufacturing establishment and whose castings are generally made for the products of the parent company. In contrast, a jobbing foundry is one that manufactures a variety of castings which are not used in its own products, but are made for the products of other companies.

Figures 2.7-1 and 2.7-2 illustrate the process flow in a typical iron foundry. The basic process flow is essentially the same regardless of whether the foundry is captive or job shop. About 70 percent of the iron melted in the U.S. is produced in a cupola furnace.[9] Cupola capacities range from 1 to 100 tons of molten metal per hour. Over 60 percent operate in the range of 3 to 11 tons per hour. (Figure 2.7-3 illustrates a typical cupola furnace.) The other types of furnaces used in iron foundries are

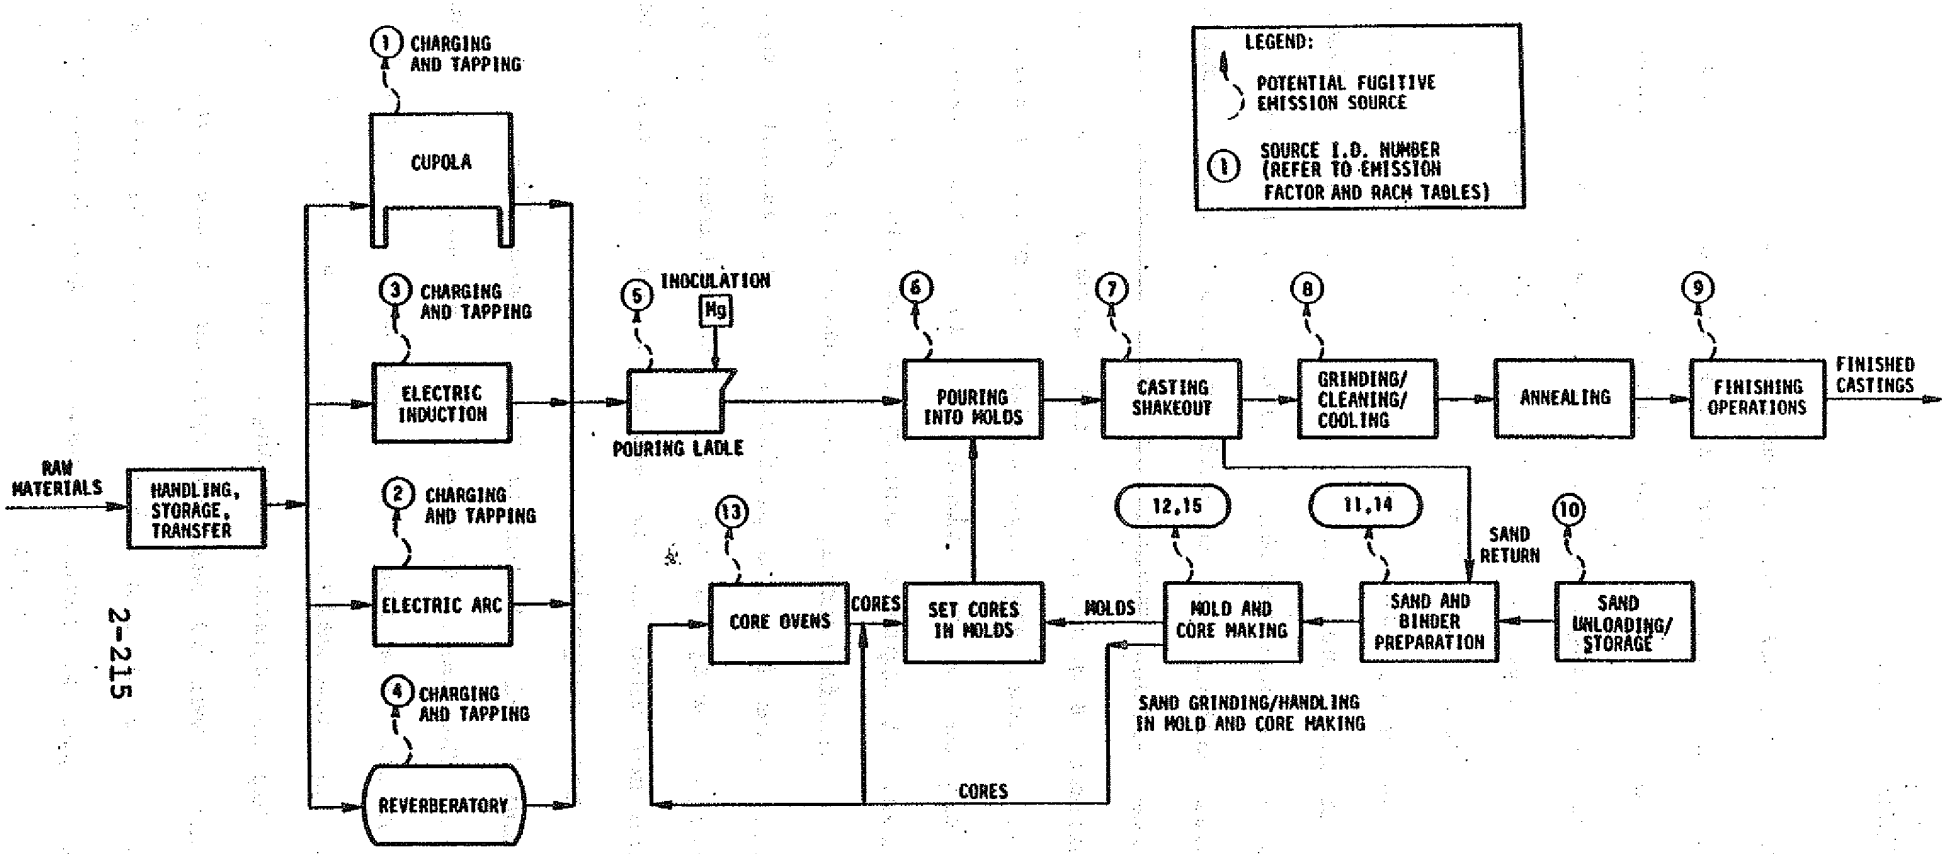

Figure 2.7-1. Simplified process flow diagram for iron foundries and associated fugitive particulate emission sources.

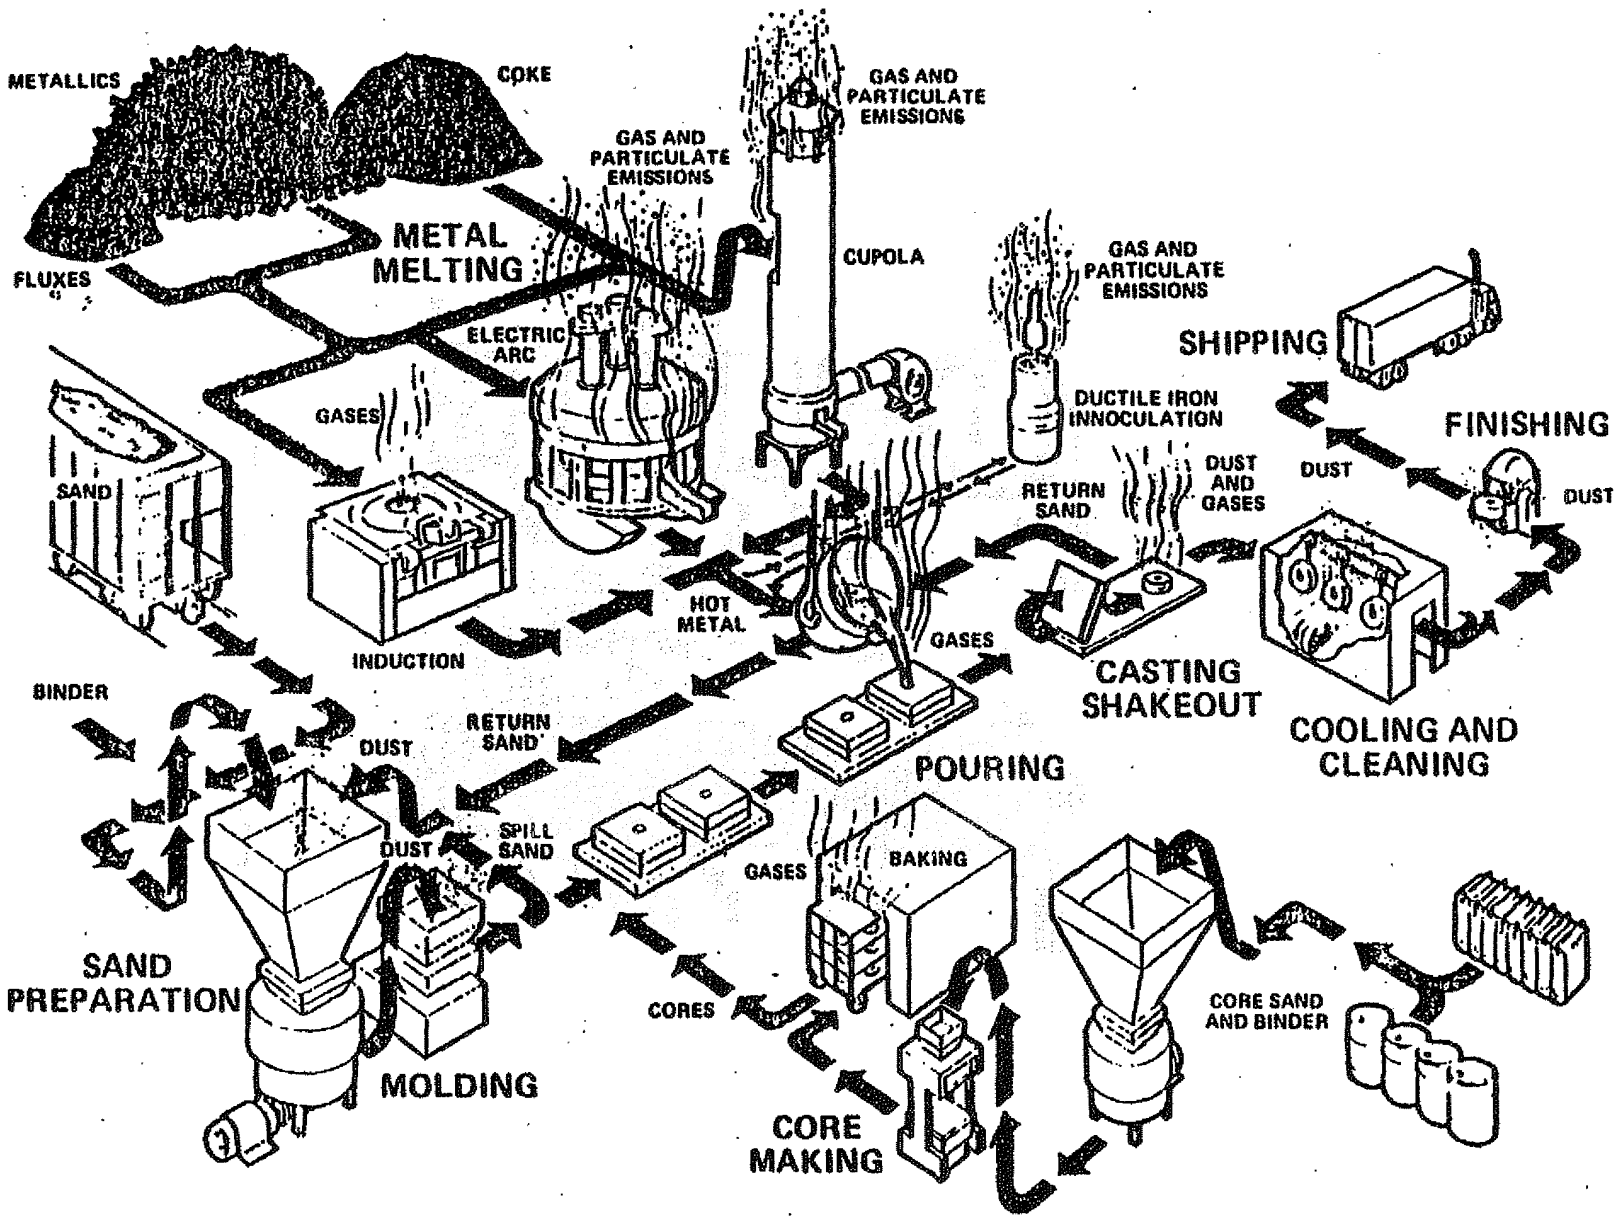

Figure 2.7-2. Iron foundry process flow diagram.[10]

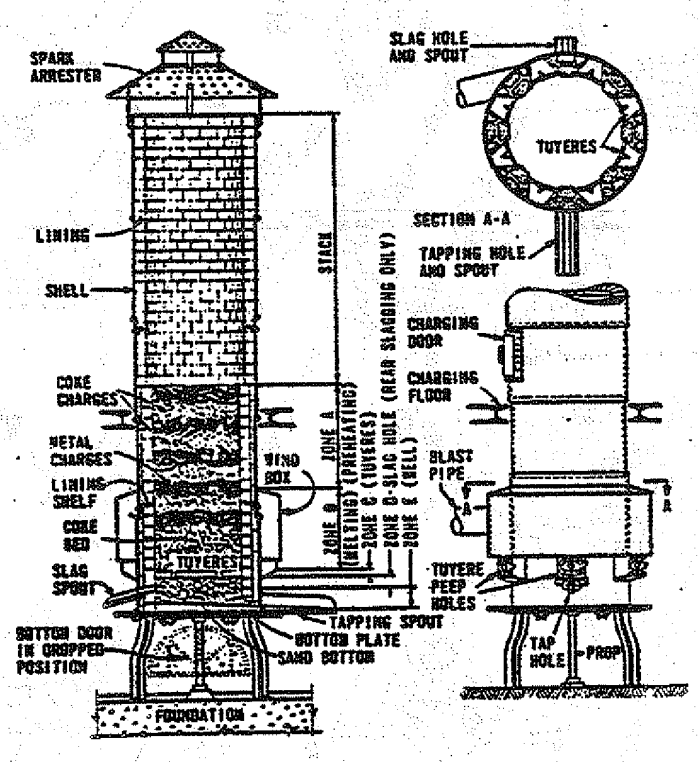

Figure 2.7-3. Cupola furnace.[11]

electric arc, electric induction and reverberatory. (These furnaces are shown in Figures 2.7-4 to 2.7-7.)

Raw materials are charged into the cupola through a door in the top of the furnace. The raw materials consist of iron and/or steel scrap, pig iron, flux materials, ferrosilicon and coke. Fluxes are limestone or similar minerals, that absorb impurities after the charge has melted. Coke is essentially pure carbon in lump form. The burning of the coke provides the heat to melt the raw materials. As the charge melts, it descends to the bottom of the furnace where the molten metal product is drained out periodically. Fresh raw materials are added to keep the furnace full. Operation of cupola furnaces can be done on a continuous basis.

The charge for electic arc, electric induction and reverberatory furnaces consists mainly of iron and/or steel scrap, pig iron and limestone. The reverberatory furnace is heated by firing gas or oil. These furnaces are operated on a batch basis.

The molten metal is tapped from the furnace at a temperature of about 2900°F into a ladle or into a holding furnace until it is ready to be drained into a ladle. The ladle is transported to the mold line, and molten metal is poured into prepared molds. The molds contain the molten iron within the mold form until it solidifies. In production of high strength ("ductile iron") castings, magnesium is added to the molten iron by a process called inoculation. (See Figure 2.7-8 for an illustration of the magnesium treatment methods used to produce ductile iron.) After solidification, the sand molds and castings are separated, and the sand is recycled to the mold making operation. Castings are shaken out of the molds, or the molds are broken away from the castings. When sufficiently

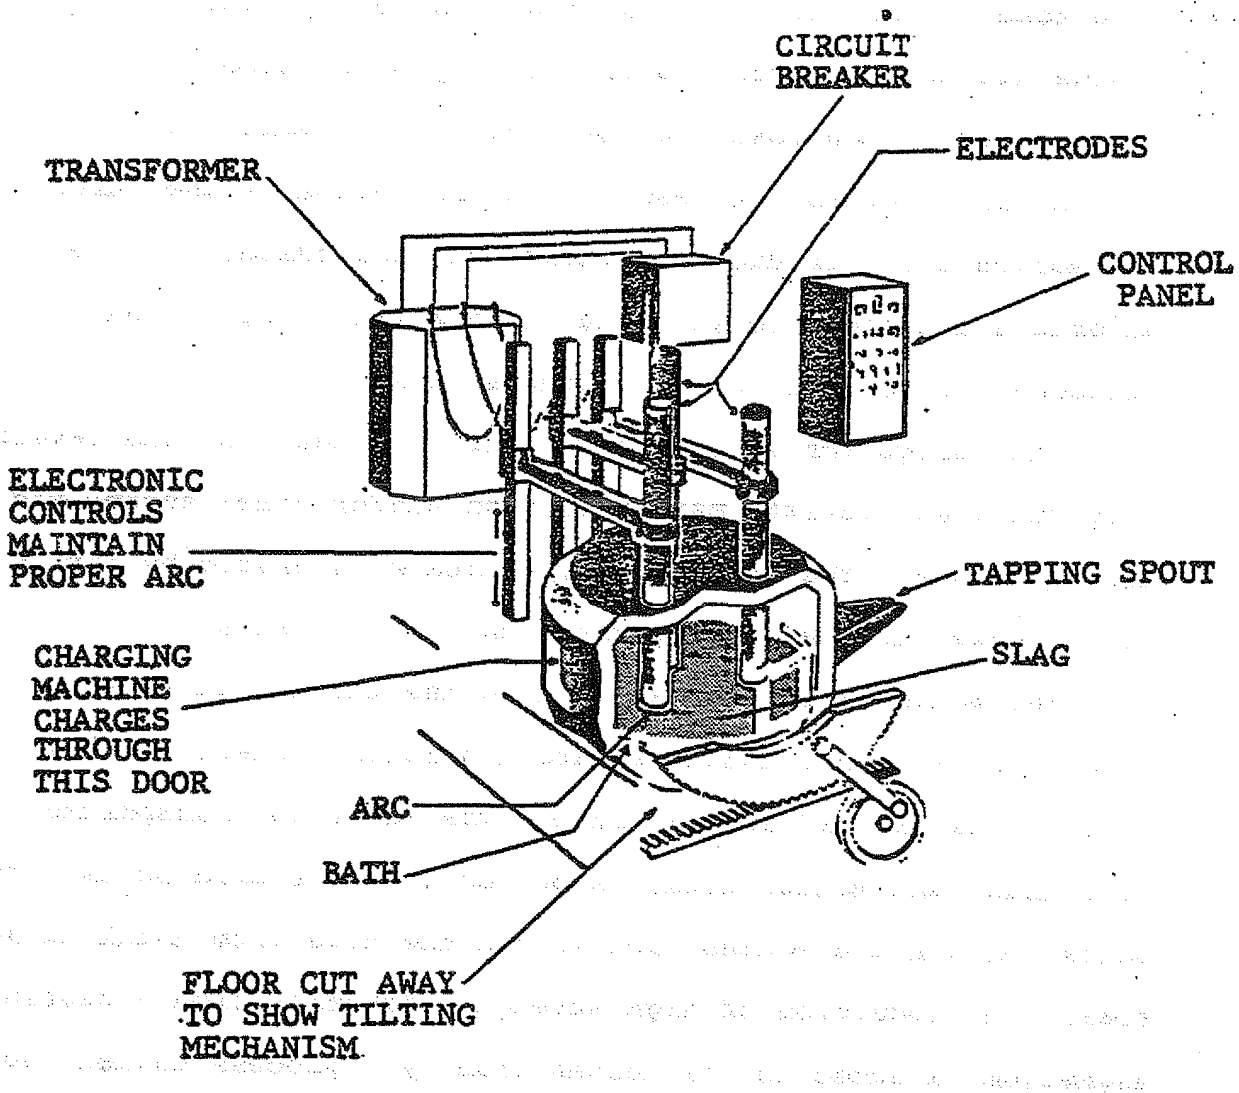

Figure 2.7-4. Electric arc furnace.[12]

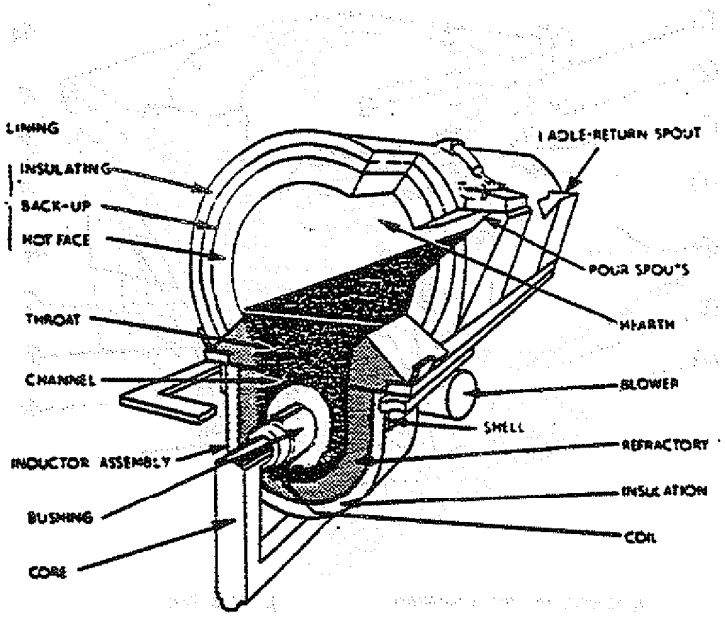

Figure 2.7-5. Channel electric induction furnace.[13]

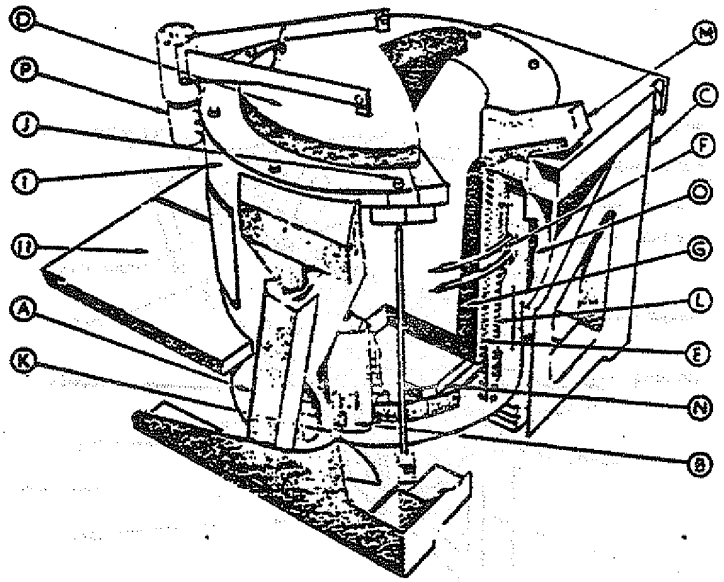

Figure 2.7-6. Coreless electric induction furnace.[14]

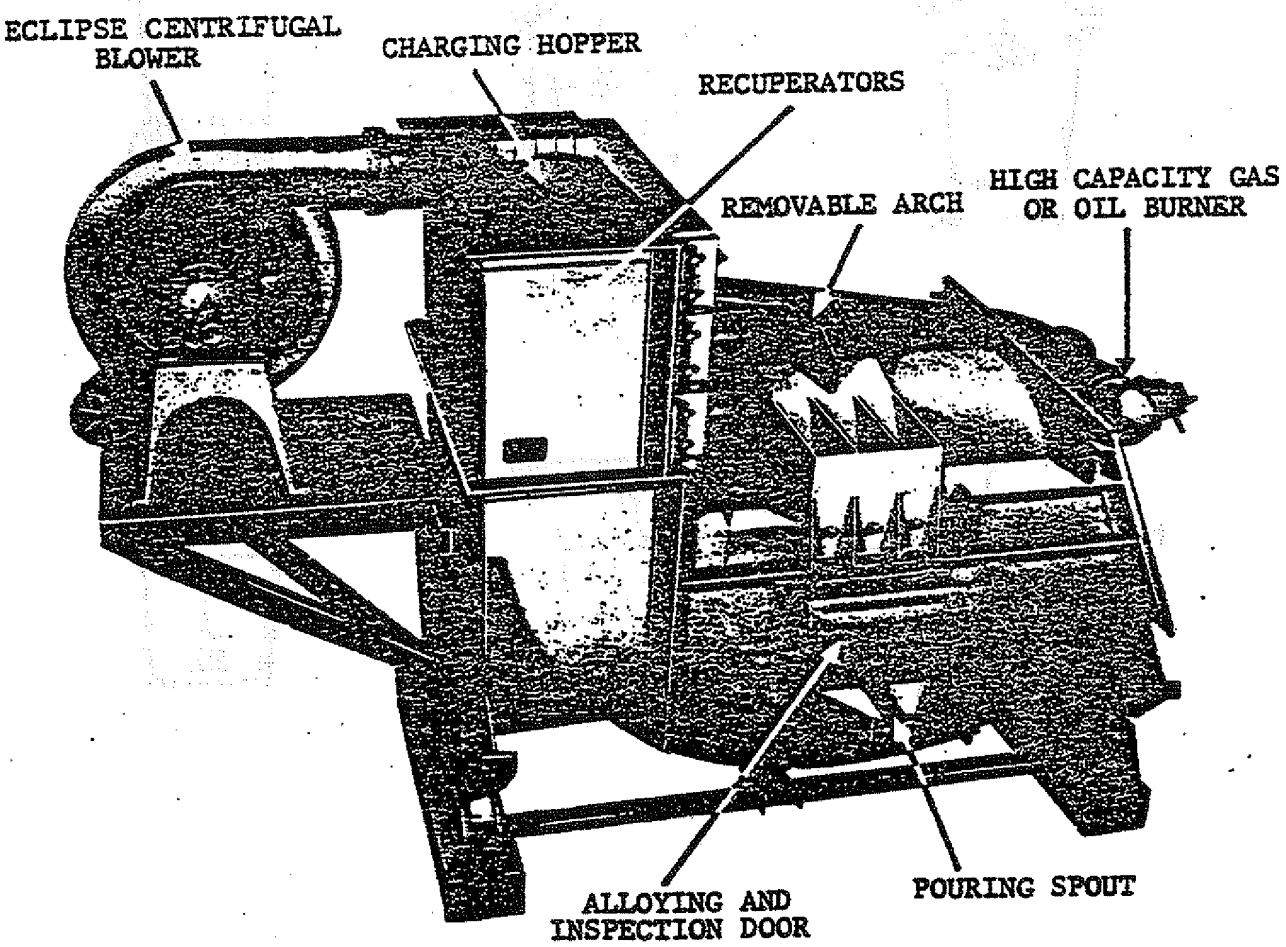

Figure 2.7-7. Reverberatory furnace.[15]

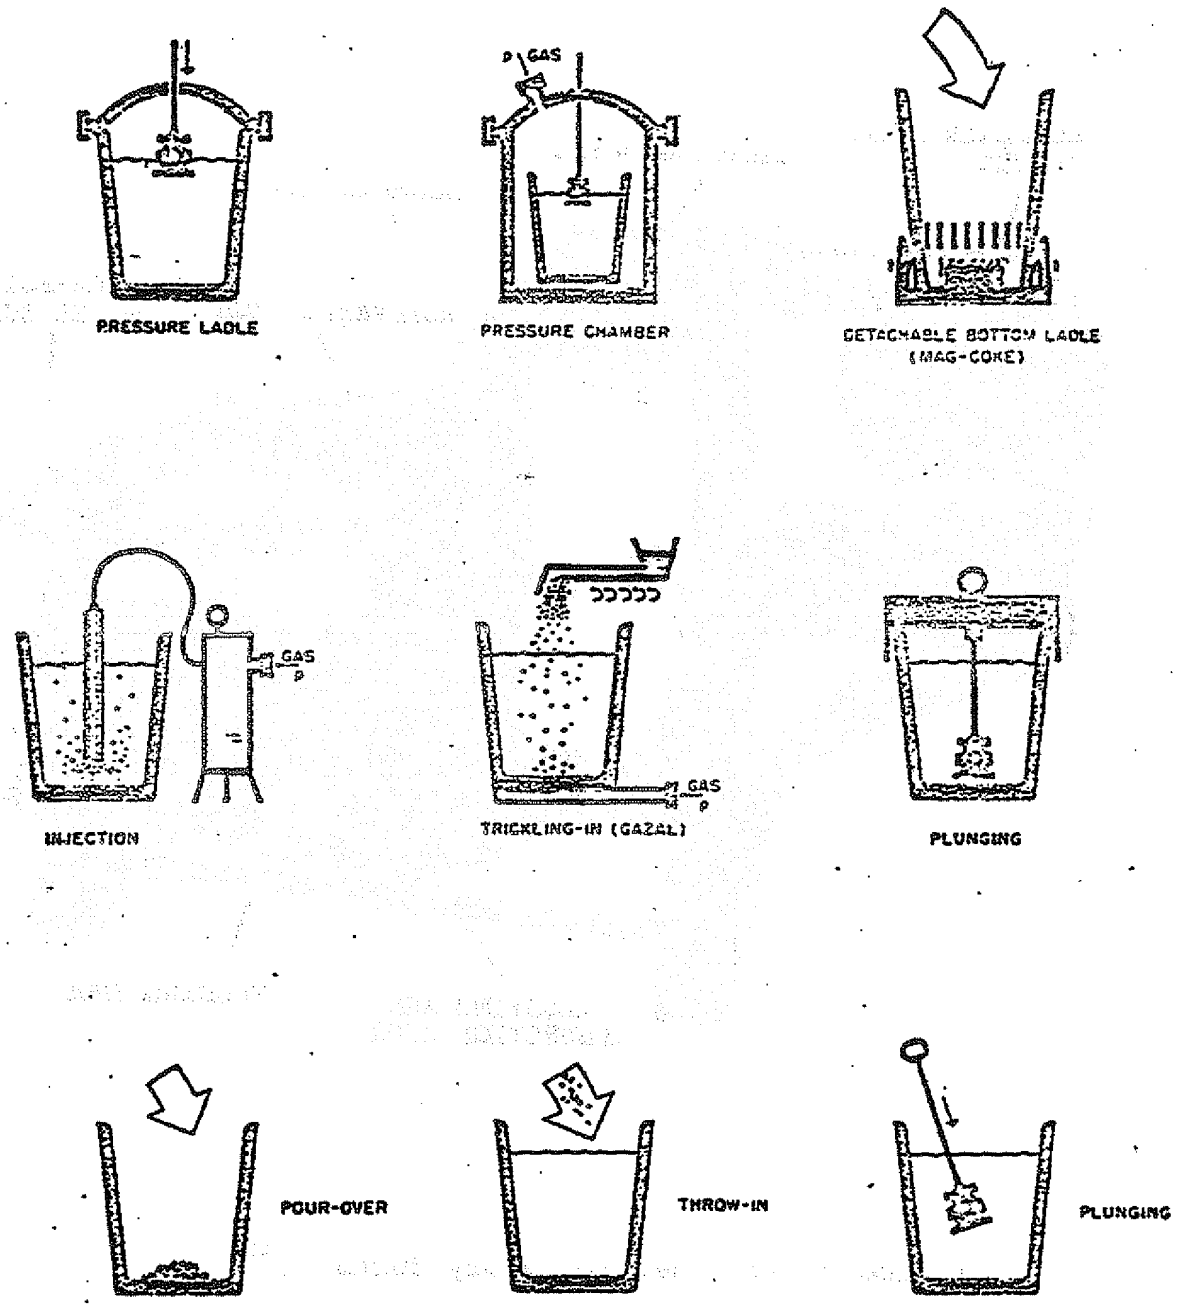

Figure 2.7-8. Magnesium treatment methods for producing ductile iron.[16]

cool, the castings are cleaned by shot blasting, and the remaining excess metal (gates, sprue, risers, flash, etc.) is removed by sawing, grinding, chipping, cutting, etc. These processes are generally housed in an enclosure.

Castings intended for certain uses may be annealed (heat treated) for several hours at temperatures of 1000 to 1600°F. Heat treating furnaces, fired by gas, oil or electricity, are referred to by such names as "annealing", "hardening", "car-bottom" and "traveling hearth" furnaces. Castings that have been annealed in the present of sufficient silicon are referred to as malleable iron castings. Some ductile iron castings, which are produced by inoculating the melt with a small amount of magnesium just prior to casting, are also often subjected to annealing. Finishing operations such as shot or sand blasting, grinding and surface coating may follow the heat treatment.

Production of molds and cores is an integral part of the foundry operation. A mold is made of sand mixed in a muller (see Figure 2.7-9) with water and binders, such as clay or resins. Pitch is sometimes added to the mold mixture primarily to prevent surface defects on the castings. A core is a separable part of the mold used to form a cavity in the casting. Cores are also made of sand and binders. Cores may be produced by any one of a number of processes including hot box, cold box, air set, shell and oil-sand methods.[17] In the oil-sand process, after the cores are formed in the desired shape, they are cured either in a baking oven (core oven) at 300-500°F or at room temperature. Curing evaporates moisture and hardens the sand mixture. Core ovens are fired with gas or oil.

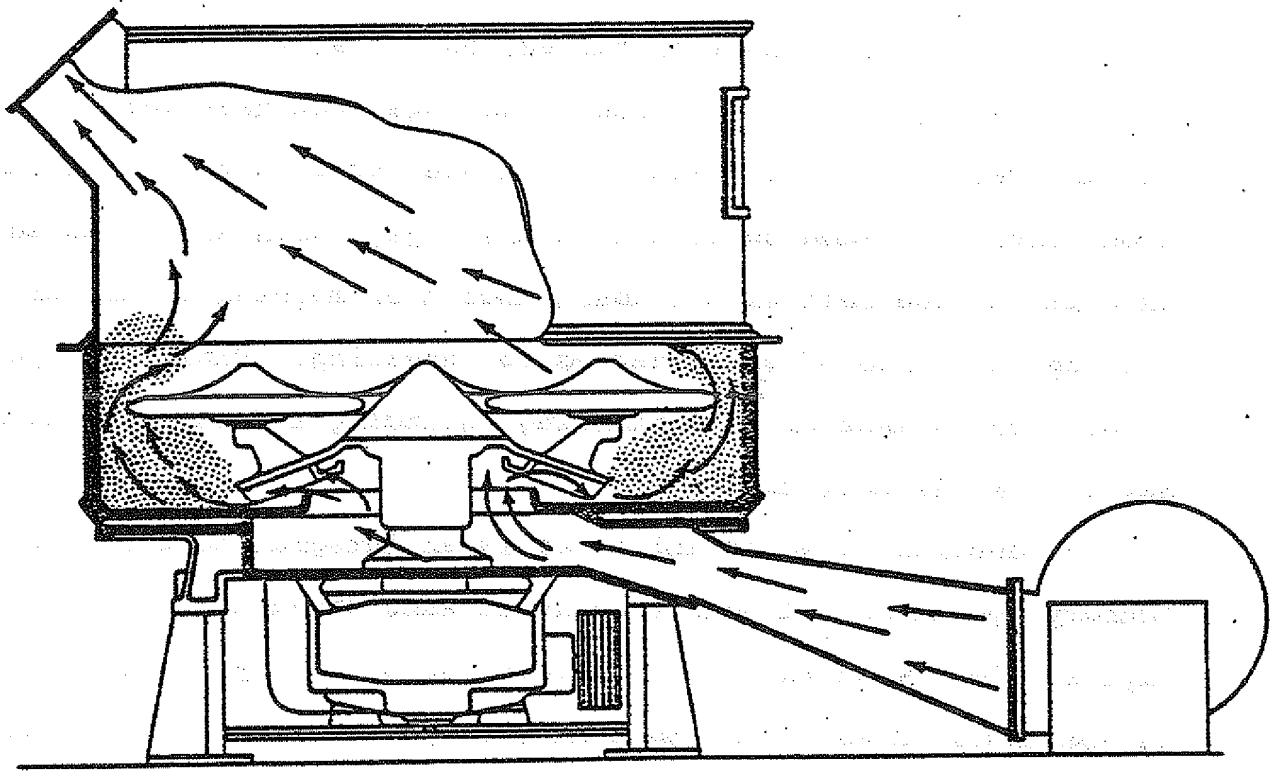

Figure 2.7-9. Sand muller.[18]

The potential sources of fugitive emissions in iron foundries include raw material receiving, storage and handling, melting furnace charging and tapping, iron inoculation, molten iron transporting and pouring, casting, shakeout, cooling, cleaning and finishing, and core and mold making. Each of these sources is identified in Figures 2.7-1 and 2.7-2.

2.7.2 Fugitive Dust Emission Factors

The estimated emission factors for iron foundry fugitive particulate sources are summarized in Table 2.7-1. Most of these emissions factors are based on "engineering judgment" (source's terminology) and very sparse test data. They should be considered of poor reliability. Emission factors were not included for coke handling and storage at iron foundries. These factors are discussed in Section 2.2.2-2. Factors are also not included for raw material handling, storage and transfer operations due to a lack of data. These sources are deemed to be insignificant as far as steel/iron scrap is concerned.

The emission factors for charging and tapping of the various furnace types, with the exception of electric induction furnaces, were derived by assuming a percentage of total furnace emissions. The emission factor for electric induction furnaces represents total furnace emissions including charging and tapping emissions. No test data were available; and, therefore, these factors are unconfirmed and have a very poor reliability rating.

The other emission factors are based upon very sparse test data and the source's engineering judgment. The reliability rating for these factors is also very poor.

TABLE 2.7-1. FUGITIVE DUST EMISSION FACTORS FOR IRON FOUNDRIES

	Source	Emission factor	Reliability Rating	Reference
1	Cupola furnace charging and tapping	0.1 to 2.0 lb/ton iron produced	E	1
2	Electric arc furnace charging and tapping	0.7 lb/ton iron charged[a] 1.4 lbs/ton iron charged[b]	E	19
3	Electric induction furnace melting, charging and tapping	1.5 lb/ton iron produced	E	1
4	Reverberatory furnace charging and tapping	0.1 lb/ton iron produced	E	3
5	Ductile iron inoculation	3.3 to 4.5 lb/ton iron produced	D	4,5
6	Pouring molten metal into molds	0.1 to 4.13 lb/ton iron produced	D	4,6
7	Casting shakeout	1.2 to 12.8 lb/ton iron produced	E	4,7
8	Cooling and cleaning castings	0.16 to 0.8 lb/ton castings produced	D	4,7
9	Finishing castings	0.01 lb/ton castings produced	E	7
10	Core and mold sand unloading and storage: mechanical handling pneumatic handling	 0.03 lb/ton sand unloaded[c] NA	 E	 20
11	Core sand and binder mixing	0.3 lb/ton sand mixed or 0.75 to 8.24 lb/ton iron produced	E E	2 4,7
12	Core making	0.35 lb/ton cores produced	E	2
13	Core baking	0.03 to 5.4 lb/ton cores baked	E	7,9,20
14	Mold sand preparation	1.3 lb/ton castings produced	E	4
15	Mold making	0.04 lb/ton castings produced	E	7

NA = Not available
[a]With no alloying in the ladle.
[b]With alloying in the ladle.
[c]Sand unloading emission factor is assumed to be equivalent to the taconite pellets unloading emission factor as presented in Section 2.1.3. Fugitive dust emissions from storage are estimated to be negligible since sand is normally stored indoors.

2.7.2 Particle Characterization[21]

The composition and particle size of dusts from various foundry operations will vary considerably. For example, dusts from a casting shakeout are mostly very fine carbonaceous material. On the other hand, dust from the grinding of castings contains coarse, freshly fractured particles, along with elemental iron, iron oxide and sand particles. Table 2.7-2 indicates the characteristics and sources of emissions in various foundry operations.

Much of the information available on particle characteristics is for the stack (non-fugitive) emissions from cupola and electric arc furnaces. However, since such information may be of value in approximating the particle characteristics of fugitive dust emission sources such as furnace charging, tapping and leaks, it is presented in this section.

The range of chemical composition of stack emission components in cupola dust has been reported in the literature as shown in Table 2.7-3. Table 2.7-3 indicates that oxides of iron and silicon and combustible materials form a high proportion of cupola dust.

Particle size distribution studies have been performed for stack emissions from cupola furnaces. The data reported in two major studies is shown in Tables 2.7-4 and 2.7-5. There is very little information in the literature on whether or not a relationship exists between particle size distribution and chemical composition of cupola emissions. One source conjectures that a high percentage of less than 5 micron particles is generally observed with substantial percentages of metallic oxides. On the other hand, a high percentage of greater than 4.4 micron particles corresponds to significant amounts of silicon oxides from foundry returns, dirty scrap and combustible materials.[27]

TABLE 2.7-2. PARTICULATE EMISSION CHARACTERISTICS FOR VARIOUS FOUNDRY OPERATIONS[22]

FOUNDRY OPERATION	TYPE	PARTICLE SIZE (μm)

Chemical composition or particulate emissions from electric arc furnaces at three iron foundries has been reported in one literature source and is shown in Table 2.7-6. The main components in these emissions were iron oxide and silicon dioxide, while substantial amounts of oxides of manganese, aluminum and magnesium were found. The emissions consist almost entirely of the oxides of various metals charged, with lesser amounts of furnace refractories and fluxing materials which were used.[28]

TABLE 2.7-6. CHEMICAL ANALYSIS OF PARTICULATE EMISSIONS FROM AN ELECTRIC ARC FURNACE[26]

Constituent	Proportion of Total Particulate, Weight Percent		
	Foundry A	Foundry B	Foundry C
Iron oxide	75-85	75-85	75-85
Silicon dioxide	10	10	10
Magnesium oxide	2	0.8	1
Manganese oxide	2	2	2
Lead oxide	1	2	0.5
Alumina	0.5	1	0.5
Calcium oxide	0.3	0.2	0.8
Zinc oxide	0.2	2	0.3
Copper oxide	0.04	0.03	0.01
Lithium oxide	0.03	0.03	0.03
Tin oxide	0.03	0.3	0.02
Nickel oxide	0.02	0.03	0.01
Chromium oxide	0.02	0.07	0.01
Barium oxide	0.02	0.07	0.01

Particle size distributions of particulate emissions have also been determined for electric arc furnaces at three foundries. These distributions are shown in Table 2.7-7. It is reported that particulate emissions from electric arc furnace melting and refining are quite small in diameter. Table 2.7-7, which indicates that 80 percent of the emissions have a particle diameter smaller than 5 microns, confirms this conclusion. A second literature reference indicates that 90 to 95 percent of the fumes from electric arc furnaces are below 0.5 microns in size.[29] Another literature source reports that 75 percent of the particulates are less than 5 microns in diameter with a mass median diameter between 2.27 and 2.33 μm.[30]

TABLE 2.7-7. PARTICLE-SIZE DISTRIBUTION FOR PARTICULATE EMISSIONS FROM THREE ELECTRIC-ARC-FURNACE INSTALLATIONS[31]

Particle Size (μm)	Cumulative Percent by Weight for Indicated Particle Diameter

< 10	41	89	91
< 15	55	93	94
< 20	68	96	96
< 50	98	99	99

The chemical composition and particle size distributions of particulate emissions from both cupolas and electric arc furnaces are highly variable and are dependent on a number of factors. One literature source concludes that the type of cupola emissions are more affected by the quantity and quality of charge materials, and that the nature and cleanliness of the charged materials are the most important factors in determining the type of emission from electric arc furnaces.[32]

2.7.4 Control Methods

Raw material handling, storage and transfer operations as such are not addressed here but are discussed in Section 2.2 for coke and limestone. These operations for the iron and steel scrap are assumed to be low emission sources, and no control is recommended.

Reduction of emissions from melting operations is enhanced when clean scrap is used in the raw charge. Clean materials that are essentially devoid of dirt, oil or grease carry no extraneous burden into and through the furnace. Use of clean scrap, or the pre-cleaning of dirty scrap before use, are useful and appropriate measures worthy of consideration and adjunctive to and supportive of other control measures. However, it has been reported that the pre-cleaning of dirty scrap is not economically feasible.[33]

Charging and tapping emissions from the cupola may be controlled by hooding the charging and tapping areas and venting the system to fabric filters or scrubbers. Another system that may be used is building evacuation and venting to a fabric filter. Proper sizing of the primary control system to maintain continuous draft through the charging door will help alleviate fugitive emissions.[13] Cupolas with above or below charge takeoffs can maintain a strong in-draft through the charge door and eliminate the escape of fugitive emissions.

Typical control devices used for electric arc or electric induction furnaces include a localized, fixed capture hood and a fabric filter or wet scrubber. The design air volume required to ventilate an electric arc furnace with an integral hood is approximately 2,500 cfm per ton of charge.[7,34] This level of ventilation should provide effective capture of charging and tapping emissions.

Newer furnaces can utilize the above system, canopy hoods (roof mounted hoods) or direct shell evacuation.[30] The latter two control measures may not be feasible on older furnaces due to space and design constraints.

Generally, control measures for charging, melting and tapping emissions from reverberatory furnaces have not been required because of their relatively low emission rates.[35] However, collection of charging and tapping emissions, as well as furnace emissions (if no stack discharge) is technically feasible thru the use of localized hooding or building evacuation with exhaust to a fabric filter or electrostatic precipitator. Such control measures may have to be implemented especially for reverberatory furnaces that are or will be using pulverized coal.

Technically feasible methods for capturing fugitive dusts from all furnace operations include building evacuation or local exhaust systems. (See Figures 2.7-10 and 2.7-11 for examples.) Building evacuation to a collection device can control emissions from all sources in a foundry such as casting shakeout, cooling, cleaning and finishing. (One source reports that the use of building evacuation or general dilution ventilation systems without separate primary emission capture is unlikely to provide a sufficient degree of control for airborne contaminants in most foundries to meet OSHA's permissible exposure limits for such contaminants.[33]) On the other hand, local exhaust control systems generally serve specific sources. Because of the large exhaust volumes and attendant high operating and capital costs for total building evacuation systems, the local exhaust methods are usually favored.

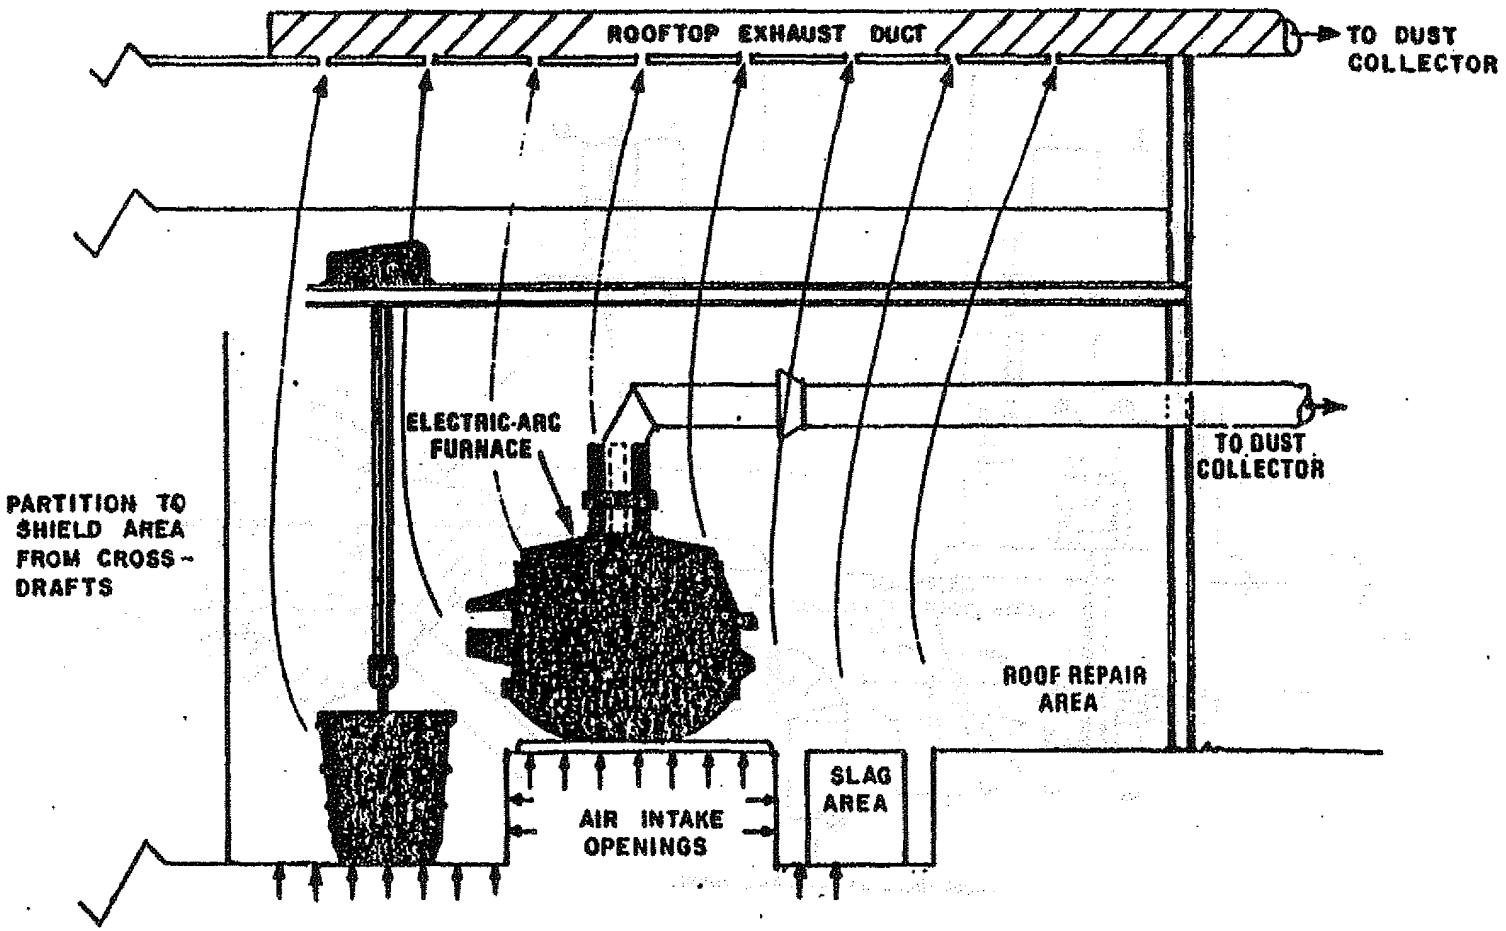

Figure 2.7-10. Building evacuation system.[36]

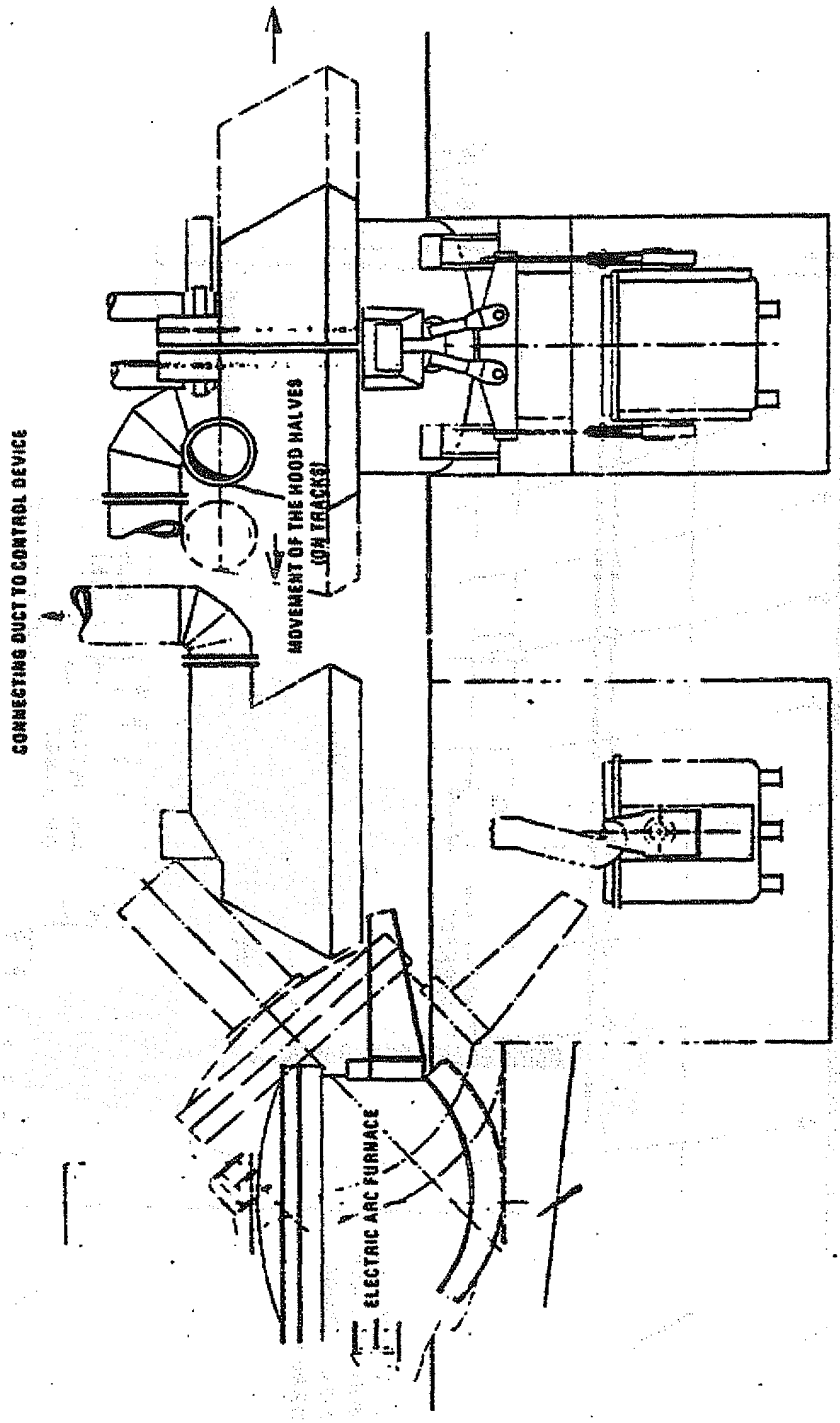

Figure 2.7-11. Mobile tapping hoods.[37]

In recent years, ductile iron inoculation stations have been equipped with collecting hoods or have been installed in enclosed rooms. The evolved gases are exhausted to a dust collection unit. Medium energy wet scrubbers and fabric filters have been used for dust collection.[38]

A side draft hood is often provided for the pouring area, and the mold cooling conveyor between the pouring and shakeout areas is often fully hooded with sheet metal. Also, the use of hooding as illustrated in Figure 2.7-12 is another successful system for capturing emissions from pouring and mold cooling. In this system, air is blown downward from the upper edge of the hood along with the pouring and mold cooling emissions. A variation of this system consists of utilizing an incoming draft from a floor grating rather than from the front edge of the hood. For smaller foundries, a movable pouring hood as shown in Figure 2.7-13 may be effective.[40] In practice, pouring and mold cooling emissions, especially for smaller production and jobbing foundries with non-fixed pouring and cooling locations, are usually exhausted directly to the atmosphere without control.[41] If control measures are deemed necessary, the hoods may be vented to wet scrubbers.

Fugitive dust emissions from the shakeout area are usually collected via a side or bottom draft hood or a partial enclosure. Duct systems from the shakeout usually lead to a single control device, frequently a wet scrubber or fabric filter. Figure 2.7-14 illustrates a shakeout with an enclosure vented to a wet scrubber.

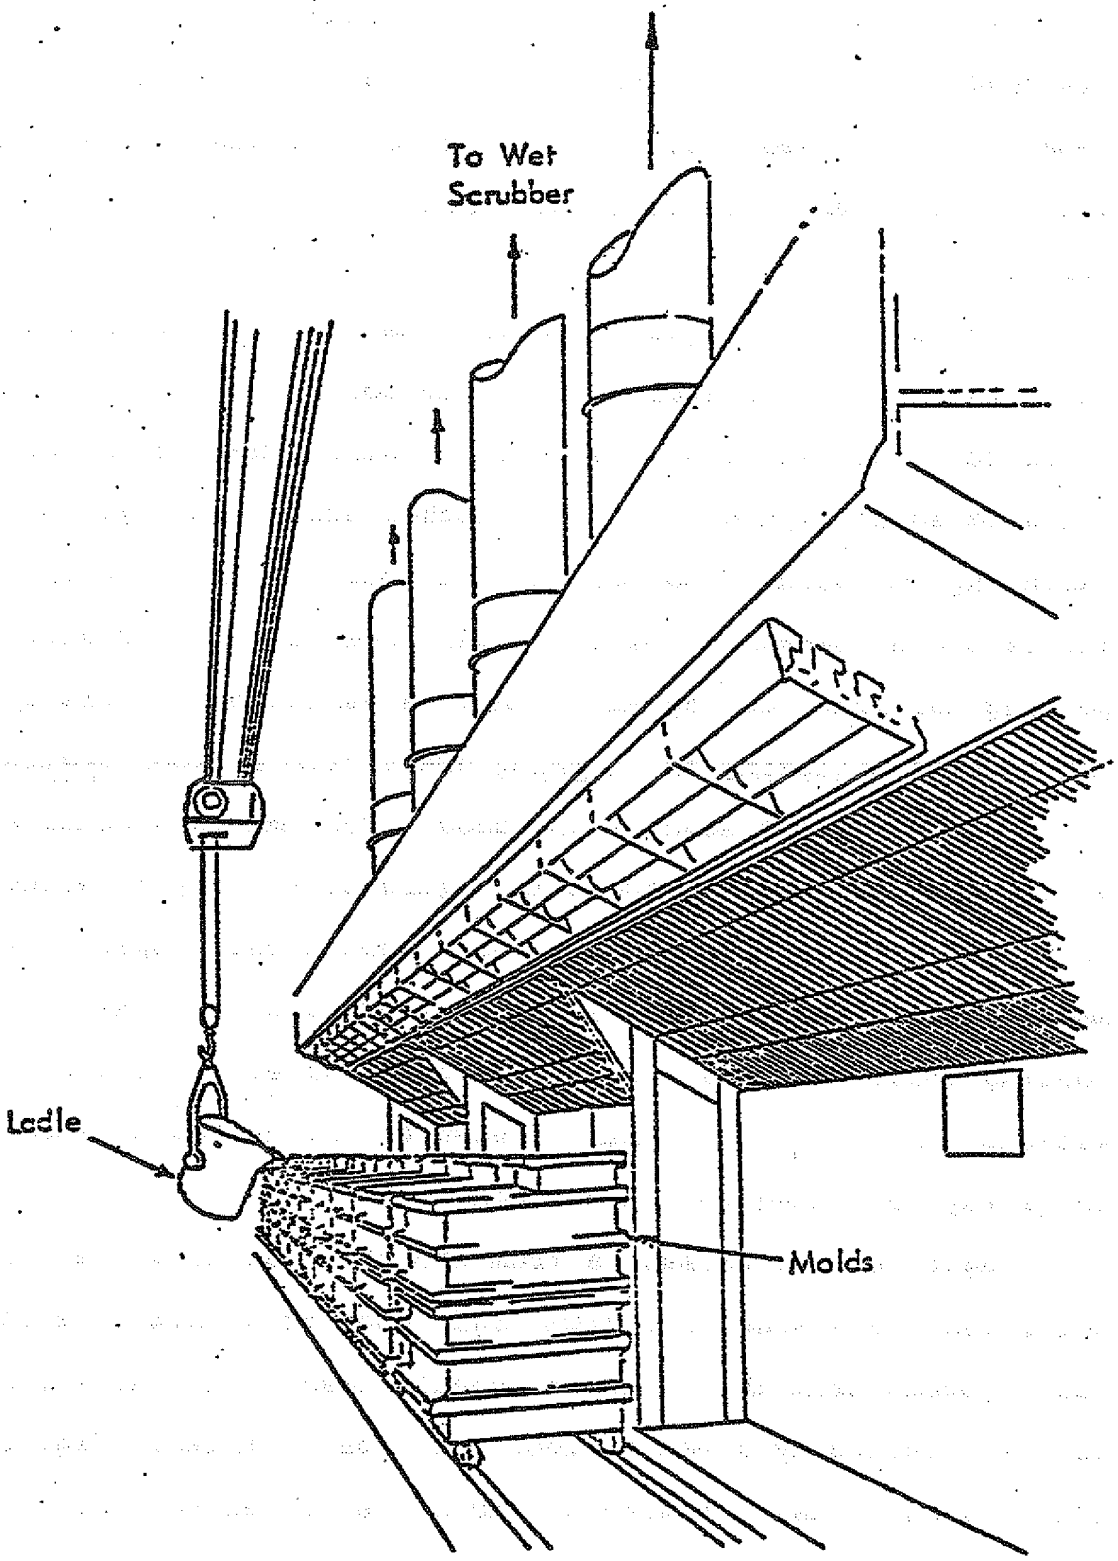

Figure 2.7-12. Hooded pouring station.[39]

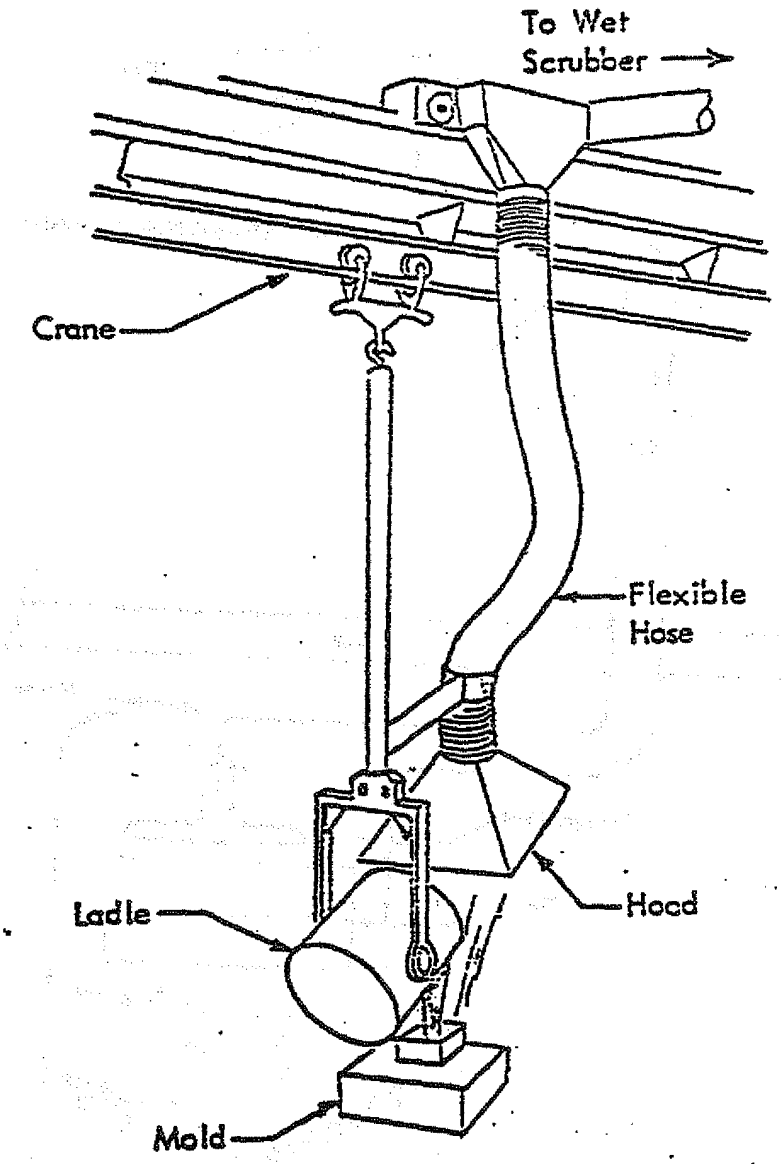

Figure 2.7-13. Movable pouring hood.[42]

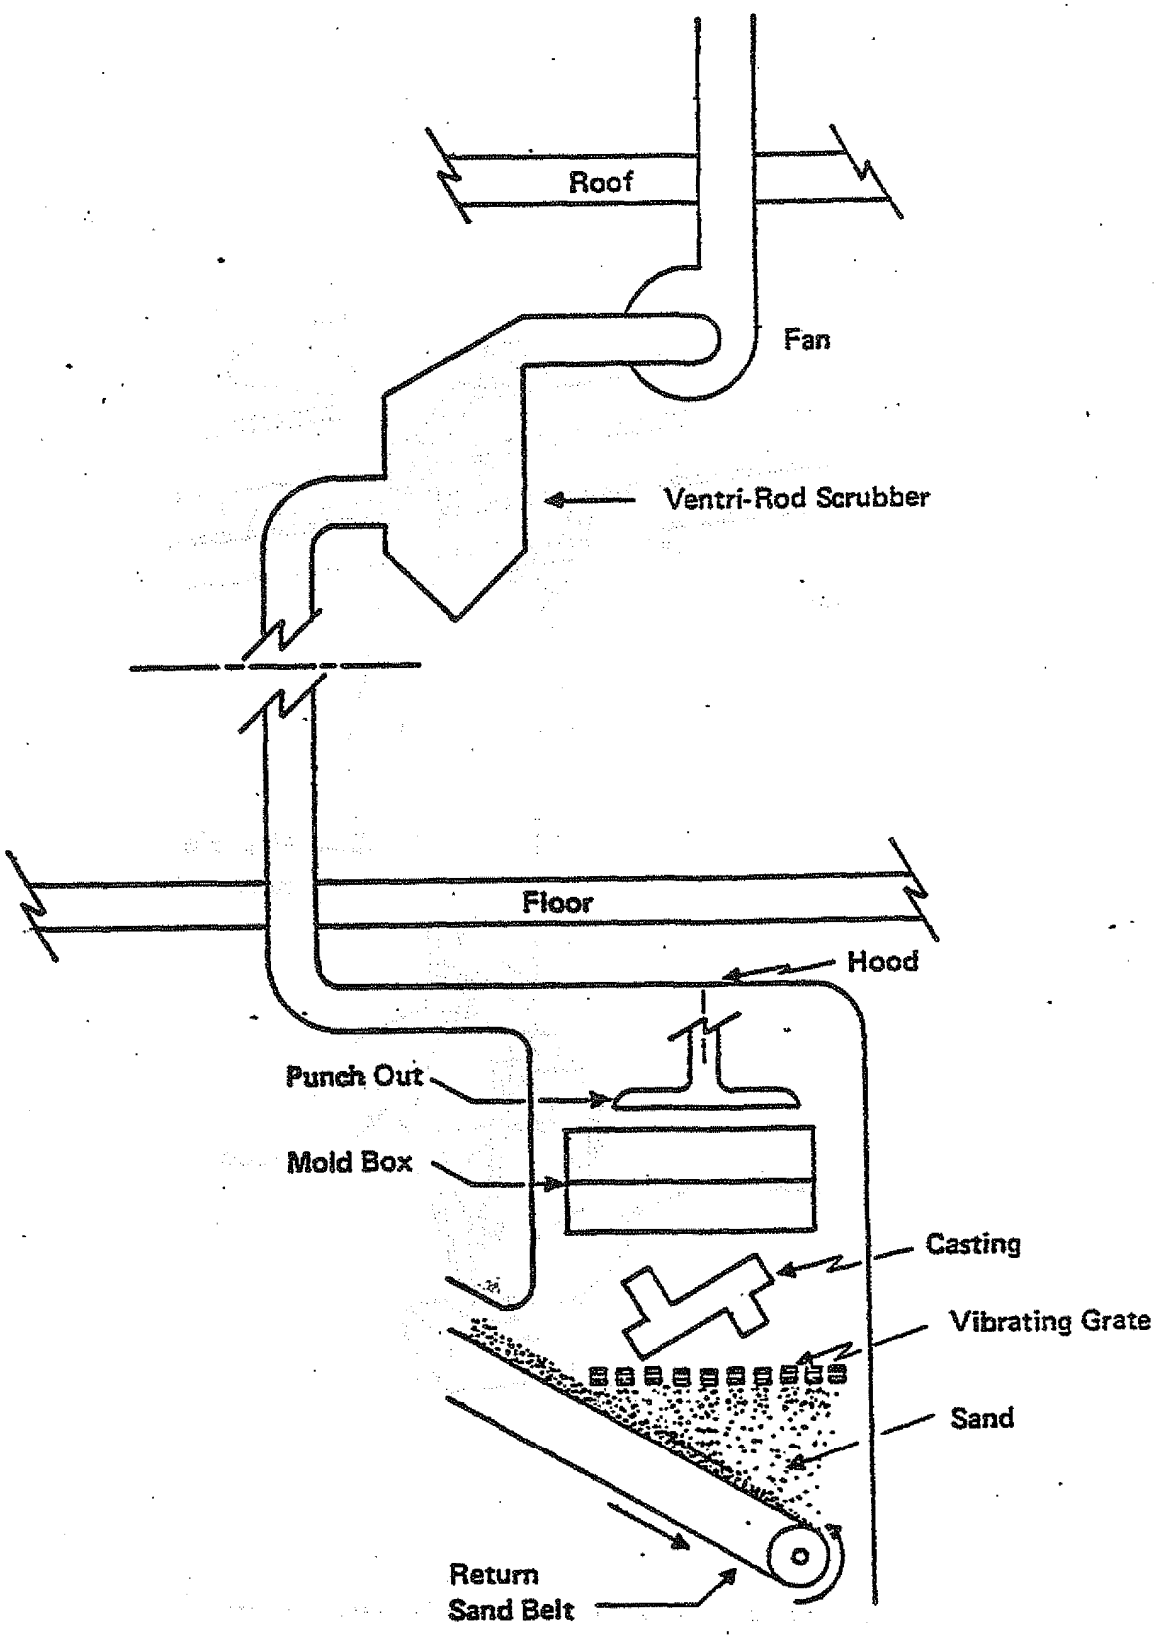

Figure 2.7-14. A casting shakeout control system.[43]

Particulate emissions from cleaning and finishing operations may be captured by local exhaust systems connected to either dry mechanical collectors (i.e., cyclones), fabric filters or wet collectors. Particulate emissions from abrasive shot blasting and tumble cleaners is commonly controlled by fabric filters or medium energy wet collectors. Dry mechanical collectors are also used at abrasive cleaning processes. Grinding operations are normally provided with local exhaust hoods connected to either high efficiency centrifugal collectors (multiple cyclones) or fabric filters.[44]

Coremaking effluents consist primarily of the gases emitted from the cold box, hot box, bake ovens and shell core machines and are usually exhausted to the atmosphere through a ventilation system or are passed through an odor scrubber before venting to the atmosphere.[44] Core ovens, when operated below 400°F and fired with natural gas, do not generally require air pollution control equipment and may be vented directly to the atmosphere. Emissions can be reduced by modifying the composition of the core binders and lowering the baking temperature.[45]

Medium energy wet collectors are best suited for moist sand preparation and handling. When dry sand conditions exist, fabric filters are occasionally used. Often some type of hood is used to capture emissions in sand conveyor systems especially at transfer points. As with many other processes, ductwork and exhaust fans are required in a complete collection system.[44] (Figure 2.7-15 illustrates the capture design on a typical sand-handling system.)

Table 2.7-8 summarizes the available control techniques, their effectiveness, estimated costs and RACM selections.

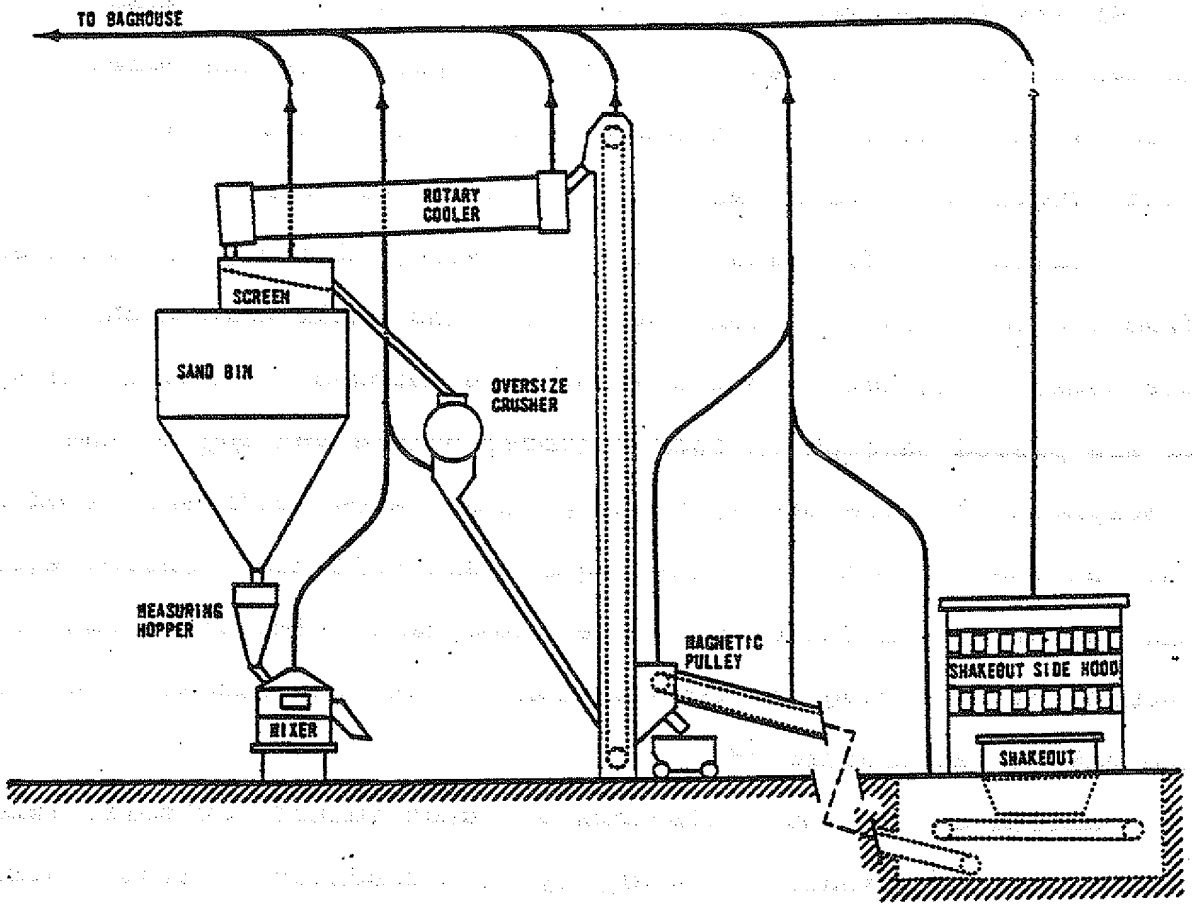

Figure 2.7-15. Capture design for a typical sand-handling system.[46]

2.7.2 Recommended Reasonably Available Control Measures (RACM)

The RACM selections for iron foundry fugitive sources are presented in Table 2.7-3.

The recommended control measure for cupola furnace charging emissions is the maintenance of sufficient draft through the charge door to effectively contain charging emissions and vent them to the existing primary control device. This is the most effective means of control that would not require a large capital outlay for cupolas having above-charge and below-charge take-offs. However, under this control measure, cupola furnace tapping emissions would be uncontrolled.

For control of electric arc and large electric induction furnaces which have primary controls, the selected RACM is maintenance of a continuous draft during the charging and tapping operations through the existing hooding for primary control. This technique could involve some modifications or extensions to the existing hoods to assure good capture. For furnaces which do not have primary controls, RACM consists of localized and canopy hooding which is vented to a fabric filter. For very small electric induction furnaces which have minimal visible emissions, no control is recommended.

No control is recommended for reverberatory furnaces since these are very low emitters of particulate matter and are not usually controlled.

The recommended RACM for ductile iron inoculation is hooding with exhaust to a fabric filter or wet scrubber. This system gives very good control and is commonly applied on existing foundries.

TABLE 2.7-8. A SUMMARY OF THE CONTROL ALTERNATIVES, EFFICIENCIES AND COSTS, AND THE RACM SELECTIONS FOR FUGITIVE DUST EMISSIONS FROM SOURCES AT IRON FOUNDRIES

Fugitive dust sources	Control alternatives	Control efficiency,%	Control costs, Jan. 1980, $		Cost benefit, $/lb	RACM selection
			Capital	Annualized		
(1) Cupola furnace charging and tapping	Hooding, vent to fabric filter	90[a]	336,000[a]	82,000[b]	2.60	Maintenance of continuous draft through charge door (if primary controls present); otherwise hooding, vent to fabric filter

[s] With alloying in the ladle.

The RACM selected for hot metal pouring operations is hooding and local exhaust to a wet scrubber. This type of system provides very good control (95%).

The selected RACM for control of the casting shakeout fugitive emissions is a system of hoods ducted to a common fabric filter or wet scrubber. This system would be designed to handle exhaust gases from the cleaning and cooling of castings, finishing operations, sand and binder mixing, core and mold makeup, and sand preparation and handling operations. This system is very effective and is used in existing foundries.

The sand unloading operations (truck or railcar dumping into receiving hopper) can be effectively controlled by use of wet suppression. Other options offer inferior control at costs on the same order of magnitude. For the pneumatic unloading and storage of sand, the general industry practice is the use of a fabric filter to control emissions from the storage hopper vent.

No control was selected for the core baking operation since with proper operation this is a relatively minor source of particulate emissions.

Assume furnace capacity = 11 tph or 33,000 tpy

(1) Cupola furnace charging and tapping
Emissions = (1.05 lb/ton)(33,000 tpy) = 35,000 lbs/yr

Hooding, vent to fabric filter

Capital cost = $336,000
Annual cost = 82,000

$$C/B = \frac{\$82,000/yr}{.9\ (35,000)} = \$2.60/lb$$

Building enclosure evacuation to fabric filter
No data

Maintenance of continuous draft through charge door

Capital cost = $150,000
Annual cost = 30,000

$$C/B = \frac{\$30,000/yr}{.70\ (35,000)} = \$1.22/lb$$

(2) Electric arc furnace charging and tapping
Emissions = (0.7 lb/ton)(33,000 tpy) = 23,100 lbs/yr (no alloying in ladle); (1.4 lbs/ton)(33,000 tpy) = 46,200 lbs/yr (with alloying in ladle)

Hooding, vent to fabric filter

Capital cost = $336,000
Annual cost = 82,000

$$C/B = \frac{\$82,000/yr}{.9\ (23,100)} = \$3.94/lb$$

$$C/B = \frac{\$82,000/yr}{.9\ (46,200)} = \$1.97/lb$$

Building enclosure, evacuation to fabric filter
No data

Maintenance of continuous draft during charging and tapping

Capital cost = $20,000
Annual cost = 4,000

$$C/B = \frac{\$4,000/yr}{.7\ (23,100)} = \$0.25/lb$$

$$C/B = \frac{\$4,000/yr}{.7\ (46,200)} = \$0.12/lb$$

(3) Electric induction furnace melting, charging and tapping
Emissions = (1.5 lb/ton)(33,000 tpy) = 50,000 lbs/yr

Hooding, vent to fabric filter

Capital cost = $336,000
Annual cost = 82,000

$$C/B = \frac{\$82,000/yr}{.9\ (50,000)} = \$1.82/lb$$

Building enclosure, evacuation to fabric filter
No data

Maintenance of continuous draft during charging and tapping

Capital cost = $20,000
Annual cost = 4,000

$$C/B = \frac{\$4,000/yr}{.7\ (50,000)} = \$0.11/lb$$

(4) Reverberatory furnace charging and tapping
Emissions = (0.1 lb/ton)(33,000 tpy) = 3,300 lbs/yr

Hooding, vent to fabric filter or ESP

Capital cost = $336,00
Annual cost = 82,000

$$C/B = \frac{\$82,000/yr}{.9\ (3,000)} = \$27.61$$

Building enclosure, evacuation to fabric or ESP
No data

(5) Ductile iron inoculation
Emissions = (3.9 lbs/ton)(33,000 tpy) = 129,000 lbs/yr

Hooding, vent to fabric filter or scrubber

Capital cost = $153,000
Annual cost = 33,000

$$C/B = \frac{\$33,000/yr}{0.9\ (129,000)} = \$0.28/lb$$

Room enclosure, vent to filter or scrubber
No data

(6) Pouring molten metal
Emissions = (2.115 lb/ton)(33,000 tpy) = 70,000 lbs/yr

Hoods, vent to wet scrubber

Capital cost = $63,000
Annual cost = 17,000

$$C/B = \frac{\$17,000/yr}{.95\ (70,000)} = \$0.26/lb$$

(7) Casting shakeout
Emissions = (7.0 lb/ton)(33,000) = 231,000 lbs/yr

Hoods, vent to wet scrubber or fabric filter

Capital cost = $234,000
Annual cost = 82,000

$$C/B = \frac{\$82,000/yr}{.95\ (231,000) + .9\ (16,000) + .95\ (330) + .9\ (148,500) + .9\ (1,000) + .9\ (43,000) + .9\ (1,300)}$$

$$= \$\ 0.20/lb$$

(8) Cooling and cleaning castings
Emissions = (0.48 lb/ton)(33,000 tpy) = 16,000 lbs/yr

Hooding, mechanical collector, fabric filter or scrubber

See (7)
C/B = $0.20/lb

(9) Finishing casting
Emissions = (0.01 lb/ton)(33,000 tpy) = 330 lbs/yr

Hooding, vent to mechanical collector, fabric filter or scrubber

See (7)
C/B = $0.20/lb

(10) Core and molding sand unloading and storage

Mechanical handling

Emissions = (.03 lb/ton)(33,000 tpy)(15)(.5) = 7,000 lbs/yr

Hooding, vent to mechanical collector

Capital cost = $33,600
Annual cost = 12,000

$$C/B = \frac{\$12,000/yr}{.8\ (7,000)} = \$2.14/lb$$

Wet suppression (chemical)

Capital cost = $26,000
Annual cost = 7,000

$$C/B = \frac{\$7,000/yr}{.85\ (7,000)} = \$1.18/lb$$

Enclosure

Capital cost = $15,000
Annual cost = 3,000

$$C/B = \frac{\$3,000/yr}{.5\ (7,000)} = \$0.85/lb$$

Pneumatic handling

Emissions = NA

Vent Storage hopper to fabric filter

No data

(11) Core sand and binder mixing

Emissions = (4.5 lb/ton)(33,000 tpy) = 148,500 lbs/yr

Hooding, vent to mechanical collector or fabric filter

See (7)

C/B = $0.20/lb

(12) Core making

Emissions = (0.35 lb/ton cores)(3,300 tpy) = ∿1,000 lbs/yr

Hooding, vent to fabric filter

See (7)

C/B = $0.20/lb

(13) Core baking
Emissions = (2.7 lb/ton core)(3,300 tpy) = 9,000 lbs/yr

Afterburners

Capital cost = $35,000
Annual cost = 21,000

$$C/B = \frac{\$21,000/yr}{.9\ (9,000)} = \$2.59/lb$$

(14) Mold sand preparation
Emissions = (1.3 lb/ton)(33,000 tpy) = 43,000 lbs/yr

Hooding, vent to fabric filter or scrubber

See (7)
C/B = $0.20/lb

(15) Mold makeup
Emissions = (0.04 lb/ton)(33,000 tpy) = 1,300 lbs/yr

Hooding, vent to fabric filter or scrubber

See (7)
C/B = $0.20/lb

		Inorganic HAP emissions		Organic HAP emissions	
Emission Unit	**Description**	**Inorganic HAP Emissions Present (Y/N)?**	**Remarks Regarding inorganic HAP emissions**	**Organic HAP Emissions Present (Y/N)?**	**Remarks Regarding organic HAP emissions**
EU01	Charge Handling	N	No inorganic HAP emissions expected due to the physical (solid) composition of the materials.	N	No organic HAP emissions identified in the chemical composition of the charge materials and no heat is applied at operation.
EU05	Refractory Burner #1	Y	Inorganic HAP emissions based on combustion of natural gas. See emission unit calculation sheet for quantification.	Y	Organic HAP emissions emitted based on combustion of natural gas. See emission unit calculation sheet for quantification.
EU06	Refractory Burner #2	Y	Inorganic HAP emissions based on combustion of natural gas. See emission unit calculation sheet for quantification.	Y	Organic HAP emissions emitted based on combustion of natural gas. See emission unit calculation sheet for quantification.
EU07	Induction Furnace #1	Y	Inorganic HAP emissions assumed based on metal chemistry, presence of metallic fumes and baghouse dust analytical. See air pollution control device calculations for quantification.	N	No organic HAP content identified in charge materials.
EU08	Induction Furnace #2	Y	Inorganic HAP emissions assumed based on metal chemistry, presence of metallic fumes and baghouse dust analytical. See air pollution control device calculations for quantification.	N	No organic HAP content identified in charge materials.
EU09	Induction Furnace #3	Y	Inorganic HAP emissions assumed based on metal chemistry, presence of metallic fumes and baghouse dust analytical. See air pollution control device calculations for quantification.	N	No organic HAP content identified in charge materials.
EU10	Induction Furnace #4	Y	Inorganic HAP emissions assumed based on metal chemistry, presence of metallic fumes and baghouse dust analytical. See air pollution control device calculations for quantification.	N	No organic HAP content identified in charge materials.
EU13	Hot Metal Transfer	Y	Inorganic HAP emissions assumed based on metal chemistry, presence of metallic fumes and baghouse dust analytical. See air pollution control device calculations for quantification.	N	No organic HAP content identified in charge materials.
EU15	Pouring Furnace #1	Y	Inorganic HAP emissions based on combustion of natural gas. See emission unit calculation sheet for quantification.	Y	Organic HAP emissions emitted based on combustion of natural gas. See emission unit calculation sheet for quantification.
EU16	Pouring Furnace #2	Y	Inorganic HAP emissions based on combustion of natural gas. See emission unit calculation sheet for quantification.	Y	Organic HAP emissions emitted based on combustion of natural gas. See emission unit calculation sheet for quantification.
EU17	Melt and Core/Mold Baghouse Waste Dust Silo	Y	Inorganic HAP emissions identified based on higher of CU01 and CU08 baghouse dust analyticals and presence of particulate emissions from several inorganic HAP emitting processes. See air pollution control device calculations for quantification.	N	No organic HAP emissions identified in the chemical composition of the charge materials and no heat is applied at operation.
EU18	Refractory Curing Mobile Burner	Y	Inorganic HAP emissions based on combustion of natural gas. See emission unit calculation sheet for quantification.	Y	Organic HAP emissions emitted based on combustion of natural gas. See emission unit calculation sheet for quantification.
EU19	Mold Silica Sand Silo	N	No inorganic HAP emissions expected due to the chemical composition of the incoming material (silica sand)	N	No organic HAP emissions expected due to the chemical composition of the incoming material (silica sand) and no heat is applied at the operation.
EU20	Blend Silo	N	No inorganic HAP emissions expected due to the chemical composition of the incoming material.	N	No organic HAP emissions expected due to physical composition of the incoming material and no heat is applied at the operation.
EU21	Bentonite Silo	N	No inorganic HAP emissions expected due to the chemical composition of the incoming material.	N	No organic HAP emissions expected due to physical composition of the incoming material and no heat is applied at the operation.
EU22	Mold Sand Handling and Preparation	Y	Limited inorganic HAP emissions emitted due to carryover metallics from pouring, cooling and shakeout prior to magnetic separation. Emissions based on baghouse dust analytical. See air pollution control device calculations for emission rates	N	No organic HAP emissions expected due to physical composition of the incoming material and no heat is applied at the operation.
EU33	Mold Making #1	N	No inorganic HAP emissions expected due to the chemical composition of the incoming material.	N	No organic HAP emissions expected due to physical composition of the incoming material and no heat is applied at the operation.
EU34	Mold Making #2	N	No inorganic HAP emissions expected due to the chemical composition of the incoming material.	N	No organic HAP emissions expected due to physical composition of the incoming material and no heat is applied at the operation.
EU35A	Core Silica Sand Silo A	N	No inorganic HAP emissions expected due to the chemical composition of the incoming material (silica sand)	N	No organic HAP emissions expected due to the chemical composition of the incoming material (silica sand) and no heat is applied at the operation.
EU35B	Core Silica Sand Silo B	N	No inorganic HAP emissions expected due to the chemical composition of the incoming material (silica sand)	N	No organic HAP emissions expected due to the chemical composition of the incoming material (silica sand) and no heat is applied at the operation.
EU36	Core Sand Handling and Preparation	N	No inorganic HAP emissions expected due to the chemical composition of the incoming material (silica sand)	N	No organic HAP emissions expected due to the chemical composition of the incoming material (silica sand) and no heat is applied at the operation.
EU39	PUCB Core Machine #1	N	No inorganic HAP emissions expected due to the chemical composition of the incoming material (silica sand, resin and catalyst)	Y	Organic HAP emissions emitted due to organic resin usage. See emission unit calculation worksheet.
EU40	PUCB Core Machine #2	N	No inorganic HAP emissions expected due to the chemical composition of the incoming material (silica sand, resin and catalyst)	Y	Organic HAP emissions emitted due to organic resin usage. See emission unit calculation worksheet.
EU41	PUCB Core Machine #3	N	No inorganic HAP emissions expected due to the chemical composition of the incoming material (silica sand, resin and catalyst)	Y	Organic HAP emissions emitted due to organic resin usage. See emission unit calculation worksheet.
EU42	PUCB Core Machine #4	N	No inorganic HAP emissions expected due to the chemical composition of the incoming material (silica sand, resin and catalyst)	Y	Organic HAP emissions emitted due to organic resin usage. See emission unit calculation worksheet.
EU43	Core Wash Station #1	N	No inorganic HAPs identified in chemical composition of core wash.	N	No organic HAPs identified in chemical composition of core wash.
EU44	Core Dryer #1	Y	Inorganic HAP emissions based on combustion of natural gas. See emission unit calculation sheet for quantification.	Y	organic HAP emissions emitted based on combustion of natural gas. See emission unit calculation sheet for quantification.
EU45	Core Dryer #2	Y	Inorganic HAP emissions based on combustion of natural gas. See emission unit calculation sheet for quantification.	Y	Organic HAP emissions emitted based on combustion of natural gas. See emission unit calculation sheet for quantification.

EU46	Core Dryer #3	Y	Inorganic HAP emissions based on combustion of natural gas. See emission unit calculation sheet for quantification.	Y	Organic HAP emissions emitted based on combustion of natural gas. See emission unit calculation sheet for quantification.
EU47	Core Dryer #4	Y	Inorganic HAP emissions based on combustion of natural gas. See emission unit calculation sheet for quantification.	Y	Organic HAP emissions emitted based on combustion of natural gas. See emission unit calculation sheet for quantification.
EU50	Pouring #1	Y	Inorganic HAP emissions assumed based on metal chemistry, presence of metallic fumes and baghouse dust analytical. See air pollution control device calculations for quantification.	Y	Organic HAP emissions based on thermal decomposition of mold and core sand organic material. See emission unit calculation worksheet.
EU51	Pouring #2	Y	Inorganic HAP emissions assumed based on metal chemistry, presence of metallic fumes and baghouse dust analytical. See air pollution control device calculations for quantification.	Y	Organic HAP emissions based on thermal decomposition of mold and core sand organic material. See combined pouring, cooling shakeout emission unit calculation worksheet for both "mold" and "core."
EU52	Mold Cooling	Y	Inorganic HAP emissions assumed based on metal chemistry, presence of metallic fumes and baghouse dust analytical. See air pollution control device calculations for quantification.	Y	Organic HAP emissions based on thermal decomposition of mold and core sand organic material. See combined pouring, cooling shakeout emission unit calculation worksheet for both "mold" and "core."
EU53	Shakeout Conveyor	Y	Inorganic HAP emissions assumed based on metal chemistry and baghouse dust analytical. See air pollution control device calculations for quantification.	Y	Organic HAP emissions based on thermal decomposition of mold and core sand organic material. See combined pouring, cooling shakeout emission unit calculation worksheet for both "mold" and "core."
EU57	Sand Plant Baghouse Waste Dust Silo	Y	inorganic HAP emissions assumed based on control device CU06 baghouse dust analytical and presence of captured particulate emissions from Shakeout Conveyor (EU53). See air pollution control device calculations for emission rates.	N	No organic HAP emissions expected due to physical composition of the incoming material and no heat is applied at the operation.
EU59	Casting Cooling	Y	Limited inorganic HAP emissions emitted due to carryover metal from pouring, cooling and shakeout. Emissions based on baghouse dust analytical. See air pollution control device calculations for emission rates	N	No organic HAP emissions expected due to physical composition of the incoming material and no heat is applied at the operation.
EU60	Sorting Conveyor	N	No inorganic HAP emissions expected given residual sand is the likely particulate.	N	No organic HAP emissions expected due to physical composition of the incoming material and no heat is applied at the operation.
EU61	Steel Shot Blasting #1	Y	Inorganic HAP emissions assumed based on metal chemistry and baghouse dust analytical. See air pollution control device calculations for quantification.	N	No organic HAPs identified in chemical composition of cast iron.
EU62	Steel Shot Blasting #2	Y	Inorganic HAP emissions assumed based on metal chemistry and baghouse dust analytical. See air pollution control device calculations for quantification.	N	No organic HAPs identified in chemical composition of cast iron.
EU63	Fettling Baghouse Waste Dust Silo	Y	inorganic HAP emissions assumed based on control device CU11 baghouse dust analytical and presence of captured particulate emissions from Shot Blasting and Griinding Operations. See air pollution control device calculations for emission rates.	N	No organic HAPs identified in chemical composition of cast iron.
EU64	Auto Grinding #1	Y	Inorganic HAP emissions assumed based on metal chemistry and baghouse dust analytical. See air pollution control device calculations for quantification.	N	No organic HAPs identified in chemical composition of cast iron.
EU65	Auto Grinding #2	Y	Inorganic HAP emissions assumed based on metal chemistry and baghouse dust analytical. See air pollution control device calculations for quantification.	N	No organic HAPs identified in chemical composition of cast iron.
EU66	Machining Lines (9)	Y	Inorganic HAP emissions assumed based on metal chemistry and baghouse dust analytical. See air pollution control device calculations for quantification.	N	No organic HAPs identified in chemical composition of cast iron.
EU67	Perforation Line #2	Y	Inorganic HAP emissions assumed based on metal chemistry and baghouse dust analytical. See air pollution control device calculations for quantification.	N	No organic HAPs identified in chemical composition of cast iron.
EU68	Paint Line #3	N	No inorganic HAP emissions expected due to chemical composition of the coatings.	Y	Organic HAP content based on chemical composition of the coating used. See emission unit calculation worksheet.
EU69	Paint Line #2	N	No inorganic HAP emissions expected due to chemical composition of the coatings.	Y	Organic HAP content based on chemical composition of the coating used. See emission unit calculation worksheet.
EU71	Paint Line #1	N	No inorganic HAP emissions expected due to chemical composition of the coatings.	Y	Organic HAP content based on chemical composition of the coating used. See emission unit calculation worksheet.
EU72	Emergency Generator #1	Y	Inorganic HAP emissions based on combustion of diesel fuel. See emission unit calculation sheet for quantification.	Y	Organic HAP emissions emitted based on combustion of diesel fuel. See emission unit calculation sheet for quantification.
EU73	Emergency Generator #2	Y	Inorganic HAP emissions based on combustion of diesel fuel. See emission unit calculation sheet for quantification.	Y	Organic HAP emissions emitted based on combustion of diesel fuel. See emission unit calculation sheet for quantification.
EU74	Emergency Generator #3	Y	Inorganic HAP emissions based on combustion of diesel fuel. See emission unit calculation sheet for quantification.	Y	Organic HAP emissions emitted based on combustion of diesel fuel. See emission unit calculation sheet for quantification.
EU75	Diesel Storage Tank	N	None quantified	N	None quantified
EU76	Paved Roads	N	No inorganic HAP emissions expected due to the operation	N	No organic HAP emissions expected due to the operation
EU77	Snag Grinder #1	Y	Inorganic HAP emissions assumed based on metal chemistry and baghouse dust analytical. See air pollution control device calculations for quantification.	N	No organic HAPs identified in chemical composition of cast iron.
EU78	Snag Grinder #2	Y	Inorganic HAP emissions assumed based on metal chemistry and baghouse dust analytical. See air pollution control device calculations for quantification.	N	No organic HAPs identified in chemical composition of cast iron.
EU79	Core Wash Station #2	N	No inorganic HAPs identified in chemical composition of core wash.	N	No organic HAPs identified in chemical composition of core wash.
EU80	Core Wash Station #3	N	No inorganic HAPs identified in chemical composition of core wash.	N	No organic HAPs identified in chemical composition of core wash.
EU81	Core Wash Station #4	N	No inorganic HAPs identified in chemical composition of core wash.	N	No organic HAPs identified in chemical composition of core wash.
EU82	Rust Preventative Application	N	No inorganic HAPs identified in chemical composition of core wash.	N	No organic HAPs identified in chemical composition of core wash.

SECTION A - PERMIT AUTHORIZATION

Pursuant to a duly submitted application the Kentucky Division for Air Quality (Division) hereby authorizes the operation of the equipment described herein in accordance with the terms and conditions of this permit. This permit has been issued under the provisions of Kentucky Revised Statutes (KRS) Chapter 224 and regulations promulgated pursuant thereto.

The permittee shall not construct, reconstruct, or modify any affected facilities without first submitting a complete application and receiving a permit for the planned activity from the permitting authority, except as provided in this permit or in 401 KAR 52:020, Title V Permits.

Issuance of this permit does not relieve the permittee from the responsibility of obtaining any other permits, licenses, or approvals required by the Kentucky Energy and Environment Cabinet (Cabinet) or any other federal, state, or local agency.

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS

Metal Melting Furnaces

Emission Group 01 – Melt Shop

Emission Unit 07 (EU07) **Induction Furnace #1**
Description:
Model: Junker – MFTGe Duomelt
Estimated Start of Construction: March 2017~~August 2016~~
Maximum Throughput: 10 tons gray iron/hr
Controls: Baghouse (CU01)

Emission Unit 08 (EU08) **Induction Furnace #2**
Description:
Model: Junker – MFTGe Duomelt
Estimated Start of Construction: March~~August~~ 2017~~6~~ Maximum Throughput: 10 tons gray iron/hr Controls: Baghouse (CU01)

Emission Unit 09 (EU09) **Induction Furnace #3**
Description:
Model: Junker – MFTGe Duomelt Estimated Start of Construction: July~~March~~ 2019
Maximum Throughput: 10 tons gray iron/hr
Controls: Baghouse (CU01)

Emission Unit 10 (EU10) **Induction Furnace #4**
Description:
Model: Junker – MFTGe Duomelt
Estimated Start of Construction: July~~March~~ 2019
Maximum Throughput: 10 tons gray iron/hr
Controls: Baghouse (CU01)

Description: Four (4) electric induction furnaces that have a maximum short-term capacity of 10 tons gray iron/hr each, or 40 tons/hr combined.

APPLICABLE REGULATIONS:
401 KAR 51:017, Prevention of significant deterioration of air quality.
401 KAR 59:010, New process operations.
401 KAR 63:002, Section 2(4)(bbbbb) implementing **40 CFR 63, Subpart ZZZZZ,** *National Emission Standards for Hazardous Air Pollutants for Iron and Steel Foundries Area Sources.*

1. **Operating Limitations:**
   a. The permittee shall comply with the pollution prevention management practices in 40 CFR 63.10885, the requirements in 40 CFR 63.10895(b) through (e), and the requirements in 40 CFR 63.10896 through 63.10900. [40 CFR 63.10895(a)]

Formatted: Right: 2.53"

Formatted: Right: 3.22"

Commented [CS4]: Need to integrate any new language of the revised Foundry Area Source Rule (Subpart ZZZZZ) issued post Residual Risk Technology Review (RTR).

As stated below, the preference would be to identify Subpart ZZZZZ at the facility level and let FWNA determine applicable requirements.

Commented [CS5]: The permit would be significant improved if Subpart ZZZZZ was identified as applicable but the specific requirements be left to FWNA to determine. While this is the langauge from Subpart ZZZZZ, 63.10897(a)(2) - (a)(4) is not applicable. Neither is (b)(3). Also 63.10898(a)(1), (a)(2), (a)(3), (a)(4), (a)(5) are not applicable.

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

b. The permittee shall operate a capture and collection system for each metal melting furnace. Each capture and collection system shall meet accepted engineering standards, such as those published by the American Conference of Governmental Industrial Hygienists. [40 CFR 63.10895(b)]

c. The permittee shall prepare and operate at all times according to a written operation and maintenance (O&M) plan for each control device for each induction furnace. The permittee shall maintain a copy of the O&M plan at the facility and make it available for review upon request. At a minimum, each plan shall contain the following information: [40 CFR 63.10896(a)]
   i. General facility and contact information; [40 CFR 63.10896(a)(1)]
   ii. Positions responsible for inspecting, maintaining, and repairing emissions control devices which are used to comply with 40 CFR 63, Subpart ZZZZZ; [40 CFR 63.10896(a)(2)]
   iii. Description of items, equipment, and conditions that will be inspected, including an inspection schedule for the items, equipment, and conditions. For baghouses that are equipped with bag leak detection systems, the O&M plan shall include the site- specific monitoring plan required in 40 CFR 63.10897(d)(2). [40 CFR 63.10896(a)(3)]
   iv. Identity and estimated quantity of the replacement parts that will be maintained in inventory; and [40 CFR 63.10896(a)(4)]
   v. Procedures for operating and maintaining a continuous parameter monitoring system (CPMS) in accordance with manufacturer's specifications. [40 CFR 63.10896(a)(5)]

d. The permittee may use any other O&M, preventative maintenance, or similar plan which addresses the requirements in 40 CFR 63.10896(a)(1) through (5) to demonstrate compliance with the requirements for an O&M plan. [40 CFR 63.10896(b)]

e. The permittee shall limit the operation of EU07, EU08, EU09, and EU10 to a combined maximum of 91,586 tons of gray iron processed per year, on a rolling 12-month basis. [401 KAR 51:017]

Compliance Demonstration Method:
Refer to **4. Specific Monitoring Requirements, 5. Specific Recordkeeping Requirements, 6. Specific Reporting Requirements,** and **7. Specific Control Equipment Operating Conditions.**

f. The permittee shall maintain the capture efficiency of each hood and exhaust pickup point serving EU07, EU08, EU09, and EU10 at or above 98% capture efficiency for PM, PM_{10}, and $PM_{2.5}$. [401 KAR 51:017]

~~g. The permittee shall ensure that the building removal efficiency for PM, PM_{10}, and $PM_{2.5}$ in the building that houses EU07, EU08, EU09, and EU10 is at least 90%. [401 KAR 51:017]~~

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

Compliance Demonstration Method:
Compliance with **1. Operating Limitations (f)** and **(g)** shall be demonstrated by completing the testing in **3. Testing Requirements (l),** submitting the report required in **6. Specific Reporting Requirements (c),** and monitoring according to **7. Specific Control Requirements (d).**

2. **Emission Limitations:**
   a. The permittee shall not discharge to the atmosphere emissions from any metal melting furnace or group of all metal melting furnaces that exceed 0.1 pounds of PM per ton of metal charged or 0.008 pounds of total metal HAP per ton of metal charged. [40 CFR 63.10895(c)(2)]

   b. The permittee shall not discharge to the atmosphere fugitive emissions from foundry operations that exhibit opacity greater than 20 percent (6-minute average), except for one 6-minute average per hour that does not exceed 30 percent. [40 CFR 63.10895(e); 401 KAR 51:017]
      i. For the purposes of 40 CFR 63, Subpart ZZZZZ and the limit above: *Fugitive emissions* means any pollutant released to the atmosphere that is not discharged through a system of equipment that is specifically designed to capture pollutants at the source, convey them through ductwork, and exhaust them using forced ventilation. *Fugitive emissions* include pollutants released to the atmosphere through windows, doors, vents, or other building openings. *Fugitive emissions* also include pollutants released to the atmosphere through other general building ventilation or exhaust systems not specifically designed to capture pollutants at the source. [40 CFR 63.10906]

Compliance Demonstration Method:
Refer to **3. Testing Requirements, 4. Specific Monitoring Requirements, 5. Specific Recordkeeping Requirements, 6. Specific Reporting Requirements,** and **7. Specific Control Equipment Operating Conditions.**

   c. The permittee shall not cause, suffer, allow, or permit any continuous (persisting more than 3 minutes) emission of particulate matter into the open air from a control device or stack associated with any affected facility which is equal to or greater than twenty (20) percent opacity, as measured by U.S. EPA Reference Method 9. [401 KAR 59:010, Section 3(1)(a); 401 KAR 51:017]

Compliance Demonstration Method:
Refer to **4. Monitoring Requirements(d)** for opacity compliance demonstration.

   d. For emissions from a control device or stack no person shall cause, suffer, allow or permit the emission into the open air of particulate matter from any affected facility which is in excess of the following: [401 KAR 59:010, Section 3(2)]
      i. For process weight rates of 0.50 ton/hr or less: 2.34 lb/hr
      ii. For process weight rates up to 30 tons/hr: $E_{PM_j} = 3.59P_j^{0.62}$

      Where:
      j = Emission Unit;

Commented [CS6]: Missing the alternative standard is another justification for just identifying Subpart ZZZZZ as applicable but not try and identify the specific portions of a rule but identify the rule as a facility-level requirement.

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

E'_{PM_j} = The allowable particulate emission rate for unit j in pounds/hour;
P_j = The average process weight rate in tons/hour

Compliance Demonstration Method:
Compliance with the hourly particulate emission limitations in 401 KAR 59:010, Section 3(2) is assumed when compliance with the limitations in **SECTION D(5)** is demonstrated.

e. Refer to **SECTION D** for group PSD limits for PM, PM_{10}, and $PM_{2.5}$, and source-wide HAP emission limitations.

3. **Testing Requirements:**

a. ~~The permittee shall conduct a performance test to demonstrate initial compliance with the applicable emissions limits for each metal melting furnace or group of all metal melting furnaces that is subject to an emissions limit in 40 CFR 63.10895(c) and for each building or structure housing foundry operations that is subject to the opacity limit for fugitive emissions in 40 CFR 63.10895(e). The permittee shall conduct the test within 180 days of startup and report the results in the notification of compliance status. [40 CFR 63.10898(a)~~]

Commented [CS7]: Emission unit has already demonstrated initial compliance with Subpart ZZZZZ

b. The permittee shall conduct subsequent performance tests to demonstrate compliance with all applicable PM or total metal HAP emissions limits in 40 CFR 63.10895(c) for a metal melting furnace or group of all metal melting furnaces no less frequently than every 5 years and each time the permittee elects to change an operating limit or make a process change likely to increase HAP emissions. [40 CFR 63.10898(b)]

c. The permittee shall conduct each performance test according to the requirements in 40 CFR 63.7(e)(1), Table 1 to 40 CFR 63, Subpart ZZZZZ, and 40 CFR 63.10898(d) through (g). [40 CFR 63.10898(c)]

d. To determine compliance with the applicable PM or total metal HAP emissions limit in 40 CFR 63.10895(c) for a metal melting furnace in a lb/ton of metal charged format, compute the process-weighted mass emissions (E_p) for each test run using Equation 1: [40 CFR 63.10898(d)]

$$E_p = \frac{C \times Q \times T}{P \times K}$$

(Equation 1)

Where:

E_p = Process-weighted mass emissions rate of PM or total metal HAP, pounds of PM or total metal HAP per ton (lb/ton) of metal charged;
C = Concentration of PM or total metal HAP measured during performance test run, grains per dry standard cubic foot (gr/dscf);
Q = Volumetric flow rate of exhaust gas, dry standard cubic feet per hour (dscf/hr);
T = Total time during a test run that a sample is withdrawn from the stack during melt production cycle, hr;
P = Total amount of metal charged during the test run, tons; and

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

K = Conversion factor, 7,000 grains per pound.

e. To determine compliance with an emissions limit for situations when multiple sources are controlled by a single control device, but only one source operates at a time or other situations that are not expressly considered in 40 CFR 63.10898(d) through (f), the permittee shall submit a site-specific test plan to the Division for approval according to the requirements in 40 CFR 63.7(c)(2) and (3). [40 CFR 63.10898(g)]

f. The permittee shall conduct each opacity test for fugitive emissions according to the requirements in 40 CFR 63.6(h)(5) and Table 1 to 40 CFR 63, Subpart ZZZZZ. [40 CFR 63.10898(h)]

g. The permittee shall conduct subsequent performance tests to demonstrate compliance with the opacity limit in 40 CFR 63.10895(e) no less frequently than every 6 months and each time a process change likely to increase fugitive emissions in made. [40 CFR 63.10898(i)]

h. In the performance test report, the permittee shall certify that the capture system operated normally during the performance test. [40 CFR 63.10898(j)]

i. For each metal melting furnace subject to a PM limit in 40 CFR 63.10895(c), the permittee shall: [40 CFR 63, Subpart ZZZZZ, Table 1(1)]
   i. Select sampling port locations and the number of traverse points in each stack or duct using EPA Method 1 or 1A (40 CFR part 60, appendix A). Sampling sites must be located at the outlet of the control device (or at the outlet of the emissions source if no control device is present) prior to any releases to the atmosphere. [40 CFR 63, Subpart ZZZZZ, Table 1(1)(a)]
   ii. Determine volumetric flow rate of the stack gas using Method 2, 2A, 2C, 2D, 2F, or 2G (40 CFR part 60, appendix A). [40 CFR 63, Subpart ZZZZZ, Table 1(1)(b)]
   iii. Determine dry molecular weight of the stack gas using EPA Method 3, 3A, or 3B (40 CFR part 60, appendix A). The permittee may also use as an alternative to EPA Method 3B (40 CFR part 60, appendix A), the manual method for measuring the oxygen, carbon dioxide, and carbon monoxide content of exhaust gas, ANSI/ASME PTC 19.10-1981, "Flue and Exhaust Gas Analyses" (incorporated by reference—see 40 CFR 63.14). [40 CFR 63, Subpart ZZZZZ, Table 1(1)(c)]
   iv. Measure moisture content of the stack gas using EPA Method 4 (40 CFR part 60, A). [40 CFR 63, Subpart ZZZZZ, Table 1(1)(d)]
   v. Determine PM concentration using EPA Method 5, 5B, 5D, 5F, or 5I, as applicable (40 CFR part 60, appendix A). [40 CFR 63, Subpart ZZZZZ, Table 1(1)(e)]
      1) Collect a minimum sample volume of 60 dscf of gas during each PM sampling run. The PM concentration is determined using only the front-half (probe rinse and filter) of the PM catch. [40 CFR 63, Subpart ZZZZZ, Table 1(1)(i)]
   vi. A minimum of three valid test runs are needed to comprise a PM performance test. [40 CFR 63, Subpart ZZZZZ, Table 1(1)(iii)]
   vii. Sample PM only during normal melt production conditions, which may include, but are not limited to the following operations: Charging, melting, alloying, refining, slagging, and tapping. [40 CFR 63, Subpart ZZZZZ, Table 1(1)(v)]

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

viii. Determine and record the total combined weight of tons of metal charged during the duration of each test run. The permittee shall compute the process-weighted mass emissions of PM according to Equation 1 of 40 CFR 63.10898(d) for an individual furnace. [40 CFR 63, Subpart ZZZZZ, Table 1(1)(vi)]

j. For fugitive emissions from buildings or structures housing any iron and steel foundry emissions sources subject to opacity limit in 40 CFR 63.10895(e), the permittee shall: [40 CFR 63, Subpart ZZZZZ, Table 1(2)]
   i. Using a certified observer, conduct each opacity test according to EPA Method 9 (40 CFR part 60, appendix A-4) and 40 CFR 63.6(h)(5). [40 CFR 63, Subpart ZZZZZ, Table 1(2)(a)]
      1) The certified observer may identify a limited number of openings or vents that appear to have the highest opacities and perform opacity observations on the identified openings or vents in lieu of performing observations for each opening or vent from the building or structure. Alternatively, a single opacity observation for the entire building or structure may be performed, if the fugitive release points afford such an observation. [40 CFR 63, Subpart ZZZZZ, Table 1(2)(a)(i)]
      2) During testing intervals when PM performance tests are being conducted, conduct the opacity test such that the opacity observations are recorded during the PM performance tests. [40 CFR 63, Subpart ZZZZZ, Table 1(2)(a)(ii)]
   ii. As alternative to Method 9 performance test, conduct visible emissions test by Method 22 (40 CFR part 60, appendix A-7). The test is successful if no visible emissions are observed for 90 percent of the readings over 1 hour. If VE is observed greater than 10 percent of the time over 1 hour, then the facility must conduct another performance test as soon as possible, but no later than 15 calendar days after the Method 22 test, using Method 9 (40 CFR part 60, appendix A-4). [40 CFR 63, Subpart ZZZZZ, Table 1(2)(b)]
      1) The observer may identify a limited number of openings or vents that appear to have the highest visible emissions and perform observations on the identified openings or vents in lieu of performing observations for each opening or vent from the building or structure. Alternatively, a single observation for the entire building or structure may be performed, if the fugitive release points afford such an observation. [40 CFR 63, Subpart ZZZZZ, Table 1(2)(b)(i)]
      2) During testing intervals when PM performance tests are being conducted, conduct the visible emissions test such that the observations are recorded during the PM performance tests. [40 CFR 63, Subpart ZZZZZ, Table 1(2)(b)(ii)]

k. Except as provided in 401 KAR 50:045, performance tests used to demonstrate compliance with 401 KAR 59:010, Section 3 shall be conducted according to the following methods. Kentucky Methods 50 and 150(F-1) and other methods are filed by reference in 401 KAR 50:015. [401 KAR 59:010, Section 4]
   i. Reference Method 5 for the emission rates of particulate matter and the associated moisture content. [401 KAR 59:010, Section 4(1)]
   ii. Reference Method 1 for sample and velocity traverses. [401 KAR 59:010, Section 4(2)]

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

iii. Reference Method 2 for velocity and volumetric flow rate. [401 KAR 59:010, Section 4(3)]
iv. Reference Method 3 for gas analysis. [401 KAR 59:010, Section 4(4)]
v. Reference Method 9 for opacity of continuous emissions. [401 KAR 59:010, Section 4(5)]
vi. For Reference Method 5, Reference Method 1 shall be used to select the sampling site and the number of traverse sampling points. The sampling time for each run shall be at least sixty (60) minutes and the minimum sample volume shall be 0.85 dscm (thirty (30) dscf) except that smaller sampling time or volumes, when necessitated by process variables or other factors, may be approved by the Cabinet. [401 KAR 59:010, Section 4(7)]

l. The permittee shall, within 180 days of permit issuance~~after startup of EU07, EU08, EU09, and EU10,~~ verify the direction of airflow through both the largest building wall opening closest to the process and the largest opening of each hood and exhaust pickup point, is inward using a smoke tube and the following procedures: [401 KAR 51:017]
   i. The direction of airflow shall be monitored for at least 1 hour, with checks made no more than 10 minutes apart.
   ii. The ~~fan RPM and~~ volumetric flow rate shall be monitored during the test.

m. Pursuant to 401 KAR 59:005, Section 2(2) and 401 KAR 50:045, Section 1, performance testing using the Reference Methods specified in 401 KAR 50:015 shall be conducted as required by the Division.

n. Refer to **SECTION D** for group testing requirements.

4. Specific Monitoring Requirements:

a. The permittee shall make monthly inspections of the equipment that is important to the performance of the total capture system (i.e., pressure sensors, dampers, and damper switches). This inspection shall include observations of the physical appearance of the equipment (e.g., presence of holes in the ductwork or hoods, flow constrictions caused by dents or accumulated dust in the ductwork, and fan erosion). The permittee shall repair any defect or deficiency in the capture system as soon as practicable, but no later than 90 days. The permittee shall record the date and results of each inspection and the date of repair of any defect or deficiency. [40 CFR 63.10897(e)]

~~b. The permittee shall install, operate, and maintain each CPMS or other measurement device according to the O&M plan. The permittee shall record all information needed to document conformance with these requirements. [40 CFR 63.10897(f)]~~

Commented [CS8]: There is no CPMS or other measurement device requirements by the rule.

~~c.~~b. In the event of an exceedance of an established emissions limitation (including an operating limit), the permittee shall restore operation of the emissions source (including the control device and associated capture system) to its normal or usual manner or operation as expeditiously as practicable in accordance with good air pollution control practices for minimizing emissions. The response shall include minimizing the period of any startup, shutdown or malfunction and taking any necessary corrective actions to

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

restore normal operation and prevent the likely recurrence of the exceedance. The permittee shall record the date and time correction action was initiated, the correction action taken, and the date corrective action was completed. [40 CFR 63.10897(g)]

~~d. The permittee shall perform a qualitative visual observation of the opacity of emissions at each stack daily and maintain a log of the observations. If visible emissions from a stack are seen (not including condensed water in the plume), then an inspection of process/control equipment shall be initiated and corrective action taken. If visible emissions are present after the corrective action, the process(s) shall be shut down and shall not operate again until repairs have been made that result in no visible emissions from the process(s) during operation. In lieu of shutting the process(s) down, the permittee may determine the opacity using Reference Method 9. If the opacity limit is not exceeded, the process(s) may continue to operate. [401 KAR 51:017]~~

Commented [CS9]: There are no fugitive egress point stacks and the baghouse has a BLDS installed, therefore a daily qualitative visual observation should not be required.

~~e.~~c. For each emission unit listed above, the permittee shall monitor the following parameters:

i. Monthly and 12-month rolling total hours of operation;
ii. Monthly and 12-month rolling total throughput;

~~f.~~d. Refer to **SECTION E**.

5. Specific Recordkeeping Requirements:

a. In addition to the records required by 40 CFR 63.10(b)(2)(iii) and (vi) through (xiv) and (b)(3), the permittee shall keep records of the information specified in 40 CFR 63.10899(b)(1) through (13). [40 CFR 63.10899(b)]

Commented [CS10]: Below is incomplete list of requirements identified by 40 CFR 63.10899(b). It would improve the permit as stated by removing all Subpart ZZZZZ related language and have the requirements be global in nature. Otherwise all applicable requirements should be identified.

i. The permittee shall keep records of monthly metal melt production for each calendar year. [40 CFR 63.10899(b)(6)]
ii. The permittee shall keep a copy of the operation and maintenance plan as required by 40 CFR 63.10896(a) and records that demonstrate compliance with plan requirements. [40 CFR 63.10899(b)(7)]
iii. If emissions averaging is used, the permittee shall keep records of the monthly metal melting rate for each furnace at the iron and steel foundry, and records of the calculated pounds of PM or total metal HAP per ton of metal melted for the group of all metal melting furnaces required by 40 CFR 63.10897(h). [40 CFR 63.10899(b)(8)]
iv. The permittee shall keep records for bag leak detection systems as follows: [40 CFR 63.10899(b)(9)]
    1) Records of the bag leak detection system output; [40 CFR 63.10899(b)(9)(i)]
    2) Records of bag leak detection system adjustments, including the date and time of the adjustment, the initial bag leak detection system settings, and the final bag leak detection system settings; and [40 CFR 63.10899(b)(9)(ii)]
    3) The date and time of all bag leak detection system alarms, and for each valid alarm, the time corrective action was initiated, the corrective action taken, and the date on which corrective action was completed. [40 CFR 63.10899(b)(9)(iii)]
v. The permittee shall keep records of capture system inspections and repairs as required by 40 CFR 63.10897(e). [40 CFR 63.10899(b)(10)]
vi. The permittee shall keep records demonstrating conformance with the specifications for the operation of CPMS as required by 40 CFR 63.10897(f). [40 CFR 63.10899(b)(11)]

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

vii. The permittee shall keep records of corrective action(s) for exceedances and excursions as required by 40 CFR 63.10897(g). [40 CFR 63.10899(b)(12)]

viii. The permittee shall record the results of each inspection and maintenance required by 40 CFR 63.10897(a) for PM control devices in a logbook (written or electronic format). The permittee shall keep the logbook onsite and make the logbook available to the Division upon request. The permittee shall keep records of the information specified in 40 CFR 63.10899(b)(13)(i) through (iii). [40 CFR 63.10899(b)(13)]

1) The date and time of each recorded action for a fabric filter, the results of each inspection, and the results of any maintenance performed on the bag filters. [40 CFR 63.10899(b)(13)(i)]

~~b.~~ The permittee shall record the occurrence, duration, cause and any corrective action taken for any incident or malfunction that occurs that causes or might cause an exceedance of the particulate emission or opacity standard when an emission unit is in operation. ~~A log of Method 9 observations and qualitative visual observations shall be kept and made available for inspection.~~

Commented [CS11]: Baghouse has a BLDS and semiannual opacity standard. An additional log is unnecessary.

Formatted: Normal, Indent: Left: 0.74", Right: 0.48", Space Before: 0.05 pt, Tab stops: 0.99", Left

~~c.~~b. For each emission unit listed above, the permittee shall maintain records of the following:

i. Monthly and 12-month rolling total hours of operation;
ii. Monthly and 12-month rolling total throughput;
iii. SDSs for all materials used.

~~d.~~c. The permittee shall maintain records of the calculations required in **SECTION D**.

6. Specific Reporting Requirements:

a. The permittee shall submit semiannual compliance reports to the Division according to the requirements in 40 CFR 63.10(e). The reports shall include, at a minimum, the following information as applicable: [40 CFR 63.10899(c)]

i. Summary information on the number, duration, and cause (including unknown cause, if applicable) of excursions or exceedances, as applicable, and the corrective action taken; [40 CFR 63.10899(c)(1)]

ii. Summary information on the number, duration, and cause (including unknown cause, if applicable) for monitor downtime incidents (other than downtime associated with zero and span or other calibration checks, if applicable); and [40 CFR 63.10899(c)(2)]

iii. Summary information on any deviation from the pollution prevention management practices in 40 CFR 63.10885 and 63.10886 and the operation and maintenance requirements 40 CFR 63.10896 and the corrective action taken. [40 CFR 63.10899(c)(3)]

Commented [CS12]: This language should either be removed if addressing Subpart ZZZZZ at the facility level or changed to reflect the revised Subpart ZZZZZ RTR requirements.

~~b. The notification of compliance status required by 40 CFR 63.9(h) shall include this certification of compliance, signed by a responsible official: [40 CFR 63, Subpart ZZZZZ, Table 4]~~

~~i. "This facility operates a capture and collection system for each emissions source subject to this subpart according to 40 CFR 63.10895(b)."~~

Commented [CS13]: Notification of Compliance Status has been submitted.

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

~~ii. "This facility complies with the PM emissions limit in 40 CFR 63.10895(e) for each metal melting furnace based on a previous performance test in accordance with 40 CFR 63.10898(a)(1)."~~

~~iii. "This facility has prepared and will operate by an operation and maintenance plan according to 40 CFR 63.10896(a)."~~

~~iv. "This facility has prepared and will operate by a site-specific monitoring plan for each bag leak detection system and submitted the plan to the Division for approval according to 40 CFR 63.10897(d)(2)."~~

~~c. The permittee shall, within 90 days after conducting the initial performance test, submit the design information and analysis, with supporting documentation, demonstrating that each capture and collection system (hood, canopy, open entrance, etc.) meets accepted engineering standards, such as those published by the American Conference of Governmental Industrial Hygienists, and is capable of meeting the capture effieiency requirement in **1. Operating Limitations (f).** [401 KAR 51:017]~~

7. Specific Control Equipment Operating Conditions:

a. For all emission units listed above, the permittee shall install, calibrate, maintain and operate, according to manufacturer's specifications, fabric filters designed to achieve the BACT limits in **SECTION D(5)**. The permittee shall make these records of the manufacturer's specification for the fabric filters available for inspection by the Division. [401 KAR 51:017]

b. Refer to **SECTION E** for control device requirements pursuant to 40 CFR 63, Subpart ZZZZZ and 401 KAR 51:017.

c. The permittee shall operate the control devices associated with each emission unit at all times that the emission unit is operating. [401 KAR 51:017]

d. For the baghouse associated with EU07, EU08, EU09, and EU10, the permittee shall continuously monitor the inlet volumetric flow rate in the stack, and maintain it at 80% or above the level measured during the testing required by **3. Testing Requirements (l)**.

e. The permittee shall install, calibrate, maintain and operate, according to manufacturer's specifications (as applicable), a monitoring device (differential pressure gauges or manometers) to determine the pressure drop across each baghouse, at a minimum, once a day~~shift~~ during the operation of the unit. A permanent label displaying the operating range established for each baghouse shall be posted next to the selected instrument. [401 KAR 51:017]

Commented [CS14]: Comment made because certain pressure monitoring devices cannot be calibrated.

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

Foundry Operations

Emission Unit	Description	BACT Control Device	Maximum Hourly Capacity	PSD Operating Limitations	Maximum Burner Capacity	Estimated Start of Construction
Emission Group 01 – Melt Shop						
EU01	Scrap Steel Storage	None	25.3 ton gray iron/hr, each	91,586 ton gray iron/yr	N/A	August 2016
EU02	Alloy Storage	Baghouse (CU01)		91,586 ton gray iron/yr	N/A	August 2016
EU03	Scrap Drying	None		60.12 MMscf/yr	7 MMBtu/hr	August 2016
EU04	Scrap Cleaning	Baghouse (CU01)		91,586 ton gray iron/yr & 120.24 MMscf/yr	14 MMBtu/hr	August 2016
EU05	Refractory Burner #1	None	N/A	73 MMscf/yr	8.50 MMBtu/hr	August 2016
EU06	Refractory Burner #2	None	N/A	73 MMscf/yr	8.50 MMBtu/hr	March 2019
EU11	Holding Furnace #1	Baghouse (CU01)	12.7 ton gray iron/hr, each	45,793 ton gray iron/yr & 24.99 MMscf/yr	2.91 MMBtu/hr	August 2016
EU12	Holding Furnace #2			45,793 ton gray iron/yr & 24.99 MMscf/yr	2.91 MMBtu/hr	March 2019
EU13	Transport Ladle #1	None		45,793 ton gray iron/yr	N/A	August 2016
EU14	Transport Ladle #2	None		45,793 ton gray iron/yr	N/A	March 2019
EU15	Pouring Furnace #1	Baghouse (CU01)		45,793 ton gray iron/yr & 24.99 MMscf/yr	2.91 MMBtu/hr	August 2016

~~*Note: The CU08 Baghouse will not be constructed until Phase 2 of construction. During Phase 1, all processes that would have been ducted to CU08 will be ducted to CU01. Refer to **Section H** for more details.~~

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

Description: The processes listed above are considered to meet the definition of Foundry Operations, as defined in 40 CFR 63.10906, which means all process equipment and practices used to produce metal castings for shipment, including: Mold or core making and coating; scrap handling and preheating; metal melting and inoculation; pouring, cooling, and shakeout; shotblasting, grinding, and other metal finishing operations; and sand handling.

APPLICABLE REGULATIONS:
401 KAR 51:017, Prevention of significant deterioration of air quality.
401 KAR 59:010, New process operations.
401 KAR 63:002, Section 2(4)(bbbbb) implementing **40 CFR 63, Subpart ZZZZZ,** *National Emission Standards for Hazardous Air Pollutants for Iron and Steel Foundries Area Sources.*

1. **Operating Limitations:**
   a. For each segregated metallic scrap storage area, bin or pile, the permittee shall comply with the materials acquisition requirements in 40 CFR 63.10885(a)(1) or (2). The permittee shall keep a copy of the material specifications onsite and readily available to all personnel with material acquisition duties, and provide a copy to each of the scrap providers. The permittee may have certain scrap subject to 40 CFR 63.10885(a)(1) and other scrap subject to 40 CFR 63.10885(a)(2) at the facility provided the metallic scrap remains segregated until charge make-up. [40 CFR 63.10885(a)]
      i. The permittee shall prepare and operate at all times according to written material specifications for the purchase and use of only metal ingots, pig iron, slitter, or other materials that do not include post-consumer automotive body scrap, post-consumer engine blocks, post-consumer oil filters, oily turnings, lead components, chlorinated plastics, or free liquids. For the purpose of 40 CFR 63, Subpart ZZZZZ, "free liquids" is defined as material that fails the paint filter test by EPA Method 9095B, "Paint Filter Liquids Test" (revision 2), November 2004 (incorporated by reference—see 40 CFR 63.14). The requirements for no free liquids do not apply if the permittee can demonstrate that the free liquid is water that resulted from scrap exposure to rain. [40 CFR 63.10885(a)(1)]
      ii. The permittee shall prepare and operate at all times according to written material specifications for the purchase and use of only iron and steel scrap that has been depleted (to the extent practicable) of organics and HAP metals in the charge materials used by the iron and steel foundry. The materials specifications shall include at minimum the information specified in 40 CFR 63.10885(a)(2)(i). [40 CFR 63.10885(a)(2)]
         1) Specifications for metallic scrap materials charged to a scrap preheater or metal melting furnace to be depleted (to the extent practicable) of the presence of used oil filters, chlorinated plastic parts, accessible lead-containing components (such as batteries and wheel weights), and a program to ensure the scrap materials are drained of free liquids. [40 CFR 63.10885(a)(2)(i)]

   b. For scrap containing motor vehicle scrap, the permittee shall procure the scrap pursuant to one of the compliance options in 40 CFR 63.10885(b)(1), (2), or (3) for each scrap provider, contract, or shipment. For scrap that does not contain motor vehicle scrap, the permittee shall procure the scrap pursuant to the requirements in 40 CFR 63.10885(b)(4)

Commented [CS17]: To clarify these requirements are for Charge Handling or Melting. The Charge Handling emission unit should be its own Grouping or grouped with the furnaces. These requirements should be relocated to either the facility-level or to the Melting Group as they are confusing where they are.

Commented [CS18]: See above comment.

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

for each scrap provider, contract, or shipment. The permittee may have one scrap provider, contract, or shipment subject to one compliance provision and others subject to another compliance provision. [40 CFR 63.10885(b)]

i. Site-specific plan for mercury switches. The permittee shall comply with the requirements in 40 CFR 63.10885(b)(1)(i) through (v). [40 CFR 63.10885(b)(1)]
   1) The permittee shall include a requirement in the scrap specifications for removal of mercury switches from vehicle bodies used to make the scrap. [40 CFR 63.10885(b)(1)(i)]
   2) The permittee shall prepare and operate according to a plan demonstrating how the facility will implement the scrap specification in 40 CFR 63.10885(b)(1)(i) for removal of mercury switches. The permittee shall submit the plan to the Division for approval. The permittee shall operate according to the plan as submitted during the review and approval process, operate according to the approved plan at all times after approval, and address any deficiency identified by the Division within 60 days following disapproval of a plan. The permittee may request approval to revise the plan and may operate according to the revised plan unless and until the revision is disapproved by the Division. The Division may change the approval status of the plan upon 90-days written notice based upon the semiannual report or other information. The plan shall include: [40 CFR 63.10885(b)(1)(ii)]
      A. A means of communicating to scrap purchasers and scrap providers the need to obtain or provide motor vehicle scrap from which mercury switches have been removed and the need to ensure the proper management of the mercury switches removed from the scrap as required under the rules implementing subtitle C of the Resource Conservation and Recovery Act (RCRA) (40 CFR parts 261 through 265 and 268). The plan shall include documentation of direction to appropriate staff to communicate to suppliers throughout the scrap supply chain the need to promote the removal of mercury switches from end- of-life vehicles. Upon the request of the Division, the permittee shall provide examples of materials that are used for outreach to suppliers, such as letters, contract language, policies for purchasing agents, and scrap inspection protocols; [40 CFR 63.10885(b)(1)(ii)(A)]
      B. Provisions for obtaining assurance from scrap providers motor vehicle scrap provided to the facility meet the scrap specification; [40 CFR 63.10885(b)(1)(ii)(B)]
      C. Provisions for periodic inspections or other means of corroboration to ensure that scrap providers and dismantlers are implementing appropriate steps to minimize the presence of mercury switches in motor vehicle scrap and that the mercury switches removed are being properly managed, including the minimum frequency such means of corroboration will be implemented; and [40 CFR 63.10885(b)(1)(ii)(C)]
      D. Provisions for taking corrective actions (i.e., actions resulting in scrap providers removing a higher percentage of mercury switches or other mercury-containing components) if needed, based on the results of procedures implemented in 40 CFR 63.10885(b)(1)(ii)(C). [40 CFR 63.10885(b)(1)(ii)(D)]

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

3) The permittee shall require each motor vehicle scrap provider to provide an estimate of the number of mercury switches removed from motor vehicle scrap sent to the facility during the previous year and the basis for the estimate. The Division may request documentation or additional information at any time. [40 CFR 63.10885(b)(1)(iii)]
4) The permittee shall establish a goal for each scrap supplier to remove at least 80 percent of the mercury switches. Although a site-specific plan approved under 40 CFR 63.10885(b)(1) may require only the removal of convenience light switch mechanisms, the Division will credit all documented and verifiable mercury-containing components removed from motor vehicle scrap (such as sensors in anti-locking brake systems, security systems, active ride control, and other applications) when evaluating progress towards the 80 percent goal. [40 CFR 63.10885(b)(1)(iv)]
5) For each scrap provider, the permittee shall submit semiannual progress reports to the Division that provide the number of mercury switches removed or the weight of mercury recovered from the switches, the estimated number of vehicles processed, an estimate of the percent of mercury switches removed, and certification that the removed mercury switches were recycled at RCRA- permitted facilities or otherwise properly managed pursuant to RCRA subtitle C regulations referenced in 40 CFR 63.10885(b)(1)(ii)(A). This information can be submitted in aggregate form and does not have to be submitted for each shipment. The Division may change the approval status of a site-specific plan following 90- day's notice based on the progress reports or other information. [40 CFR 63.10885(b)(1)(v)]

~~ii. The permittee shall certify in the notification of compliance status that the permittee participates in and purchases motor vehicle scrap only from scrap providers who participate in a program for removal of mercury switches that has been approved by the U.S. EPA based on the criteria in 40 CFR 63.10885(b)(2)(i) through (iii). If the permittee purchases motor vehicle scrap from a broker, the permittee shall certify that all scrap received from that broker was obtained from other scrap providers who participate in a program for the removal of mercury switches that has been approved by the U.S. EPA based on the criteria in 40 CFR 63.10885(b)(2)(i) through (iii). The National Mercury Switch Recovery Program and the State of Maine Mercury Switch Removal Program are EPA-approved programs under 40 CFR 63.10885(b)(2) unless and until the U.S. EPA disapproves the program (in part or in whole) under 40 CFR 63.10885(b)(2)(iii). [40 CFR 63.10885(b)(2)]~~

~~1) The program includes outreach that informs the dismantlers of the need for removal of mercury switches and provides training and guidance for removing mercury switches; [40 CFR 63.10885(b)(2)(i)]~~
~~2) The program has a goal to remove at least 80 percent of mercury switches from motor vehicle scrap the scrap provider processes. Although a program approved under 40 CFR 63.10885(b)(2) may require only the removal of convenience light switch mechanisms, the U.S. EPA will credit all documented and verifiable mercury containing components removed from motor vehicle scrap (such as sensors in anti-locking brake systems, security systems, active ride control, and~~

Commented [CS19]: The NOCS has already been submitted.

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

other applications) when evaluating progress towards the 80 percent goal; and [40 CFR 63.10885(b)(2)(ii)]

3) The program sponsor agrees to submit progress reports to the U.S. EPA no less frequently than once every year that provide the number of mercury switches removed or the weight of mercury recovered from the switches, the estimated number of vehicles processed, an estimate of the percent of mercury switches recovered, and certification that the recovered mercury switches were recycled at facilities with permits as required under the rules implementing subtitle C of RCRA (40 CFR parts 261 through 265 and 268). The progress reports must be based on a database that includes data for each program participant; however, data may be aggregated at the State level for progress reports that will be publicly available. The U.S. EPA may change the approval status of a program or portion of a program (e.g., at the State level) following 90-days notice based on the progress reports or on other information. [40 CFR 63.10885(b)(2)(iii)]

4) The permittee shall develop and maintain onsite a plan demonstrating the manner through which the facility is participating in the EPA-approved program. [40 CFR 63.10885(b)(2)(iv)]

A. The plan shall include facility-specific implementation elements, corporate-wide policies, and/or efforts coordinated by a trade association as appropriate for each facility. [40 CFR 63.10885(b)(2)(iv)(A)]

B. The permittee shall provide in the plan documentation of direction to appropriate staff to communicate to suppliers throughout the scrap supply chain the need to promote the removal or mercury switches from end-of-life vehicles. Upon the request of the U.S. EPA or the Division, the permittee shall provide examples of materials that are used for outreach to suppliers, such as letters, contract language, policies for purchasing agents, and scrap inspection protocols. [40 CFR 63.10885(b)(2)(iv)(B)]

C. The permittee shall conduct periodic inspections or other means of corroboration to ensure that scrap providers are aware of the need for and are implementing appropriate steps to minimize the presence of mercury in scrap from end-of life vehicles. [40 CFR 63.10885(b)(2)(iv)(C)]

iii. The permittee shall certify in the notification of compliance status and maintain records of documentation that the only materials from motor vehicles in the scrap are materials recovered for their specialty alloy (including, but not limited to, chromium, nickel, molybdenum, or other alloys) content (such as certain exhaust systems) and, based on the nature of the scrap and purchase specifications, that the type of scrap is not reasonably expected to contain mercury switches. [40 CFR 63.10885(b)(3)]

iv. For scrap not subject to the requirements in 401 CFR 63.10885(b)(1) through (3), the permittee shall certify in the notification of compliance status and maintain records of documentation that this scrap does not contain motor vehicle scrap. [40 CFR 63.10885(b)(4)]

c. The permittee shall comply with the pollution prevention management practices in 40 CFR 63.10885 and 63.10886, the requirements in 40 CFR 63.10895(b) through (e), and the requirements in 40 CFR 63.10896 through 63.10900. [40 CFR 63.10895(a)]

Formatted: Body Text, Justified, Indent: Left: 1.49", Right: 0.49", Space Before: 4.5 pt, No bullets or numbering, Tab stops: Not at 1.49"

Commented [CS20]: See above comment.

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

d. The permittee shall prepare and operate at all times according to a written operation and maintenance (O&M) plan for each control device. The permittee shall maintain a copy of the O&M plan at the facility and make it available for review upon request. At a minimum, each plan shall contain the following information: [40 CFR 63.10896(a)]
   i. General facility and contact information; [40 CFR 63.10896(a)(1)]
   ii. Positions responsible for inspecting, maintaining, and repairing emissions control devices which are used to comply with 40 CFR 63, Subpart ZZZZZ; [40 CFR 63.10896(a)(2)]
   iii. Description of items, equipment, and conditions that will be inspected, including an inspection schedule for the items, equipment, and conditions. For baghouses that are equipped with bag leak detection systems, the O&M plan shall include the site- specific monitoring plan required in 40 CFR 63.10897(d)(2). [40 CFR 63.10896(a)(3)]
   iv. Identity and estimated quantity of the replacement parts that will be maintained in inventory; and [40 CFR 63.10896(a)(4)]
   v. Procedures for operating and maintaining a CPMS in accordance with manufacturer's specifications. [40 CFR 63.10896(a)(5)]

e. The permittee may use any other O&M, preventative maintenance, or similar plan which addresses the requirements in 40 CFR 63.10896(a)(1) through (5) to demonstrate compliance with the requirements for an O&M plan. [40 CFR 63.10896(b)]

f. The permittee shall not exceed the yearly operating limitations listed in the table above on a rolling 12-month basis. [401 KAR 51:017]

g. The permittee shall prepare and maintain for ~~EU03, EU04,~~ EU05, EU06, ~~EU11, EU12,~~ EU15, EU16, EU18, EU44, EU45, EU46, and EU47~~, and EU52,~~ within 90 days of startup, a good combustion and operation practices plan (GCOP) that defines, measures and verifies the use of operational and design practices determined as BACT for minimizing CO, VOC, PM, PM_{10}, and $PM_{2.5}$ emissions. Any revisions requested by the Division shall be made and the plan shall be maintained on site. The permittee shall operate according to the provisions of this plan at all times, including periods of startup, shutdown, and malfunction. The plan shall be incorporated into the plant standard operating procedures (SOP) and shall be made available for the Division's inspection. The plan shall include, but not be limited to: [401 KAR 51:017]
   i. A list of combustion optimization practices and a means of verifying the practices have occurred.
   ii. A list of combustion and operation practices to be used to lower energy consumption and a means of verifying the practices have occurred.
   iii. A list of the design choices determined to be BACT and verification that designs were implemented in the final construction.

Compliance Demonstration Method:
Refer to **4. Specific Monitoring Requirements, 5. Specific Recordkeeping Requirements, 6. Specific Reporting Requirements,** and **7. Specific Control Equipment Operating Conditions.**

Commented [CS21]: This requirement only applies to the melting furnaces. See definition of "control device" that states "...generated by a metal melting furnace"

Commented [CS22R21]: This should be removed from this section.

Commented [CS23]: This requirement only applies to the melting furnaces. See definition of "control device" that states "...generated by a metal melting furnace

Commented [CS24]: EU03 and EU04 will not be installed

Commented [CS25]: EU11 and EU12 will not be installed

Commented [CS26]: EU52 does not use fuel.

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

h. The permittee shall operate a capture and collection system for each emission unit listed above to maintain negative pressure in the foundry. Each capture and collection system employed shall meet accepted engineering standards, such as those published by the American Conference of Governmental Industrial Hygienists. ~~Except for EU60, EU61, EU62, EU64, EU65, EU66, and EU67, each emission unit listed above shall maintain 100% capture efficiency at all times. EU60, EU61, EU62, EU64, EU65, EU66, and EU67 shall maintain 98% capture efficiency at all times.~~ [401 KAR 51:017]

~~i. The permittee shall ensure that the building removal efficiency for PM, PM_{10}, and $PM_{2.5}$ in the buildings that house the emission units listed above is at least 90%. [401 KAR 51:017]~~

Compliance Demonstration Method:
Compliance with **1. Operating Limitations (h)** and **(i)** shall be demonstrated by completing the testing in **3. Testing Requirements (i),** submitting the report required in **6. Specific Reporting Requirements (c),** and monitoring according to **7. Specific Control Reqirements (d).**

~~j.~~i. The permittee shall install ~~a~~two natural gas burners along the conveyor downstream of each~~the~~ pouring station (EU50 and EU51). These burners shall be oriented such that they ignite the vents of the mold assemblies in the event that they are not already burning. [401 KAR 51:017]

Formatted: Not Highlight

Formatted: Not Highlight

~~k.~~j. The permittee shall operate and maintain the BACT control devices identified in the table above at all times that any associated process vented to the control device is operating. [401 KAR 51:017]

2. Emission Limitations:

a. The permittee shall not discharge to the atmosphere fugitive emissions from foundry operations that exhibit opacity greater than 20 percent (6-minute average), except for one 6-minute average per hour that does not exceed 30 percent. [40 CFR 63.10895(e); 401 KAR 51:017]

i. For the purposes of 40 CFR 63, Subpart ZZZZZ and the limit above: *Fugitive emissions* means any pollutant released to the atmosphere that is not discharged through a system of equipment that is specifically designed to capture pollutants at the source, convey them through ductwork, and exhaust them using forced ventilation. *Fugitive emissions* include pollutants released to the atmosphere through windows, doors, vents, or other building openings. *Fugitive emissions* also include pollutants released to the atmosphere through other general building ventilation or exhaust systems not specifically designed to capture pollutants at the source. [40 CFR 63.10906]

Compliance Demonstration Method:
Refer to **3. Testing Requirements, 4. Specific Monitoring Requirements, 5. Specific Recordkeeping Requirements, 6. Specific Reporting Requirements,** and **7. Specific Control Equipment Operating Conditions.**

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

b. The permittee shall not cause, suffer, allow, or permit any continuous (persisting more than 3 minutes) emission of particulate matter into the open air from a control device or stack associated with any affected facility which is equal to or greater than twenty (20) percent opacity, as measured by U.S. EPA Reference Method 9. [401 KAR 59:010, Section 3(1)(a); 401 KAR 51:017]

Compliance Demonstration Method:
Refer to **4. Monitoring Requirements(d)** for opacity compliance demonstration.

c. For emissions from a control device or stack no person shall cause, suffer, allow or permit the emission into the open air of particulate matter from any affected facility which is in excess of the following: [401 KAR 59:010, Section 3(2)]

i. For process weight rates of 0.50 ton/hr or less: 2.34 lb/hr
ii. For process weight rates up to 30 tons/hr: $E'_{PM_j} = 3.59P_j^{0.62}$
iii. For process weight rates greater than 30 tons/hr: $E'_{PM_j} = 17.31P_j^{0.16}$

Where:
j = Emission Unit;
E'_{PM_j} = The allowable particulate emission rate for unit j in pounds/hour;
P_j = The average process weight rate in tons/hour

Compliance Demonstration Method:
Compliance with the hourly particulate emission limitations in 401 KAR 59:010, Section 3(2) is assumed when compliance with the limitations in **2. Emission Limitations(d)** and **SECTION D(5)** is demonstrated and natural gas is used as fuel for combustion sources.

d. The permittee shall not emit to the atmosphere total PM, PM_{10}, and $PM_{2.5}$ emissions greater than the following: [401 KAR 51:017]

Emission Unit	Description	BACT Control Device	BACT for PM	BACT for PM_{10}	BACT for $PM_{2.5}$

Commented [CS30]: EU03 is not installed

Compliance Demonstration Method:
Refer to **3. Testing Requirements, 4. Specific Monitoring Requirements, 5. Specific Recordkeeping Requirements, 6. Specific Reporting Requirements,** and **7. Specific Control Equipment Operating Conditions.**

g. Refer to **SECTION D** for group PSD limits for PM, PM_{10}, $PM_{2.5}$, VOC, and CO, and source-wide HAP emission limitations.

3. Testing Requirements:

a. ~~The permittee shall conduct a performance test to demonstrate initial compliance with the applicable emissions limits for each building or structure housing foundry operations that is subject to the opacity limit for fugitive emissions in 40 CFR 63.10895(e). The permittee shall conduct the test within 180 days of startup and report the results in the notification of compliance status. [40 CFR 63.10898(a)]~~

Commented [CS31]: Initial compliance demonstration has been completed.

b. The permittee shall conduct each opacity test for fugitive emissions according to the requirements in 40 CFR 63.6(h)(5) and Table 1 to 40 CFR 63, Subpart ZZZZZ. [40 CFR 63.10898(h)]

c. The permittee shall conduct subsequent performance tests to demonstrate compliance with the opacity limit in 40 CFR 63.10895(e) no less frequently than every 6 months and each time the permittee makes a process change likely to increase fugitive emissions. [40 CFR 63.10898(i)]

d. ~~In the performance test report, the permittee shall certify that the capture system operated normally during the performance test. [40 CFR 63.10898(j)]~~

Commented [CS32]: Performance test is not required for these emission units.

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

~~c.~~d. For fugitive emissions from buildings or structures housing any iron and steel foundry emissions sources subject to opacity limit in 40 CFR 63.10895(e), the permittee shall: [40 CFR 63, Subpart ZZZZZ, Table 1(2)]

i. Using a certified observer, conduct each opacity test according to EPA Method 9 (40 CFR part 60, appendix A-4) and 40 CFR 63.6(h)(5). [40 CFR 63, Subpart ZZZZZ, Table 1(2)(a)]

1) The certified observer may identify a limited number of openings or vents that appear to have the highest opacities and perform opacity observations on the identified openings or vents in lieu of performing observations for each opening or vent from the building or structure. Alternatively, a single opacity observation for the entire building or structure may be performed, if the fugitive release points afford such an observation. [40 CFR 63, Subpart ZZZZZ, Table 1(2)(a)(i)]

2) During testing intervals when PM performance tests, if applicable, are being conducted, conduct the opacity test such that the opacity observations are recorded during the PM performance tests. [40 CFR 63, Subpart ZZZZZ, Table 1(2)(a)(ii)]

ii. As alternative to Method 9 performance test, conduct visible emissions test by Method 22 (40 CFR part 60, appendix A-7). The test is successful if no visible emissions are observed for 90 percent of the readings over 1 hour. If VE is observed greater than 10 percent of the time over 1 hour, then the facility must conduct another performance test as soon as possible, but no later than 15 calendar days after the Method 22 test, using Method 9 (40 CFR part 60, appendix A-4). [40 CFR 63, Subpart ZZZZZ, Table 1(2)(b)]

1) The observer may identify a limited number of openings or vents that appear to have the highest visible emissions and perform observations on the identified openings or vents in lieu of performing observations for each opening or vent from the building or structure. Alternatively, a single observation for the entire building or structure may be performed, if the fugitive release points afford such an observation. [40 CFR 63, Subpart ZZZZZ, Table 1(2)(b)(i)]

2) During testing intervals when PM performance tests, if applicable, are being conducted, conduct the visible emissions test such that the observations are recorded during the PM performance tests. [40 CFR 63, Subpart ZZZZZ, Table 1(2)(b)(ii)]

~~f.~~e. Except as provided in 401 KAR 50:045, performance tests used to demonstrate compliance with 401 KAR 59:010, Section 3 shall be conducted according to the following methods. Kentucky Methods 50 and 150(F-1) and other methods are filed by reference in 401 KAR 50:015. [401 KAR 59:010, Section 4]

i. Reference Method 5 for the emission rates of particulate matter and the associated moisture content. [401 KAR 59:010, Section 4(1)]

ii. Reference Method 1 for sample and velocity traverses. [401 KAR 59:010, Section 4(2)]

iii. Reference Method 2 for velocity and volumetric flow rate. [401 KAR 59:010, Section 4(3)]

iv. Reference Method 3 for gas analysis. [401 KAR 59:010, Section 4(4)]

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

v. Reference Method 9 for opacity of continuous emissions. [401 KAR 59:010, Section 4(5)]
vi. For Reference Method 5, Reference Method 1 shall be used to select the sampling site and the number of traverse sampling points. The sampling time for each run shall be at least sixty (60) minutes and the minimum sample volume shall be 0.85 dscm (thirty (30) dscf) except that smaller sampling time or volumes, when necessitated by process variables or other factors, may be approved by the Cabinet. [401 KAR 59:010, Section 4(7)]

~~g.~~f. Pursuant to 401 KAR 59:005, Section 2(2) and 401 KAR 50:045, Section 1, performance testing using the Reference Methods specified in 401 KAR 50:015 shall be conducted as required by the Division.

~~h.~~g. For emission unit EU53, the permittee shall perform individual initial performance testing according to 401 KAR 50:055 and every 5 years thereafter. This testing shall be used to demonstrate compliance with the individual BACT limitations in **2. Emission Limitations.** The testing shall also develop emission factors in pounds of pollutant per ton of gray iron for CO and VOC according to following test methods: [401 KAR 51:017]
~~i.~~h. 40 CFR 60, Appendix A, Method 10 for CO;
ii. 40 CFR 60, Appendix A, Method 25 for VOC;
iii. Or an alternate test method as approved by the Division.

i. The permittee shall, within 180 days of permit issuance~~after startup of the emissions units listed above~~, verify the direction of airflow through both the largest building wall opening closest to each process and the largest opening of each hood and exhaust pickup point, is inward using a smoke tube and the following procedures: [401 KAR 51:017]
i. The direction of airflow shall be monitored for at least 1 hour, with checks made no more than 10 minutes apart.
ii. The ~~fan RPM and~~ volumetric flow rate shall be monitored during the test.

~~j.~~i. Refer to **SECTION D** for group testing requirements.

4. Specific Monitoring Requirements:

~~a. The permittee shall make monthly inspections of the equipment that is important to the performance of the total capture system (i.e., pressure sensors, dampers, and damper switches). This inspection shall include observations of the physical appearance of the equipment (e.g., presence of holes in the ductwork or hoods, flow constrictions caused by dents or accumulated dust in the ductwork, and fan erosion). The permittee shall repair any defect or deficiency in the capture system as soon as practicable, but no later than 90 days. The permittee shall record the date and results of each inspection and the date of repair of any defect or deficiency. [40 CFR 63.10897(e)]~~

Commented [CS33]: This paragraph is only applicable to metal melting operations.

~~b. The permittee shall install, operate, and maintain each CPMS or other measurement device according to the O&M plan. The permittee shall record all information needed to document conformance with these requirements. [40 CFR 63.10897(f)]~~

Commented [CS34]: This paragraph is only applicable to metal melting operations

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

~~e.~~a. ~~In the event of an exceedance of an established emissions limitation (including an operating limit), the permittee shall restore operation of the emissions source (including the control device and associated capture system) to its normal or usual manner or operation as expeditiously as practicable in accordance with good air pollution control practices for minimizing emissions. The response shall include minimizing the period of any startup, shutdown or malfunction and taking any necessary corrective actions to restore normal operation and prevent the likely recurrence of the exceedance. The permittee shall record the date and time correction action was initiated, the correction action taken, and the date corrective action was completed. [40 CFR 63.10897(g)]~~

Commented [CS35]: This is only applicable to metal melting furnaces.

~~d. The permittee shall perform a qualitative visual observation of the opacity of emissions at each stack daily and maintain a log of the observations. If visible emissions from a stack are seen (not including condensed water in the plume), then an inspection of process/control equipment shall be initiated and corrective action taken. If visible emissions are present after the corrective action, the process(s) shall be shut down and shall not operate again until repairs have been made that result in no visible emissions from the process(s) during operation. In lieu of shutting the process(s) down, the permittee may determine the opacity using Reference Method 9. If the opacity limit is not exceeded, the process(s) may continue to operate. [401 KAR 51:017]~~

Commented [CS36]: There are no fugitive egress point stacks and the baghouse has a BLDS installed, therefore a daily qualitative visual observation should not be required

~~e.~~b. For each emission unit listed above, the permittee shall monitor the following parameters:

i. Monthly and 12-month rolling total hours of operation;
ii. Monthly and 12-month rolling total throughput;
iii. The monthly ~~3-hour average~~ emission rate in ton/yr~~lb/hr~~ of PM, PM_{10}, $PM_{2.5}$, CO, and VOC for each process with an emission limitation in **2. Emission Limitations(d), (e),** or **(f),** calculated monthly.
iv. The 12-month rolling total emission rate in ton/yr of PM, PM_{10}, $PM_{2.5}$, CO, and VOC for each process with an emission limitation in **2. Emission Limitations(d), (e),** or **(f),** calculated monthly.

~~f.~~c. For each emission unit listed above ~~except EU60, EU61, EU62, EU64, EU65, EU66, and EU67,~~ the permittee shall perform individual inspections during each day~~shift~~ and certify that no visible fugitive emissions are detected from each applicable building opening. [401 KAR 51:017]

Commented [CS37]: Stack emissions are addressed via the BLDS. This has been modified to include documentation of any fugitive emissions from the applicable building.

~~g.~~d. Refer to **SECTION E.**

5. Specific Recordkeeping Requirements:

a. As required by 40 CFR 63.10(b)(1) and as applicable, the permittee shall maintain files of all information (including all reports and notifications) for at least 5 years following the date of each occurrence, measurement, maintenance, corrective action, report, or record. At a minimum, the most recent 2 years of data shall be retained on site. The remaining 3 years of data may be retained off site. Such files may be maintained on microfilm, on a computer, on computer floppy disks, on magnetic tape disks, or on microfiche. [40 CFR 63.10899(a)]

Commented [CS38]: This has been added due to the only required record for the above operations is the semiannual determination of building opacity.

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

b. In addition to the records required by 40 CFR 63.10, the permittee shall keep records of the information specified in 40 CFR 63.10899(b)(1) through (13). [40 CFR 63.10899(b)]

i. The permittee shall keep records of the written materials specifications according to 40 CFR 63.10885(a) and records that demonstrate compliance with the requirements for restricted metallic scrap in 40 CFR 63.10885(a)(1) and/or for the use of general scrap in 40 CFR 63.10885(a)(2) and for mercury in 40 CFR 63.10885(b)(1) through (3), as applicable. The permittee shall keep records documenting compliance with 40 CFR 63.10885(b)(4) for scrap that does not contain motor vehicle scrap. [40 CFR 63.10899(b)(1)]

ii. If the permittee is subject to the requirements for a site-specific plan for mercury under 40 CFR 63.10885(b)(1), the permittee shall: [40 CFR 63.10899(b)(2)]

1) Maintain records of the number of mercury switches removed or the weight of mercury recovered from the switches and properly managed, the estimated number of vehicles processed, and an estimate of the percent of mercury switches recovered; and [40 CFR 63.10899(b)(2)(i)]

2) Submit semiannual reports of the number of mercury switches removed or the weight of mercury recovered from the switches and properly managed, the estimated number of vehicles processed, an estimate of the percent of mercury switches recovered, and a certification that the recovered mercury switches were recycled at RCRA permitted facilities. The semiannual reports shall include a certification that the permittee has conducted periodic inspections or taken other means of corroboration as required under 40 CFR 63.10885(b)(1)(ii)(C). The permittee shall identify which option in 40 CFR 63.10885(b) applies to each scrap provider, contract, or shipment. The permittee may include this information in the semiannual compliance reports required under 40 CFR 63.10899(c). [40 CFR 63.10899(b)(2)(ii)]

iii. If the permittee is subject to the option for approved mercury programs under 40 CFR 63.10885(b)(2), the permittee shall maintain records identifying each scrap provider and documenting the scrap provider's participation in an approved mercury switch removal program. If the scrap provider is a broker, the permittee shall maintain records identifying each of the broker's scrap suppliers and documenting the scrap supplier's participation in an approved mercury switch removal program. [40 CFR 63.10899(b)(3)]

iv. The permittee shall keep records of monthly metal melt production for each calendar year. [40 CFR 63.10899(b)(6)]

v. The permittee shall keep a copy of the operation and maintenance plan as required by 40 CFR 63.10896(a) and records that demonstrate compliance with plan requirements. [40 CFR 63.10899(b)(7)]

vi. The permittee shall keep records for bag leak detection systems as follows: [40 CFR 63.10899(b)(9)]

1) Records of the bag leak detection system output; [40 CFR 63.10899(b)(9)(i)]

2) Records of bag leak detection system adjustments, including the date and time of the adjustment, the initial bag leak detection system settings, and the final bag leak detection system settings; and [40 CFR 63.10899(b)(9)(ii)]

Commented [CS39]: This section is applicable to the furnaces.

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

~~3) The date and time of all bag leak detection system alarms, and for each valid alarm, the time corrective action was initiated, the corrective action taken, and the date on which corrective action was completed. [40 CFR 63.10899(b)(9)(iii)]~~

~~vii. The permittee shall keep records of capture system inspections and repairs as required by 40 CFR 63.10897(e). [40 CFR 63.10899(b)(10)]~~

~~viii. The permittee shall keep records demonstrating conformance with the specifications for the operation of CPMS as required by 40 CFR 63.10897(f). [40 CFR 63.10899(b)(11)]~~

~~ix. The permittee shall keep records of corrective action(s) for exceedances and excursions as required by 40 CFR 63.10897(g). [40 CFR 63.10899(b)(12)]~~

~~x. The permittee shall record the results of each inspection and maintenance required by 40 CFR 63.10897(a) for PM control devices in a logbook (written or electronic format). The permittee shall keep the logbook onsite and make the logbook available to the Division upon request. The permittee shall keep records of the information specified in 40 CFR 63.10899(b)(13)(i) through (iii). [40 CFR 63.10899(b)(13)]~~

~~1) The date and time of each recorded action for a fabric filter, the results of each inspection, and the results of any maintenance performed on the bag filters. [40 CFR 63.10899(b)(13)(i)]~~

~~c.~~b. The permittee shall record the occurrence, duration, cause and any corrective action taken for any incident or malfunction that occurs that causes or might cause an exceedance of the particulate emission or opacity standard when an emission unit is in operation. A log of any required Method 9 observations and any required qualitative visual observations shall be kept and made available for inspection.

~~d.~~c. For each emission unit listed above, the permittee shall maintain records of the following:

i. Monthly and 12-month rolling total hours of operation;
ii. Monthly and 12-month rolling total throughput;
iii. The monthly ~~3-hour average~~ emission rate of PM, PM_{10}, $PM_{2.5}$, CO, and VOC for each process with an emission limitation in **2. Emission Limitations(d), (e),** or **(f)** calculated monthly.
iv. The 12-month rolling total emission rate of PM, PM_{10}, $PM_{2.5}$, CO, and VOC for each process with an emission limitation in **2. Emission Limitations(d), (e),** or **(f)** calculated monthly.
v. SDSs for all materials used.

~~e.~~d. The permittee shall maintain a copy of the GCOP plan required by **1. Operating Limitations (g)** as well as any revisions. [401 KAR 51:017]

~~f.~~e. The permittee shall maintain records of any time that ~~EU03, EU04,~~ EU05, EU06, ~~EU11, EU12~~, EU15, EU16, EU18, EU44, EU45, EU46, and EU47~~, or EU52~~ was not operated according to the GCOP plan required by **1. Operating Limitations (g)** with a description of the situation and actions taken to remedy the issue. [401 KAR 51:017]

Commented [CS40]: EU03, EU04, EU11, and EU12 were not installed. EU52 is not a source of combustion emissions.

~~g.~~f. The permittee shall maintain records of the calculations required in **SECTION D**.

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

6. Specific Reporting Requirements:

a. The permittee shall submit semiannual compliance reports to the Division according to the requirements in 40 CFR 63.10(e). The reports shall include, at a minimum, the following information as applicable: [40 CFR 63.10899(c)]

i. Summary information on the number, duration, and cause (including unknown cause, if applicable) of excursions or exceedances, as applicable, and the corrective action taken; [40 CFR 63.10899(c)(1)]

ii. Summary information on the number, duration, and cause (including unknown cause, if applicable) for monitor downtime incidents (other than downtime associated with zero and span or other calibration checks, if applicable); and [40 CFR 63.10899(c)(2)]

iii. Summary information on any deviation from the pollution prevention management practices in 40 CFR 63.10885 and 63.10886 and the operation and maintenance requirements 40 CFR 63.10896 and the corrective action taken. [40 CFR 63.10899(c)(3)]

~~b. The notification of compliance status required by 40 CFR 63.9(h) shall include this certification of compliance, signed by a responsible official: [40 CFR 63, Subpart ZZZZZ, Table 4]~~

~~i. "This facility has prepared, and will operate by, written material specifications for metallic scrap according to 40 CFR 63.10885(a)(1)" and/or "This facility has prepared, and will operate by, written material specifications for general iron and steel scrap according to 40 CFR 63.10885(a)(2)."~~

~~ii. "This facility has prepared, and will operate by, written material specifications for the removal of mercury switches and a site-specific plan implementing the material specifications according to 40 CFR 63.10885(b)(1)" and/or "This facility participates in and purchases motor vehicles scrap only from scrap providers who participate in a program for removal of mercury switches that has been approved by the EPA Administrator according to 40 CFR 63.10885(b)(2) and have prepared a plan for participation in the EPA approved program according to 40 CFR 63.10885(b)(2)(iv)" and/or "The only materials from motor vehicles in the scrap charged to a metal melting furnace at this facility are materials recovered for their specialty alloy content in accordance with 40 CFR 63.10885(b)(3) which are not reasonably expected to contain mercury switches" and/or "This facility complies with the requirements for scrap that does not contain motor vehicle scrap in accordance with 40 CFR 63.10885(b)(4)."~~

~~iii. "This facility has prepared and will operate by an operation and maintenance plan according to 40 CFR 63.10896(a)."~~

~~iv. "This facility has prepared and will operate by a site-specific monitoring plan for each bag leak detection system and submitted the plan to the Division for approval according to 40 CFR 63.10897(d)(2)."~~

~~c. The permittee shall, within 90 days after conducting the initial performance test, submit the design information and analysis, with supporting documentation, demonstrating that each capture and collection system (hood, canopy, open entrance, etc.) meets accepted engineering standards, such as those published by the American Conference of~~

Commented [CS41]: This should be either a facility requirement or under the metal melting furnaces. Also this language needs to change based on the latest revision of Subpart ZZZZZ.

Commented [CS42]: The NOCS has already been submitted.

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

~~Governmental Industrial Hygienists, and is capable of meeting the capture efficiency requirement in **1. Operating Limitations**~~ **(h).** [401 KAR 51:017]

7. Specific Control Equipment Operating Conditions:

a. For EU17, EU19, EU20, EU21, EU35A, EU35B, EU57, ~~EU58~~ and EU63, the permittee shall install, calibrate (if applicable), maintain and operate, according to manufacturer's specifications, bin vent filters designed to achieve the BACT limits in **2. Emission Limitations(d)**. The permittee shall make the bin vent filter manufacturer's specifications~~se records~~ available for inspection by the Division. [401 KAR 51:017]

Commented [CS43]: EU58 was not installed.

b. For all emission units, other than those identified in **7.a. Specific Control Equipment Operating Conditions(a)**, the permittee shall install, calibrate (if applicable), maintain and operate, according to manufacturer's specifications, fabric filters designed to achieve the BACT limits in **SECTION D(5)**. The permittee shall make the fabric filter manufacturer's specifications~~se records~~ available for inspection by the Division. [401 KAR 51:017]

c. Refer to **SECTION E** for control device requirements pursuant to 40 CFR 63, Subpart ZZZZZ and 401 KAR 51:017.

d. The permittee shall operate the control devices associated with each emission unit at all times that the emission unit is operating. [401 KAR 51:017]

e. The permittee shall install, operate, and maintain a Sulfuric Acid Scrubber for control of amine gas emitted from the PUCB Core Machines (EU39-EU42)~~core machines~~. [401 KAR 51:017]

f. For each baghouse, the permittee shall continuously monitor the inlet volumetric flow rate in the stack, and maintain it at 80% or above the level measured during the testing required by **3. Testing Requirements (i)**.

g. The permittee shall install, calibrate (if applicable), maintain and operate, according to manufacturer's specifications, a monitoring device (differential pressure gauges or manometers) to determine the pressure drop across each baghouse, at a minimum, once a day~~shift~~ during the operation of the unit. A permanent label displaying the operating range established for each baghouse shall be posted next to the selected instrument. [401 KAR 51:017]

8. Alternate Operating Scenarios:

Refer to **Section H**.

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

Coating Operations

Emission Group 06 – Coating

Emission Unit 68 (EU68) **Paint Line #3**
Booth #1 Description:
Model: Sturm Maschinenbau ZS16
Estimated Start of Construction: September 2018~~August 2016~~
Maximum Capacity: 7.22~~28.9~~ lb post-induction coating (coating and thinner)/hr Controls: Paint Booth Filter (CU14)

Emission Unit 69 (EU69) **Paint Line ~~Booth~~ #2**
Description:
Model: Sturm Maschinenbau ZS16
Estimated Start of Construction: November 2017~~August 2016~~
Maximum Capacity: 7.22~~28.9~~ lb post-induction coating (coating and thinner)/hr Controls: Paint Booth Filter (CU15)

~~**Emission Unit 70 (EU70) Paint Booth #3**~~
~~**Description:**~~
~~Model: Sturm Maschinenbau ZS16~~
~~Estimated Start of Construction: March 2019~~
~~Maximum Capacity: 28.9 lb post-induction coating/hr~~
~~Controls: Paint Booth Filter (CU16)~~

Emission Unit 71 (EU71) **Paint Line #1~~Booth #4~~**
Description:
Model: Sturm Maschinenbau ZS16
Estimated Start of Construction: March 2017~~August 2016~~
Maximum Capacity: 3.54~~2.38~~ lb pre-induction coating/hr Controls: Paint Booth Filter (CU17)

Description: Three~~Four~~ (34) paint booths that apply coatings to finished parts. EU 68-69~~70~~ apply a zinc paint to each part, EU71 applies a zinc solution. Each of these paint booths are equipped with electrostatic spray nozzles that achieve at least 70% transfer efficiency.

APPLICABLE REGULATIONS:
401 KAR 51:017, Prevention of significant deterioration of air quality.
401 KAR 59:010, New process operations.
401 KAR 59:225, New miscellaneous metal parts and products surface coating operations.

STATE-ORIGIN REQUIREMENTS:
401 KAR 63:020, Potentially hazardous matter or toxic substances, applicable with respect to each affected facility which emits or may emit Xylene, Methanol, or Zinc.

Formatted: Right: 3.16"
Formatted: Right: 3.66"
Formatted: Right: 3.1"
Commented [CS44]: EU70 has not been installed.
Formatted: Right: 2.97"
Formatted: Right: 3.43"

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

PRECLUDED REGULATIONS:

40 CFR 63, Subpart HHHHHH, National Emission Standards for Hazardous Air Pollutants: Paint Stripping and Miscellaneous Surface Coating Operations at Area Sources.

1. **Operating Limitations:**
   a. The permittee shall only use coatings with a VOC content of less than three and five- tenths (3.5) lb/gal of coating (0.42 kg/l), excluding water or exempt solvent or both, delivered to applicators associated with air or forced air-dried items or items subject to outdoor or harsh exposure or extreme environmental conditions. [401 KAR 59:225, Section 6(1)(b); 401 KAR 51:017]

   b. The permittee shall only use post-induction coatings with a solids content of less than 0.87 lb/lb of coating delivered to the applicators. [401 KAR 51:017]

   c. The permittee shall only use pre-induction coatings with a solids content of less than 0.35 lb/lb of coating delivered to the applicators. [401 KAR 51:017]

   d. The amount of exempt solvent shall be subtracted from the amount of coatings, just like water, with the ultimate value of interest being the mass of VOC per unit volume of coating less exempt solvent or water or both. [401 KAR 59:225, Section 4(6)]

   e. The permittee shall not use any spray-applied coating that contains any individual compounds of chromium (Cr), lead (Pb), manganese (Mn), nickel (Ni), or cadmium (Cd) that are an Occupational Safety and Health Administration (OSHA)-defined carcinogen as specified in 29 CFR 1910.1200(d)(4) at a concentration greater than 0.1 percent by mass, or greater than 1.0 percent by mass for any other individual compound of chromium (Cr), lead (Pb), manganese (Mn), nickel (Ni), or cadmium (Cd). For the purpose of determining whether materials used contain compounds of chromium (Cr), lead (Pb), manganese (Mn), nickel (Ni), or cadmium (Cd), the permittee may rely on formulation data provided by the manufacturer or supplier, such as the material safety data sheet (MSDS), as long as it represents each compound of chromium (Cr), lead (Pb), manganese (Mn), nickel (Ni), or cadmium (Cd) in the material that is present at 0.1 percent by mass or more for compounds of chromium (Cr), lead (Pb), manganese (Mn), nickel (Ni), or cadmium (Cd) that are OSHA-defined carcinogens as specified in 29 CFR 1910.1200(d)(4) and at 1.0 percent by mass or more for other compounds of chromium (Cr), lead (Pb), manganese (Mn), nickel (Ni), or cadmium (Cd). [To preclude 40 CFR 63, Subpart HHHHHH]

   f. The permittee shall limit the throughput through EU68, EU69~~, and EU70~~ to a combined 63.25~~138.9~~ tons/yr of post-induction coating (coating and thinner) on a rolling 12-month basis. [401 KAR 51:017]

   g. The permittee shall limit the throughput through EU71 to 15.5 tons/yr of pre-induction coating on a rolling 12-month basis. [401 KAR 51:017]

Commented [CS45]: Coating is not air dried.

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

h. The permittee shall limit thinner usage to a combined 12.886.9 tons/yr of thinner on a rolling 12-month basis. [401 KAR 51:017]

i. The permittee shall~~, within 90 days of startup, develop and~~ maintain and implement a work practice plan to minimize VOC emissions from the storage, mixing, and conveying of coatings, thinners, and cleaning materials used in, and waste materials generated by, all coating operations. The plan shall specify practices and procedures to ensure that, at a minimum, the following elements are implemented: [401 KAR 51:017]
   i. All VOC-containing coatings, thinners, cleaning materials, and waste materials shall be stored in closed containers.
   ii. The risk of spills of VOC-containing coatings, thinners, cleaning materials, and waste materials shall be minimized.
   iii. VOC-containing coatings, thinners, cleaning materials, and waste materials shall be conveyed from one location to another in closed containers or pipes.
   iv. Mixing vessels which contain VOC-containing coatings and other materials shall be closed except when adding to, removing, or mixing the contents.
   v. Emissions of VOC shall be minimized during cleaning of storage, mixing, and conveying equipment.

j. The permittee shall ensure that each paint booth capture system achieves 100% efficiency. The permittee shall demonstrate this by meeting the following requirements: [401 KAR 51:017]
   i. Performing testing according to **3. Testing Requirements (f).**
   ii. Ensuring all coatings and thinners used in the coating operation are applied within the capture system, and coating solvent flash-off and coating curing and drying occurs within the capture system. For example, this criterion is not met if parts enter the open shop environment when being moved between a spray booth and a curing oven.
   iii. The direction of the air flow at all times shall be into the enclosure; and either
      1) The average facial velocity of air through all natural draft openings in the enclosure shall be at least 200 feet per minute; or
      2) The pressure drop across the enclosure shall be at least 0.007 inch water, as established in Method 204 of appendix M to 40 CFR part 51.

k. The permittee shall maintain the facial velocity of air flow through all natural draft openings or the pressure drop at or above the facial velocity limit or pressure drop limit, and maintain the direction of air flow into the enclosure at all times. [401 KAR 51:017]

Compliance Demonstration Method:
Refer to **3. Testing Requirements, 4. Specific Monitoring Requirements, 5. Specific Recordkeeping Requirements, 6. Specific Reporting Requirements**, and **7. Specific Control Equipment Operating Conditions.**

2. Emission Limitations:

a. The permittee shall not cause, suffer, allow, or permit any visible emission of particulate matter into the open air from a control device or stack associated with any affected facility which is equal to or greater than twenty (20) percent opacity for more than three

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

(3) minutes, as measured by U.S. EPA Reference Method 9. [401 KAR 59:010, Section 3(1)(a); 401 KAR 51:017]

Compliance Demonstration Method:
Refer to **4. Monitoring Requirements(c)** for opacity compliance demonstration.

b. For emissions from a control device or stack no person shall cause, suffer, allow or permit the emission into the open air of particulate matter from any affected facility which is in excess of the following: [401 KAR 59:010, Section 3(2)]
   i. For process weight rates of 0.50 ton/hr or less: 2.34 lb/hr
   ii. For process weight rates up to 30 tons/hr: $E'_{PM_j} = 3.59P_j^{0.62}$
   iii. For process weight rates greater than 30 tons/hr: $E'_{PM_j} = 17.31P_j^{0.16}$

   Where:
   j = Emission Unit;
   E'_{PM_j} = The allowable particulate emission rate for unit j in pounds/hour;
   P_j = The average process weight rate in tons/hour

Compliance Demonstration Method:
Compliance with the hourly particulate emission limitations in 401 KAR 59:010, Section 3(2) is assumed when compliance with the limitations in **2. Emission Limitations(c)** is demonstrated.

c. For EU68 and, EU69~~, and EU70,~~ the permittee shall not cause or contribute to combined total emissions of PM, PM_{10}, and $PM_{2.5}$ that, on a rolling 12-month basis, equal or exceed 0.202~~363~~ tons of PM, PM_{10}, or $PM_{2.5}$ per year. [401 KAR 51:017]

d. For EU71, the permittee shall not cause or contribute to total emissions of PM, PM_{10}, and $PM_{2.5}$ that, on a rolling 12-month basis, equal or exceed 1.133~~0.016~~ tons of PM, PM_{10}, or $PM_{2.5}$ per year. [401 KAR 51:017]

e. For EU68 and, EU69~~, and EU70~~, the permittee shall not cause or contribute to combined total emissions of VOC (including contributions from thinner usage) that, on a rolling 12-month basis, equal or exceed 19.425~~25.7~~ tons of VOC per year. [401 KAR 51:017]

f. EU71, the permittee shall not cause or contribute to total emissions of VOC that, on a rolling 12-month basis, equal or exceed 3.244~~1.94~~ tons of VOC per year. [401 KAR 51:017]

Compliance Demonstration Method:
Refer to **3. Testing Requirements**, **4. Specific Monitoring Requirements**, **5. Specific Recordkeeping Requirements**, and **7. Specific Control Equipment Operating Conditions.**

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

g. The source is in compliance with 401 KAR 63:020 based on the emission rates of toxics and hazardous air pollutants given in the application and supplemental information submitted by the source.
h. Refer to **SECTION D** for source-wide HAP emission limitations.

3. Testing Requirements:

a. If deemed necessary by the Cabinet, the Cabinet shall obtain samples of the coatings used at an affected facility to verify that the coatings meet the requirements in 401 KAR 59:225, Section 6. Appendix A to 40 CFR 60, Method 24, which has been incorporated by reference in 401 KAR 50:015, shall be used as applicable to determine compliance of the coatings unless the Cabinet determines that other methods would be more appropriate. [401 KAR 59:225, Section 4(4)]

b. Except as provided in 401 KAR 50:045, performance tests used to demonstrate compliance with 401 KAR 59:010, Section 3 shall be conducted according to the following methods. Kentucky Methods 50 and 150(F-1) and other methods are filed by reference in 401 KAR 50:015. [401 KAR 59:010, Section 4]
   i. Reference Method 5 for the emission rates of particulate matter and the associated moisture content. [401 KAR 59:010, Section 4(1)]
   ii. Reference Method 1 for sample and velocity traverses. [401 KAR 59:010, Section 4(2)]
   iii. Reference Method 2 for velocity and volumetric flow rate. [401 KAR 59:010, Section 4(3)]
   iv. Reference Method 3 for gas analysis. [401 KAR 59:010, Section 4(4)]
   v. Reference Method 9 for opacity of continuous emissions. [401 KAR 59:010, Section 4(5)]
   vi. For Reference Method 5, Reference Method 1 shall be used to select the sampling site and the number of traverse sampling points. The sampling time for each run shall be at least sixty (60) minutes and the minimum sample volume shall be 0.85 dscm (thirty (30) dscf) except that smaller sampling time or volumes, when necessitated by process variables or other factors, may be approved by the Cabinet. [401 KAR 59:010, Section 4(7)]

c. For emission units EU68, EU69~~, EU70,~~ and EU71, the permittee shall perform individual initial performance testing according to 401 KAR 50:055 and every 5 years thereafter. This testing shall be used to demonstrate compliance with the individual BACT limitations in **2. Emission Limitations** and **1. Operating Limitations(a)**. This testing shall also develop inlet and outlet emission factors in pounds of pollutant per pound of coating for PM, PM_{10}, $PM_{2.5}$, and VOC according to following test methods: [401 KAR 51:017]
   i. 40 CFR 60, Appendix A, Method 5 for PM;
   ii. 40 CFR 51, Appendix M, Method 201A for PM_{10} and $PM_{2.5}$;
   iii. 40 CFR 60, Appendix A, Method 24 for VOC;
   iv. Or an alternate test method as approved by the Division.

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

d. The permittee shall determine the mass fraction of organic HAP for each material used, on a monthly basis or when the formulation of the coating changes, by using one of the options below:
   i. The permittee may use 40 CFR 63, Appendix A, Method 311 for determining the mass fraction of organic HAP.
   ii. For coatings, the permittee may use Method 24 to determine the mass fraction of nonaqueous volatile matter and use that value as a substitute for mass fraction of organic HAP.
   iii. The permittee may rely on information other than that generated by the test methods specified above, such as manufacturer's formulation data, if it represents each organic HAP that is present at 0.1 percent by mass or more for OSHA-defined carcinogens, as specified in 29 CFR 1910.1200(d)(4), and at 1.0 percent by mass or more for other compounds. If there is a disagreement between such information and results of a test conducted according to the terms above, then the test method results will take precedence, unless after consultation, the facility demonstrates to the satisfaction of the Division that the facility's data are correct. If a range of values is given for the mass fraction, the permittee shall use the maximum of the range in the calculation of emissions.

e. The permittee shall determine the density of each material used during the month from test results using ASTM Method D1475-98 (Reapproved 2003), "Standard Test Method for Density of Liquid Coatings, Inks, and Related Products" or information from the supplier or manufacturer of the material. If there is disagreement between ASTM Method D1475-98 (Reapproved 2003) test results and the supplier's or manufacturer's information, the test results will take precedence unless after consultation, the facility demonstrates to the satisfaction of the Division that the facility's data are correct.

f. The permittee shall demonstrate that the capture system meets the criteria in Method 204 of appendix M to 40 CFR part 51 for a PTE.

~~g. The permittee shall perform a mass balance test to determine the mass transfer percentage of solids for each paint booth.~~

~~h.~~g. Pursuant to 401 KAR 59:005, Section 2(2) and 401 KAR 50:045, Section 1, performance testing using the Reference Methods specified in 401 KAR 50:015 shall be conducted as required by the Division.

4. Specific Monitoring Requirements:

a. The permittee shall determine the volume in gallons of each material used during each month by measurement or usage records.

b. The permittee shall monitor and record the direction of air flow, and either:
   i. The facial velocity of air through all natural draft openings according to the following requirements for each flow measurement device, or:

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

1) The permittee shall locate a flow sensor in a position that provides a representative flow measurement in the duct from each capture device in the emission capture system to the add-on control device.
2) The permittee shall reduce swirling flow or abnormal velocity distributions due to upstream and downstream disturbances.
3) The permittee shall conduct a flow sensor calibration check at least semiannually.
4) The permittee shall, at least monthly, inspect components for integrity, electrical connections for continuity, and mechanical connections for leakage.

ii. The pressure drop across the enclosure according to the following requirements for each flow measurement device:
1) The permittee shall locate the pressure tap(s) in a position that provides a representative measurement of the pressure drop across each opening that is being monitored.
2) The permittee shall minimize or eliminate pulsating pressure, vibration, and internal and external corrosion.
3) The permittee shall check pressure tap pluggage monthly~~daily~~.
4) The permittee shall~~, using an inclined manometer with a measurement sensitivity of 0.0002 inch water,~~ check gauge calibration ~~quarterly~~ and transducer calibration quarterly~~monthly~~.
5) The permittee shall conduct calibration checks any time the sensor exceeds the manufacturer's specified maximum operating pressure range or install a new pressure sensor.
6) The permittee shall, at least monthly, inspect components for integrity, electrical connections for continuity, and mechanical connections for leakage.

c. The permittee shall perform a qualitative visual observation of the opacity of emissions at each stack daily and maintain a log of the observations. If visible emissions from a stack are seen (not including condensed water in the plume), then an inspection of process/control equipment shall be initiated and corrective action taken. If visible emissions are present after the corrective action, the process shall be shut down and shall not operate again until repairs have been made that result in no visible emissions from the process during operation. In lieu of shutting the process down, the permittee may determine the opacity using Reference Method 9. If the opacity limit is not exceeded, the process may continue to operate.

d. For each emission unit listed above, the permittee shall monitor the following parameters:
i. Monthly and 12-month rolling total hours of operation;
ii. Monthly and 12-month rolling total coating throughput;
iii. Monthly and 12-month rolling thinner usage;
~~iv.~~ Monthly and 12-month rolling total emissions of PM, PM_{10}, ~~and~~ $PM_{2.5}$, VOC and HAP in tons/yr, ~~calculated monthly according to the following equation:~~

~~$E_{xi} = [(\frac{P_{ij} * 30\% * EF_{jx}}{2000}) * (1 - B_{jx})]$~~

Commented [CS46]: Method of emission calculations should be as provided in the permit application.

Formatted: List Paragraph, Right: 0.49", Space Before: 0 pt, Numbered + Level: 3 + Numbering Style: i, ii, iii, … + Start at: 1 + Alignment: Left + Aligned at: 0.99" + Indent at: 1.24", Tab stops: 1.24", Left

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

$$T_{jx} = \sum_{i=1}^{12} E_{xi}$$

Formatted: Indent: Left: 1.24", Space Before: 3.55 pt

Where:

i = Month;

j = Emission Unit;

x = Pollutant (PM, PM_{10}, or $PM_{2.5}$)

E_x = The actual average monthly emission rate of pollutant x from unit j during month i in tons of x per month;

P_i = The actual specific throughput through unit j during month i in pounds of coating used per month;

EF_j = The corresponding solids content of the coating used in emission unit j or the emission factor determined by a representative performance test conducted according to the requirements of 401 KAR 50:045, within the last five (5) years, in pounds of pollutant x per pound of paint used;

B_{jx} = Control efficiency (%) of any control device at emission unit j for pollutant x;

T_{jx} = Total 12-month rolling emissions of pollutant x at emission unit j in tons of pollutant x per year;

30% = 1 - Transfer efficiency (70%) of the electrostatic spray nozzles.

v. 12-month rolling total emissions of VOC and HAP, in tons/yr, calculated monthly according to the following equation:

$$E_{xi} = \left(\frac{P_{ij} * EF_{jx}}{2000}\right)$$

$$T_{jx} = \sum_{i=1}^{12} E_{xi}$$

Where:

i = Month;

j = Emission Unit;

x = Pollutant (VOC or HAP)

E_{xi} = The actual average monthly emission rate of pollutant x from unit j during month i in tons of x per month;

P_{ij} = The actual specific throughput through unit j during month i in pounds of coating or thinner used per month;

EF_{jx} = The corresponding uncontrolled emission factor for pollutant x as approved by the most recent permitting action for emission unit j or the emission factor determined by a representative performance test conducted according to the requirements of 401 KAR 50:045, within the last five (5) years, in pounds of pollutant x per pound of paint used;

T_j = Total 12-month rolling emissions of pollutant x at emission unit j in tons of

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

~~pollutant x per year~~

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

5. Specific Recordkeeping Requirements:

a. Daily records shall be maintained by the source for the most recent two (2) year period. These records shall be made available to the Cabinet or the U.S. EPA upon request. The records shall include, but not be limited to, the following: [401 KAR 59:225, Section 4(8)]
   i. Applicable administrative regulation number; [401 KAR 59:225, Section 4(8)(a)]
   ii. Application method and substrate type; [401 KAR 59:225, Section 4(8)(b)]
   iii. Amount and type of adhesive, coating (including catalyst and reducer for multicomponent coatings), or solvent used at each point of application, including exempt compounds; [401 KAR 59:225, Section 4(8)(c)]
   iv. The VOC content as applied in each adhesive, coating, or solvent; [401 KAR 59:225, Section 4(8)(d)]
   v. The date for each application for adhesive, coating, or solvent; [401 KAR 59:225, Section 4(8)(e)]
   vi. The amount of surface preparation, cleanup, or washup solvent (including exempt compounds) used and the VOC content of each; and [401 KAR 59:225, Section 4(8)(f)]
   vii. Oven temperature, if applicable. [401 KAR 59:225, Section 4(8)(g)]

b. The permittee shall record the occurrence, duration, cause and any corrective action taken for any incident or malfunction that occurs that causes or might cause an exceedance of the particulate emission or opacity standard when an emission unit is in operation. A log of Method 9 observations and qualitative visual observations shall be kept and made available for inspection.

c. For each emission unit listed above, the permittee shall maintain records of the following:
   i. Monthly and 12-month rolling total hours of operation;
   ii. Monthly and 12-month rolling total throughput;
   iii. Monthly and 12-month rolling thinner usage;
   iv. Monthly and 12-month rolling total emissions of PM, PM_{10}, $PM_{2.5}$, VOC, and HAP in tons/yr, calculated monthly according to the equation in **4. Specific Monitoring Requirements(b).**
   v. MSDSs for all materials used.

d. The permittee shall maintain records of the following:
   i. A current copy of information provided by materials suppliers or manufacturers, such as manufacturer's formulation data, or test data used to determine the mass fraction of organic HAP, the density and the volume fraction of coating solids for each coating, the mass fraction of organic HAP and the density for each thinner, and the mass fraction of organic HAP for each cleaning material.
   ii. If the permittee conducted testing to determine mass fraction of organic HAP, density, or volume fraction of coating solids, the permittee shall keep a copy of the complete test report.
   iii. If the permittee uses information provided by the manufacturer or supplier of the material that was based on testing, the permittee shall keep the summary sheet of results provided by the manufacturer or supplier.

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

iv. If the permittee uses the results of an analysis conducted by an outside testing lab, the permittee shall keep a copy of the test report. The permittee is not required to obtain the test report or other supporting documentation from the manufacturer or supplier.
v. A record of the name and volume of each cleaning material used during each month.
vi. A record of the mass fraction of HAP and VOC for each cleaning material used during each month.
vii. A record of the density for each cleaning material used during each month.
viii. The data and documentation used to support a determination that the capture system meets the criteria in Method 204 of appendix M to 40 CFR part 51 for a PTE and has a capture efficiency of 100 percent.
ix. Records of the data and calculations used to establish the emission capture and add- on control device operating limits and to document compliance with the operating limitations.
x. Records of the data and calculations used to determine the transfer efficiency for all coatings.
xi. A record of the work practice plans required and documentation that the plans are being implemented on a continuous basis. Appropriate documentation may include operational and maintenance records, records of documented inspections, and records of internal audits.
xii. For each add-on control device and for each continuous parameter monitoring system, a copy of the equipment operating instructions shall be maintained on-site for the life of the equipment in a location readily available to plant operators and inspectors. The permittee may prepare the equipment operating instructions, or they may be provided by the equipment supplier or other third party.

e. Copies of the current work practice plans developed in accordance with **1. Operating Requirements(g)**, as well as plans developed within the preceding 5 years shall be available on-site for inspection and copying by the Division.

f. The permittee shall keep monthly records of the following:
   i. For each coating used, a record of the volume used in each month, the mass fraction HAP content, the mass fraction VOC content, the density, and the volume fraction of solids.
   ii. For each thinner used, a record of the volume used in each month, the mass fraction HAP content, the mass fraction VOC content, and the density.
   iii. A record of the calculation of the HAP and VOC emission rate for all coatings and thinners. This record must include all raw data, algorithms, and intermediate calculations. If these data are maintained as electronic files, the electronic files, as well as any paper copies must be maintained.
   iv. A record, for each month, of the calculation of the average monthly mass HAP and VOC content.

6. Specific Reporting Requirements:
Refer to **SECTION F**.

7. Specific Control Equipment Operating Conditions:

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

a. For all emission units listed above, the permittee shall install, maintain, and operate, according to manufacturer's specifications, fabric filters designed to achieve the BACT limits in **1. Operating Limitations(b)** and **(c)**, and **2. Emission Limitations(c)**. The permittee shall make the manufacturer's specifications~~e~~ records available for inspection by the Division. [401 KAR 51:017]

b. The permittee shall install, calibrate (as applicable), maintain and operate, according to manufacturer's specifications, a monitoring device (differential pressure gauges or manometers) to determine the pressure drop across each paint booth filter, at a minimum, once a day~~shift~~ during the operation of the unit. A permanent label displaying the operating range established for each paint booth shall be posted next to the selected instrument. [401 KAR 51:017]

c. The permittee shall operate the control devices associated with each emission unit at all times that the emission unit is operating. [401 KAR 51:017]

d. The permittee shall install, operate, and maintain each Continuous Parameter Monitoring System (CPMS) for each pressure drop and/or air flow measuring device~~(e.g. each temperature sensor, pressure drop monitor, etc)~~ according to the following: [401 KAR 52:020, Section 10]
   i. The CPMS shall complete a minimum of one cycle of operation for each successive 15-minute period. The permittee shall have a minimum of four equally spaced successive cycles of CPMS operation in 1 hour.
   ii. The permittee shall determine the average of all recorded readings for each successive 3-hour period of the emission capture system ~~and add-on control device operation~~.
   iii. The permittee shall record the results of each inspection, calibration, and validation check of the CPMS.
   iv. The permittee shall maintain the CPMS at all times and have available necessary parts for routine repairs of the monitoring equipment.
   v. The permittee shall operate the CPMS and collect emission capture system and add- on control device parameter data at all times that a controlled coating operation is operating.

e. The permittee shall maintain a log detailing the operation and maintenance of the emission capture systems, add-on control devices, and continuous parameter monitoring systems (CPMS). [401 KAR 51:017]

~~f. The permittee shall develop a written startup, shutdown, and malfunction plan (SSMP) according to the provisions in 40 CFR 63.6(e)(3). The SSMP shall address startup, shutdown, and corrective actions in the event of a malfunction of the emission capture system or the add-on control devices. [401 KAR 51:017]~~

Commented [CS47]: SSM Plan requirements has been removed from the NESHAP General Provisions.

8. Alternate Operating Scenarios:
Refer to **Section H**.

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

Emission Group 07 – Emergency Generators > 500 HP

Emission Unit 72 (EU72) Emergency Generator #1
Description:
Model: Caterpillar #C 27 or equivalent
Estimated Start of Construction: August 2016
Engine Rating: 1050 HP
Controls: None

Emission Unit 73 (EU73) Emergency Generator #2
Description:
Model: Caterpillar #C 27 or equivalent
Estimated Start of Construction: August 2016
Engine Rating: 1050 HP
Controls: None

Emission Unit 74 (EU74) Emergency Generator #3
Description:
Model: Caterpillar #C 4 or equivalent
Estimated Start of Construction: August 2016
Engine Rating: 56 HP
Controls: None

Description: Three diesel fired compression ignition emergency generators: two that generate 750 kW each and one that generates 40 kW. All of these generators have a displacement of less than 30 liters per cylinder.

APPLICABLE REGULATIONS:
401 KAR 51:017, Prevention of significant deterioration of air quality.
401 KAR 60:005, Section 2(2)(dddd) implementing **40 CFR 60, Subpart IIII,** *Standards of Performance for Stationary Compression Ignition Internal Combustion Engines*
401 KAR 63:002, Section 2(4)(eeee) implementing **40 CFR 63, Subpart ZZZZ,** *National Emission Standards for Hazardous Air Pollutants for Stationary Reciprocating Internal Combustion Engines*

Note: D.C. Circuit Court [*Delaware v. EPA*, 785 F. 3d 1 (D.C. Cir. 2015)] has vacated the provisions in 40 CFR 63, Subpart ZZZZ and 40 CFR 60, Subpart IIII that contain the 100-hour exemption for operation of emergency engines for purposes of emergency demand response under 40 CFR 63.6640(f)(2)(ii)-(iii) and 40 CFR 60.4211(f)(2)(ii)-(iii). The D.C. Circuit Court issued the mandate for the vacatur on May 4, 2016.

1. **Operating Limitations:**
   a. The permittee shall meet the requirements of 40 CFR 63, Subpart ZZZZ by meeting the requirements of 40 CFR part 60, Subpart IIII, for compression ignition engines. [40 CFR 63.6590(c)(1)]

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

b. The permittee shall operate and maintain the emission units listed above such that they achieve the emission standards as required in 40 CFR 60.4205 over the entire life of the engine. [40 CFR 60.4206]

c. The permittee shall use diesel fuel that meets the requirements of 40 CFR 80.510(b) for nonroad diesel fuel. [40 CFR 60.4207(b)]

d. The permittee shall install a non-resettable hour meter prior to startup of the engine. [40 CFR 60.4209(a)]

e. The permittee shall comply with the emission standards specified in 40 CFR 60.4205(b) by purchasing an engine certified to the emission standards in 40 CFR 60.4205(b) for the same model year and maximum engine power. The engine shall be installed and configured according to the manufacturer's emission-related specifications, except as permitted in 40 CFR 60.4211(g). [40 CFR 60.4211(c)]

f. The permittee shall operate the emergency stationary ICE according to the requirements in 40 CFR 60.4211(f)(1) through (3). In order for the engine to be considered an emergency stationary ICE under 40 CFR 60, Subpart IIII, any operation other than emergency operation, maintenance and testing, emergency demand response, and operation in non-emergency situations for 50 hours per year, as described in 40 CFR 60.4211(f)(1) through (3), is prohibited. If the permittee does not operate the engine according to the requirements in 40 CFR 60.4211(f)(1) through (3), the engine will not be considered an emergency engine under 40 CFR 60, Subpart IIII and shall meet all requirements for non-emergency engines. [40 CFR 60.4211(f)]
   i. There is no time limit on the use of emergency stationary ICE in emergency situations. [40 CFR 60.4211(f)(1)]
   ii. The permittee may operate the emergency stationary ICE for any combination of the purposes specified in 40 CFR 60.4211(f)(2)(i) through (iii) for a maximum of 100 hours per calendar year. Any operation for non-emergency situations as allowed by 40 CFR 60.4211(f)(3) counts as part of the 100 hours per calendar year allowed by 40 CFR 60.4211(f)(2). [40 CFR 60.4211(f)(2)]
      1) Emergency stationary ICE may be operated for maintenance checks and readiness testing, provided that the tests are recommended by federal, state or local government, the manufacturer, the vendor, the regional transmission organization or equivalent balancing authority and transmission operator, or the insurance company associated with the engine. The permittee may petition the Administrator for approval of additional hours to be used for maintenance checks and readiness testing, but a petition is not required if the permittee maintains records indicating that federal, state, or local standards require maintenance and testing of emergency ICE beyond 100 hours per calendar year. [40 CFR 60.4211(f)(2)(i)]
   iii. Emergency stationary ICE may be operated for up to 50 hours per calendar year in non-emergency situations. The 50 hours of operation in non-emergency situations are counted as part of the 100 hours per calendar year for maintenance and testing and emergency demand response provided in 40 CFR 60.4211(f)(2). Except as provided

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

in 40 CFR 60.4211(f)(3)(i), the 50 hours per calendar year for non-emergency situations cannot be used for peak shaving or non-emergency demand response, or to generate income for a facility to an electric grid or otherwise supply power as part of a financial arrangement with another entity. [40 CFR 60.4211(f)(3)]

1) The 50 hours per year for non-emergency situations can be used to supply power as part of a financial arrangement with another entity if all of the following conditions are met: [40 CFR 60.4211(f)(3)(i)]
   A. The engine is dispatched by the local balancing authority or local transmission and distribution system operator; [40 CFR 60.4211(f)(3)(i)(A)]
   B. The dispatch is intended to mitigate local transmission and/or distribution limitations so as to avert potential voltage collapse or line overloads that could lead to the interruption of power supply in a local area or region. [40 CFR 60.4211(f)(3)(i)(B)]
   C. The dispatch follows reliability, emergency operation or similar protocols that follow specific NERC, regional, state, public utility commission or local standards or guidelines. [40 CFR 60.4211(f)(3)(i)(C)]
   D. The power is provided only to the facility itself or to support the local transmission and distribution system. [40 CFR 60.4211(f)(3)(i)(D)]
   E. The permittee identifies and records the entity that dispatches the engine and the specific NERC, regional, state, public utility commission or local standards or guidelines that are being followed for dispatching the engine. The local balancing authority or local transmission and distribution system operator may keep these records on behalf of the permittee. [40 CFR 60.4211(f)(3)(i)(E)]

g. If the permittee does not install, configure, operate, and maintain the engine and control device according to the manufacturer's emission-related written instructions, or the permittee changes emission-related settings in a way that is not permitted by the manufacturer, the permittee shall demonstrate compliance as follows: [40 CFR 60.4211(g)]
   The permittee shall keep a maintenance plan and records of conducted maintenance and shall, to the extent practicable, maintain and operate the engine in a manner consistent with good air pollution control practice for minimizing emissions. In addition, the permittee shall conduct an initial performance test to demonstrate compliance with the applicable emission standards within 1 year of startup, or within 1 year after an engine and control device is no longer installed, configured, operated, and maintained in accordance with the manufacturer's emission-related written instructions, or within 1 year after the permittee changes emission-related settings in a way that is not permitted by the manufacturer. The permittee shall conduct subsequent performance testing every 8,760 hours of engine operation or 3 years, whichever comes first, thereafter to demonstrate compliance with the applicable emission standards. [40 CFR 60.4211(g)(3)]

~~h. The permittee shall prepare and maintain for EU72, EU73, and EU74, within 90 days of startup, a good combustion and operation practices plan (GCOP) that defines, measures and verifies the use of operational and design practices determined as BACT for~~

Commented [CS48]: This is an emergency generator and the facility is in compliance with the NESHAP and NSPS. Request this be removed.

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

~~minimizing CO, VOC, PM, PM_{10}, and $PM_{2.5}$ emissions. Any revisions requested by the Division shall be made and the plan shall be maintained on site. The permittee shall operate according to the provisions of this plan at all times, including periods of startup, shutdown, and malfunction. The plan shall be incorporated into the plant standard operating procedures (SOP) and shall be made available for the Division's inspection. The plan shall include, but not be limited to: [401 KAR 51:017]~~

~~i. A list of combustion optimization practices and a means of verifying the practices have occurred.~~

~~ii. A list of combustion and operation practices to be used to lower energy consumption and a means of verifying the practices have occurred.~~

~~iii. A list of the design choices determined to be BACT and verification that designs were implemented in the final construction.~~

Compliance Demonstration Method:
Refer to **4. Specific Monitoring Requirements**, **5. Specific Recordkeeping Requirements**, **6. Specific Reporting Requirements**, and **7. Specific Control Equipment Operating Conditions**.

2. Emission Limitations:

a. The permittee shall comply with the emission standards for new nonroad CI engines in 40 CFR 60.4202, for all pollutants, for the same model year and maximum engine power. [40 CFR 60.4205(b)]

b. The engines listed above shall be certified to meet the certification emission standards for new nonroad CI engines for the same model year and maximum engine power in 40 CFR 89.112 and 40 CFR 89.113 for all pollutants. [40 CFR 60.4202(a)(2)]

c. The permittee shall not cause or contribute to emissions that, on an individual basis, exceed the values listed in the table below. [401 KAR 51:017]

Emission Unit (EU)	PM (g/hp-hr)	PM_{10} (g/hp-hr)	$PM_{2.5}$ (g/hp-hr)	CO (g/hp-hr)	VOC (g/hp-hr)
EU72	0.149	0.149	0.149	2.60	4.77
EU73	0.149	0.149	0.149	2.60	4.77
EU74	0.298	0.298	0.298	3.73	3.50

Compliance Demonstration Method:
The permittee shall install, operate, and maintain each engine such that it meets or is certified to meet the emission limits in **2. Emission Limitations(c)**. The permittee shall maintain engine certifications onsite and available for inspection by the Division.

d. Refer to **SECTION D** for source-wide HAP emission limitations.

3. Testing Requirements:

a. If the permittee conducts performance tests pursuant to 40 CFR 60, Subpart IIII, they shall do so according to 40 CFR 60.4212(a) through (e). [40 CFR 60.4212]

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

i. The performance test shall be conducted according to 40 CFR part 1042, subpart F, for stationary CI ICE with a displacement of greater than or equal to 10 liters per cylinder and less than 30 liters per cylinder. [40 CFR 60.4212(a)]
ii. Exhaust emissions from stationary CI ICE that are complying with the emission standards for new CI engines in 40 CFR part 1042 shall not exceed the NTE standards for the same model year and maximum engine power as required in 40 CFR 1042.101(c). [40 CFR 60.4212(e)]

b. Pursuant to 401 KAR 59:005, Section 2(2) and 401 KAR 50:045, Section 1, performance testing using the Reference Methods specified in 401 KAR 50:015 shall be conducted as required by the Division.

4. Specific Monitoring Requirements:

a. For each emission unit listed above, the permittee shall monitor the following parameters:
i. Monthly and 12-month rolling total hours of operation;
ii. Monthly and 12-month rolling total fuel throughput;

5. Specific Recordkeeping Requirements:

a. If the emergency engine does not meet the standards applicable to non-emergency engines in the applicable model year, the permittee shall keep records of the operation of the engine in emergency and non-emergency service that are recorded through the non- resettable hour meter. The permittee shall record the time of operation of the engine and the reason the engine was in operation during that time. [40 CFR 60.4214(b)]

b. For each emission unit listed above, the permittee shall maintain records of the following:
i. Monthly and 12-month rolling total hours of operation;
ii. Monthly and 12-month rolling total fuel throughput;

6. Specific Reporting Requirements:

a. If an emergency stationary CI ICE operates or is contractually obligated to be available for more than 15 hours per calendar year for the purposes specified in 40 CFR 60.4211(f)(2)(ii) and (iii) or operates for the purposes specified in 40 CFR 60.4211(f)(3)(i), the permittee shall submit an annual report according to the requirements in 40 CFR 60.4214(d)(1) through (3). [40 CFR 60.4214(d)]

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

Emission Group 08 – Storage Tanks

Emission Unit 75 (EU75) Gasoline Storage Tank
Description:
Model: Highland's Double-Wall UL-142 or equivalent
Estimated Start of Construction: August 2016
Maximum Capacity: 2,000 gallons
Controls: None

Commented [CS49]: EU75 is not installed.

APPLICABLE REGULATIONS:
401 KAR 51:017, Prevention of significant deterioration of air quality.
40 CFR 63, Subpart CCCCCC, National Emission Standards for Hazardous Air Pollutants for Source Category: Gasoline Dispensing Facilities.

1. Operating Limitations:

a. The permittee shall not process more than 10,000 gallons of gasoline per month. [40 CFR 63.11111(b)]

b. The permittee shall, at all times, operate and maintain any affected source, including associated air pollution control equipment and monitoring equipment, in a manner consistent with safety and good air pollution control practices for minimizing emissions. Determination of whether such operation and maintenance procedures are being used will be based on information available to the Administrator which may include, but is not limited to, monitoring results, review of operation and maintenance procedures, review of operation and maintenance records, and inspection of the source. [40 CFR 63.11115(a)]

c. The permittee shall not allow gasoline to be handled in a manner that would result in vapor releases to the atmosphere for extended periods of time. Measures to be taken include, but are not limited to, the following: [40 CFR 63.11116(a); 401 KAR 51:017]
i. Minimize gasoline spills; [40 CFR 63.11116(a)(1)]
ii. Clean up spills as expeditiously as practicable; [40 CFR 63.11116(a)(2)]
iii. Cover all open gasoline containers and all gasoline storage tank fill-pipes with a gasketed seal when not in use; [40 CFR 63.11116(a)(3)]
iv. Minimize gasoline sent to open waste collection systems that collect and transport gasoline to reclamation and recycling devices, such as oil/water separators. [40 CFR 63.11116(a)(4)]

d. The permittee shall comply with the requirements of 40 CFR 63, Subpart CCCCCC upon startup. [40 CFR 63.11116(c)]

e. Portable gasoline containers that meet the requirements of 40 CFR part 59, subpart F, are considered acceptable for compliance with 40 CFR 63.11116(a)(3). [40 CFR 63.11116(d)]

f.a. The gasoline storage tank (EU75) shall be equipped with a permanent submerged fill pipe. [401 KAR 51:017]

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

~~2. **Emission Limitations:**~~
~~None~~

~~3. **Testing Requirements:**~~
~~Pursuant to 401 KAR 50:045, Section 1, performance testing using the Reference Methods specified in 401 KAR 50:015 shall be conducted as required by the Division.~~

~~4. **Specific Monitoring Requirements:**~~
~~a. For EU75, the permittee shall monitor the monthly and 12-month rolling total throughput;~~

~~5. **Specific Recordkeeping Requirements:**~~
~~a. The permittee shall, upon request by the Division, demonstrate that the monthly throughput is less than the 10,000-gallon threshold level. As specified in 40 CFR 63.11112(b) and (c), recordkeeping to document monthly throughput shall begin upon startup of the affected source. Records required under 40 CFR 63.11111(e) shall be kept for a period of 5 years. [40 CFR 63.11111(e)]~~

~~b. The permittee shall keep applicable records and submit reports as specified in 40 CFR 63.11125(d) and 40 CFR 63.11126(b). [40 CFR 63.11115(b)]~~

~~c. The permittee shall keep records as specified in 40 CFR 63.11125(d)(1) and (2). [40 CFR 63.11125(d)]~~
~~i. Records of the occurrence and duration of each malfunction of operation (i.e., process equipment) or the air pollution control and monitoring equipment. [40 CFR 63.11125(d)(1)]~~
~~ii. Records of actions taken during periods of malfunction to minimize emissions in accordance with 40 CFR 63.11115(a), including corrective actions to restore malfunctioning process and air pollution control and monitoring equipment to its normal or usual manner of operation. [40 CFR 63.1125(d)(2)]~~

~~d. For EU75, the permittee shall maintain records of the monthly and 12-month rolling total throughput.~~

~~6. **Specific Reporting Requirements:**~~
~~a. The permittee is not required to submit notifications or reports as specified in 40 CFR 63.11125, 40 CFR 63.11126, or 40 CFR 63, Subpart A, but the permittee shall have records available within 24 hours of a request by the Division to document the gasoline throughput. [40 CFR 63.11116(b)]~~

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

Emission Group 08 – Storage Tanks

Emission Unit 756 (EU756) Diesel Storage Tank
Description:
Estimated Start of Construction: July 2019~~August 2016~~ Maximum Capacity: 2,000 gallons
Controls: None

APPLICABLE REGULATIONS:
401 KAR 51:017, Prevention of significant deterioration of air quality.

1. **Operating Limitations:**
   The diesel storage tank (EU76) shall be equipped with a permanent submerged fill pipe. [401 KAR 51:017]

2. **Emission Limitations:**
   None

3. **Testing Requirements:**
   Pursuant to 401 KAR 50:045, Section 1, performance testing using the Reference Methods specified in 401 KAR 50:015 shall be conducted as required by the Division.

4. **Specific Monitoring Requirements:**
   None

5. **Specific Recordkeeping Requirements:**
   None

6. **Specific Reporting Requirements:**
   None

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

Emission Group 09 – Roads
Description: Paved Roads within the PSD-prescribed source boundary. This includes emissions from trailer-truck (industrial) traffic only.
Estimated Start of Construction: September ~~August~~
2016 Controls: Vacuum sweeping

Emission Unit 76 (EU76) **Paved Roadways**

Description:
Length: 0.43 miles
Hours of Operation: 8760 hours/yr

APPLICABLE REGULATIONS:
401 KAR 51:017, Prevention of significant deterioration of air quality.
401 KAR 63:010, Fugitive emissions.

1. **Operating Limitations:**
   a. The permittee is authorized to operate 0.43 miles of paved roadways (EU76). [401 KAR 51:017]

   b. The permittee shall not cause, suffer, or allow any material to be handled, processed, transported, or stored; a building or its appurtenances to be constructed, altered, repaired, or demolished, or a road to be used without taking reasonable precaution to prevent particulate matter from becoming airborne. Such reasonable precautions shall include, when applicable, but not be limited to the following: [401 KAR 63:010, Section 3(1)]
      i. Application and maintenance of asphalt, oil, water, or suitable chemicals on roads, materials stockpiles, and other surfaces which can create airborne dusts; [401 KAR 63:010, Section 3(1)(b)]
      ii. Covering, at all times when in motion, open bodied trucks transporting materials likely to become airborne; [401 KAR 63:010, Section 3(1)(d)]
      iii. The maintenance of paved roadways in a clean condition; [401 KAR 63:010, Section 3(1)(e)]
      iv. The prompt removal of earth or other material from a paved street which earth or other material has been transported thereto by trucking or earth moving equipment or erosion by water. [401 KAR 63:010, Section 3(1)(f)]

2. **Emission Limitations:**
   a. ***Fugitive Emission Standard***: The permittee shall not cause or permit the discharge of visible fugitive dust emissions beyond the lot line of the property on which the emissions originate. [401 KAR 63:010, Section 3(2)]

   b. Refer to **SECTION D**.

3. **Testing Requirements:**
   Testing shall be conducted at such times as may be required by the Cabinet in accordance with 401 KAR 50:045.

SECTION B - EMISSION UNITS, EMISSION POINTS, APPLICABLE REGULATIONS, AND OPERATING CONDITIONS (CONTINUED)

4. **Specific Monitoring Requirements:**
   Refer to **SECTION F** for general monitoring requirements.

5. **Specific Recordkeeping Requirements:**
   The permittee shall keep records of the dates that vacuum sweeping occurred according to **7. Specific Control Equipment Operating Conditions** and these records shall be made available to the Division upon request. Refer to **SECTION F** for general recordkeeping requirements.

6. **Specific Reporting Requirements:**
   Refer to **SECTION F** for general reporting requirements.

7. **Specific Control Equipment Operating Conditions:**
   The permittee shall vacuum sweep the pavement at least weekly, except during recent rain events, or as needed in the event of a spill. [401 KAR 51:017]

SECTION C - INSIGNIFICANT ACTIVITIES

The following listed activities have been determined to be insignificant activities for this source pursuant to 401 KAR 52:020, Section 6. Although these activities are designated as insignificant the permittee must comply with the applicable regulation. Process and emission control equipment at each insignificant activity subject to an opacity standard shall be inspected monthly and a qualitative visible emissions evaluation made. Results of the inspection, evaluation, and any corrective action shall be recorded in a log.

Description	Generally Applicable Regulation

There are no listed insignificant activities at this facility.

SECTION D - SOURCE EMISSION LIMITATIONS AND TESTING REQUIREMENTS

1. As required by Section 1b of the *Cabinet Provisions and Procedures for Issuing Title V Permits* incorporated by reference in 401 KAR 52:020, Section 26; compliance with annual emissions and processing limitations contained in this permit, shall be based on emissions and processing rates for any twelve (12) consecutive months.

2. PM, PM_{10}, $PM_{2.5}$, CO, VOC, and HAP emissions, measured by applicable reference methods, or an equivalent or alternative method specified in 40 C.F.R. Chapter I, or by a test method specified in the state implementation plan shall not exceed the respective limitations specified herein.

SOURCEWIDE HAP LIMITS:

3. The permittee shall not cause or contribute to source-wide combined HAP emissions that equal or exceed 25 tons/year based on a 12-month rolling total as calculated monthly by the most recent permit application methodology.~~weekly by the following equation:~~ [Self-imposed to preclude major source status for HAP]

~~$$0.0284M_i + 0.0589B_i + 0.0211S_i + (EF_{NG} * N_i) + (0.138EF_D * D_i) + [(EF_{C1} * C_{1_i}) + (EF_{C2} * C_{2_i})] = X_i$$~~

~~$$\sum_{i=1}^{52} X_i \leq 25\ TPY$$~~

~~Where:~~

~~i = Week;~~

~~M_i = Weekly source-wide process rate for week i in tons of metal/week;~~

~~B_i = Weekly source-wide process rate for week i in pounds of binder used/week; S_i = Weekly source-wide process rate for week i in tons of shot used/week;~~

~~EF_{NG} = Sum of HAP emission factors for the combustion of Natural Gas from AP-42, Table 1.4-3 in pounds of HAP/MMscf;~~

~~N_i = Weekly source-wide natural gas usage during week i in MMscf/week;~~

~~EF_D = Sum of HAP emission factors for the combustion of Diesel fuel from AP-42, Table 3.4-3 and 3.4-4 in pounds of HAP/MMBtu;~~

~~D_i = Weekly source-wide diesel usage during week i in gallons/week;~~

~~EF_{C1} = Concentration of HAP in the pre-induction coating from the manufacturer's SDS or the emission factor determined by a representative performance test conducted according to the requirements of 401 KAR 50:045, within the last five (5) years, in pounds of HAP per pound of coating*;~~

~~C_{1i} = Weekly source-wide process rate for week i in pounds of pre-induction coating used/week;~~

~~EF_{C2} = Concentration of HAP in the post-induction coating from the manufacturer's SDS or the emission factor determined by a representative performance test conducted according to the requirements of 401 KAR 50:045, within the last five (5) years, in pounds of HAP per pound of coating*;~~

~~C_{2i} = Weekly source-wide process rate for week i in pounds of post-induction coating used/week;~~

3. ~~X_i = Source-wide total HAP emissions in tons/week~~.

Formatted: List Paragraph, Right: 0.48", Space Before: 0 pt, Numbered + Level: 1 + Numbering Style: 1, 2, 3, … + Start at: 1 + Alignment: Left + Aligned at: 0.49" + Indent at: 0.74", Tab stops: 0.74", Left

Formatted: List Paragraph, Left, Numbered + Level: 1 + Numbering Style: 1, 2, 3, … + Start at: 1 + Alignment: Left + Aligned at: 0.49" + Indent at: 0.74", Tab stops: 0.74", Left

Formatted: List Paragraph, Left, Right: 0.48", Line spacing: single, Numbered + Level: 1 + Numbering Style: 1, 2, 3, … + Start at: 1 + Alignment: Left + Aligned at: 0.49" + Indent at: 0.74", Tab stops: 0.74",

SECTION D - SOURCE EMISSION LIMITATIONS AND TESTING REQUIREMENTS (CONTINUED)

~~*Note: If the manufacturer's SDS is used for coating emission calculations and a range of values is given, the permittee shall use the maximum of the range.~~
~~Note: The constants given in the equation above are combined emission factors for the single process unit they are multiplied by. (e.g. lb HAP/ton of metal)~~

4. The permittee shall not cause or contribute to source-wide Xylene emissions that equal or exceed 10 tons/year based on a 12-month rolling total as calculated monthly ~~weekly~~ by the most recent permit application methodology~~following equation~~: [Self-imposed to preclude major source status for HAP]

~~$$0.0011B_i + (0.138EF_D * D_i) + [(EF_{C1} * C_{1_i}) + (EF_{C2} * C_{2_i})] = X_i$$~~

~~$$\sum_{i=1}^{52} X_i \leq 10\ TPY$$~~

~~Where:~~
~~i = Week;~~

~~B_i = Weekly source-wide process rate for week i in pounds of binder used/week;~~
~~EF_D = Xylene emission factor for the combustion of Diesel fuel from AP-42, Table 3.4-3 in pounds of Xylene/MMBtu;~~
~~D_i = Weekly source-wide diesel usage during week i in gallons/week;~~
~~EF_{C1} = Concentration of Xylene in the pre-induction coating from the manufacturer's SDS or the emission factor determined by a representative performance test conducted according to the requirements of 401 KAR 50:045, within the last five (5) years, in pounds of Xylene per pound of coating*;~~
~~C_{1i} = Weekly source-wide process rate for week i in pounds of pre-induction coating used/week;~~
~~EF_{C2} = Concentration of Xylene in the post-induction coating from the manufacturer's SDS or the emission factor determined by a representative performance test conducted according to the requirements of 401 KAR 50:045, within the last five (5) years, in pounds of Xylene per pound of coating*;~~
~~C_{2i} = Weekly source-wide process rate for week i in pounds of post-induction coating used/week;~~
~~X_i = Source-wide total Xylene emissions in tons/week.~~
~~*Note: If the manufacturer's SDS is used for coating emission calculations and a range of values is given, the permittee shall use the maximum of the range.~~
~~Note: The constants given in the equation above are combined emission factors for the single process unit they are multiplied by. (e.g. lb HAP/pound of binder)~~

SECTION D - SOURCE EMISSION LIMITATIONS AND TESTING REQUIREMENTS (CONTINUED)

5. The permittee shall not allow the emissions exiting the following control devices to exceed the following: [401 KAR 51:017]

Control Device (Stack)	Emission Units Controlled	Type of Control and Pollutants Controlled	BACT for PM	BACT for PM_{10}	BACT for $PM_{2.5}$

Note: Refer to **Section H for alternate operating scenarios.

Compliance Demonstration

The permittee shall conduct performance testing on CU01, CU06, CU08, and CU11 to demonstrate initial compliance with the BACT limits listed above. The testing shall be performed according to the requirements of 401 KAR 50:055, and repeated every 5 years. The permittee shall use 40 CFR 60, Appendix A, Method 5 for PM, 40 CFR 51, Appendix M, Method 201A/202 for PM_{10} and $PM_{2.5}$. ~~This testing shall also determine emission factors for each group of units in pounds per MMscf of natural gas used, ton of metal poured, number of parts produced, or other appropriate unifying units as approved by the Division, for use in the equation below. This testing shall be repeated for each group of units after the remaining units constructed during Phase 2 within the group are completed and operational.~~

Continuous compliance will be demonstrated by use of the bag leak detection system required in **SECTION E,** meeting the throughput limits for each process in **SECTION B**, and calculating the monthly~~lb/hr~~ and rolling 12-month ton/yr emissions using the emission

calculation methodology presented in the air permit application. ~~from each group of units, using the following equations~~:

$$\frac{P_i * F}{h_i} = H_i$$

SECTION D - SOURCE EMISSION LIMITATIONS AND TESTING REQUIREMENTS (CONTINUED)

And:

$$\sum_{i=1}^{12} H_i * \frac{h_i}{2000} = Y$$

Where:

i = Month;

P_i = Monthly throughput for month i in the group of emission units (CU01, CU06, CU08, CU11, and CU13) in units/month;

EF = The corresponding emission factor for PM, PM_{10}, $PM_{2.5}$, CO or VOC as determined using a representative performance test conducted according to the requirements of 401 KAR 50:045, within the last five (5) years, in lb/unit;

h_i = the total number of hours operated during month i;

H_i = total PM, PM_{10}, $PM_{2.5}$, CO or VOC emissions in lb/hr.

Y = Total rolling 12-month yearly emissions in tons/year.

Note: This calculation shall include all emission units that emit PM, PM_{10}, or $PM_{2.5}$ within the group.

6. The permittee shall not allow the emissions exiting the following building vents to exceed the following: [401 KAR 51:017]

Vent	Emission Units Combined	BACT for PM	BACT for PM_{10}	BACT for $PM_{2.5}$	BACT for VOC	BACT for CO
BV1a & BV1b	EU01, EU05, EU06, EU13, EU14, EU18, EU35A, EU35B Uncaptured Emissions from EU07, EU08, EU09, EU10, EU 60, EU61, EU62, EU 64, EU65	0.73 lb/hr; 3.18 ton/yr (combined)	0.39 lb/hr; 1.72 ton/yr (combined)	0.20 lb/hr; 0.87 ton/yr (combined)	0.02 lb/hr; 0.07 ton/yr (combined)	0.25 lb/hr; 1.08 ton/yr (combined)
BV2a & BV2b	EU66, EU67	0.20 lb/hr; 0.88 ton/yr (combined)	0.20 lb/hr; 0.88 ton/yr (combined)	0.12 lb/hr; 0.53 ton/yr (combined)	N/A	N/A

Compliance Demonstration

The permittee shall conduct roof monitor sampling on BV1a & BV1b and BV2a & BV2b, to demonstrate initial compliance with the BACT limits listed above for PM, PM_{10}, $PM_{2.5}$, VOC, and CO. The testing shall be performed according to the requirements of 401 KAR 50:055, and repeated every 5 years. This testing shall also determine emission factors for each group of units in pounds per MMscf of natural gas used, ton of metal poured, number of parts produced, or other appropriate unifying units as approved by the Division, for use in the equation below. This testing shall be repeated for each pair of building vents after the remaining units constructed during Phase 2 within the group are completed and operational.

Commented [BEF50]: This Building Vent is over Fettling on the south side of the Foundry. This Vent is louvered and rendered inoperable.

Commented [BEF51]: This Building Vent is over the Scrap Yard of the Foundry. This Vent is louvered and rendered inoperable.

Commented [BEF52]: This Building Vent is in the center of the Machining Shop. This Vent is louvered and not operated.

Commented [BEF53]: This Building Vent was not installed.

SECTION D - SOURCE EMISSION LIMITATIONS AND TESTING REQUIREMENTS (CONTINUED)

~~Continuous compliance will be demonstrated by meeting the throughput limits for each process in **SECTION B**, and calculating the lb/hr and rolling 12-month ton/yr emissions from each group of units, using the following equations:~~

$$\frac{P_i * EF}{h_i} = H_i$$

~~And:~~

$$\sum_{i=1}^{12} H_i * \frac{h_i}{2000} = Y$$

~~Where:~~
~~i = Month;~~

~~P_i = Monthly throughput for month i in the group of emission units (BV1a & b or BV2a & b) in units/month;~~
~~EF = The corresponding emission factor for PM, PM_{10}, $PM_{2.5}$, CO or VOC as determined using a representative performance test conducted according to the requirements of 401 KAR 50:045, within the last five (5) years, in lb/unit;~~
~~h_i = the total number of hours operated during month i;~~
~~H_i = total PM, PM_{10}, $PM_{2.5}$, CO or VOC emissions in lb/hr. Y = Total rolling 12-month yearly emissions in tons/year.~~
~~Note: This calculation shall include all emission units that emit PM, PM_{10}, $PM_{2.5}$, CO or VOC within the group.~~

~~7.~~6. The permittee shall not allow the emissions exiting the following stacks to exceed the following: [401 KAR 51:017]

Stack or Vent	Emission Units Combined	BACT for VOC	BACT for CO
ST02	EU01, EU04, EU05, EU06, EU07, EU08, EU09, EU10, , EU13, EU15, EU16, EU18~~EU02, EU04, EU07, EU08, EU09, EU10, EU11, EU12, EU15, EU16~~	3.854~~0.14~~ lb/hr; 4.845~~0.61~~ ton/yr	22.044~~2.11~~ lb/hr; 31.849~~9.25~~ ton/yr
ST07	EU22, EU53	13.358 lb/hr; 24.179 ton/yr	25.30 lb/hr ;45.793 ton/yr

Compliance Demonstration

The permittee shall conduct performance testing on ST02, ST07, ST08, and ST09, to demonstrate initial compliance with the BACT limits listed above. The testing shall be performed according to the requirements of 401 KAR 50:055, and repeated every 5 years. The permittee shall use 40 CFR 60, Appendix A, Method 10 for CO and 40 CFR 60, Appendix A, Method 25 for VOC, or an alternate test method as approved by the Division. ~~This testing shall also~~

SECTION D - SOURCE EMISSION LIMITATIONS AND TESTING REQUIREMENTS (CONTINUED)

~~determine emission factors for each group of units in pounds per MMscf of natural gas used, ton of metal poured, number of parts produced, or other appropriate unifying units as approved by the Division, for use in the equation below. This testing shall be repeated for each group of units after the remaining units constructed during Phase 2 within the group are completed and operational.~~

~~Continuous compliance will be demonstrated by meeting the throughput limits for each process in **SECTION B**, and calculating the lb/hr and rolling 12-month ton/yr emissions from each group of units, using the following equations:~~

$$\frac{P_i * EF}{h_i} = H_i$$

~~And:~~

$$\sum_{i=1}^{12} H_i * \frac{h_i}{2000} = Y$$

~~Where:~~
~~i = Month;~~

~~P_i = Monthly throughput for month i in the group of emission units (ST02, ST08, or ST09) in units/month;~~
~~EF = The corresponding emission factor for CO or VOC as determined using a representative performance test conducted according to the requirements of 401 KAR 50:045, within the last five (5) years, in lb/unit;~~
~~h = the total number of hours operated during month i;~~
~~H_i = Total CO or VOC emissions in lb/hr.~~
~~Y = Total rolling 12-month yearly emissions in tons/year.~~
~~Note: This calculation shall include all emission units that emit CO or VOC within the group~~.

SECTION E - SOURCE CONTROL EQUIPMENT REQUIREMENTS

1. Pursuant to 401 KAR 50:055, Section 2(5), at all times, including periods of startup, shutdown and malfunction, owners and operators shall, to the extent practicable, maintain and operate any affected facility including associated air pollution control equipment in a manner consistent with good air pollution control practice for minimizing emissions. Determination of whether acceptable operating and maintenance procedures are being used will be based on information available to the Division which may include, but is not limited to, monitoring results, opacity observations, review of operating and maintenance procedures, and inspection of the source.

2. The following requirements apply to control devices controlling foundry operations, which includes CU01~~, CU06, CU08, and CU11~~.
   a. The permittee shall install, operate, and maintain a bag leak detection system for each negative pressure baghouse or positive pressure baghouse. The permittee shall install, operate, and maintain each bag leak detection system according to the requirements in 40 CFR 63.10897(d)(1) through (3). [40 CFR 63.10897(d)]
      i. Each bag leak detection system shall meet the requirements in 40 CFR 63.10897(d)(1)(i) through (vii). [40 CFR 63.10897(d)(1)]
         1) The system shall be certified by the manufacturer to be capable of detecting emissions of particulate matter at concentrations of 10 milligrams per actual cubic meter (0.00044 grains per actual cubic foot) or less. [40 CFR 63.10897(d)(1)(i)]
         2) The bag leak detection system sensor shall provide output of relative particulate matter loadings and the permittee shall continuously record the output from the bag leak detection system using a strip chart recorder, data logger, or other means. [40 CFR 63.10897(d)(1)(ii)]
         3) The system shall be equipped with an alarm that will sound when an increase in relative particulate loadings is detected over the alarm set point established in the operation and maintenance plan, and the alarm shall be located such that it can be heard by the appropriate plant personnel. [40 CFR 63.10897(d)(1)(iii)]
         4) The initial adjustment of the system shall, at minimum, consist of establishing the baseline output by adjusting the sensitivity (range) and the averaging period of the device, and establishing the alarm set points. If the system is equipped with an alarm delay time feature, the permittee shall also adjust the alarm delay time. [40 CFR 63.10897(d)(1)(iv)]
         5) Following the initial adjustment, the permittee shall not adjust the sensitivity or range, averaging period, alarm set point, or alarm delay time. Except, once per quarter, the permittee may adjust the sensitivity of the bag leak detection system to account for seasonable effects including temperature and humidity according to the procedures in the monitoring plan required by 40 CFR 63.10897(d)(2). [40 CFR 63.10897(d)(1)(v)]
         6) For negative pressure baghouses, induced air baghouses, and positive pressure baghouses that are discharged to the atmosphere through a stack, the bag leak detector sensor shall be installed downstream of the baghouse and upstream of any wet scrubber. [40 CFR 63.10897(d)(1)(vi)]
         7) Where multiple detectors are required, the system's instrumentation and alarm may be shared among detectors. [40 CFR 63.10897(d)(1)(vii)]
      ii. The permittee shall prepare a site-specific monitoring plan for each bag leak detection system to be incorporated in the O&M plan. The permittee shall operate and maintain each bag leak detection system according to the plan at all times. Each plan shall

Commented [CS54]: This requirement is only for APCD controlling emissions from metal melting furnaces

SECTION E - SOURCE CONTROL EQUIPMENT REQUIREMENTS (CONTINUED)

address all of the items identified in 40 CFR 63.10897(d)(2)(i) through (vi). [40 CFR 63.10897(d)(2)]

1) Installation of the bag leak detection system. [40 CFR 63.10897(d)(2)(i)]
2) Initial and periodic adjustment of the bag leak detection system including how the alarm set-point will be established. [40 CFR 63.10897(d)(2)(ii)]
3) Operation of the bag leak detection system including quality assurance procedures. [40 CFR 63.10897(d)(2)(iii)]
4) Maintenance of the bag leak detection system including a routine maintenance schedule and spare parts inventory list. [40 CFR 63.10897(d)(2)(iv)]
5) How the bag leak detection system output will be recorded and stored. [40 CFR 63.10897(d)(2)(v)]
6) Procedures for determining what corrective actions are necessary in the event of a bag leak detection alarm as required in 40 CFR 63.10897(d)(3). [40 CFR 63.10897(d)(2)(vi)]

iii. In the event that a bag leak detection system alarm is triggered, the permittee shall initiate corrective action to determine the cause of the alarm within 1 hour of the alarm, initiate corrective action to correct the cause of the problem within 24 hours of the alarm, and complete corrective action as soon as practicable, but no later than 10 calendar days from the date of the alarm. The permittee shall record the date and time of each valid alarm, the time that corrective action was initiated, the correction action taken, and the date on which corrective action was completed. Corrective actions may include, but are not limited to: [40 CFR 63.10897(d)(3)]

1) Inspecting the bag house for air leaks, torn or broken bags or filter media, or any other condition that may cause an increase in emissions. [40 CFR 63.10897(d)(3)(i)]
2) Sealing off defective bags or filter media. [40 CFR 63.10897(d)(3)(ii)]
3) Replacing defective bags or filter media or otherwise repairing the control device. [40 CFR 63.10897(d)(3)(iii)]
4) Sealing off a defective baghouse department. [40 CFR 63.10897(d)(3)(iv)]
5) Cleaning the bag leak detection system probe, or otherwise repairing the bag leak detection system. [40 CFR 63.10897(d)(3)(v)]
6) Shutting down the process producing the particulate emissions. [40 CFR 63.10897(d)(3)(vi)]

SECTION F - MONITORING, RECORDKEEPING, AND REPORTING REQUIREMENTS

1. Pursuant to Section 1b-IV-1 of the *Cabinet Provisions and Procedures for Issuing Title V Permits* incorporated by reference in 401 KAR 52:020, Section 26, when continuing compliance is demonstrated by periodic testing or instrumental monitoring, the permittee shall compile records of required monitoring information that include:
   a. Date, place as defined in this permit, and time of sampling or measurements;
   b. Analyses performance dates;
   c. Company or entity that performed analyses;
   d. Analytical techniques or methods used;
   e. Analyses results; and
   f. Operating conditions during time of sampling or measurement.

2. Records of all required monitoring data and support information, including calibrations, maintenance records, and original strip chart recordings, and copies of all reports required by the Division for Air Quality, shall be retained by the permittee for a period of five (5) years and shall be made available for inspection upon request by any duly authorized representative of the Division for Air Quality [Sections 1b-IV-2 and 1a-8 of the *Cabinet Provisions and Procedures for Issuing Title V Permits* incorporated by reference in 401 KAR 52:020, Section 26].

3. In accordance with the requirements of 401 KAR 52:020, Section 3(1)h, the permittee shall allow authorized representatives of the Cabinet to perform the following during reasonable times:
   a. Enter upon the premises to inspect any facility, equipment (including air pollution control equipment), practice, or operation;
   b. To access and copy any records required by the permit:
   c. Sample or monitor, at reasonable times, substances or parameters to assure compliance with the permit or any applicable requirements.

   Reasonable times are defined as during all hours of operation, during normal office hours; or during an emergency.

4. No person shall obstruct, hamper, or interfere with any Cabinet employee or authorized representative while in the process of carrying out official duties. Refusal of entry or access may constitute grounds for permit revocation and assessment of civil penalties.

5. Summary reports of any monitoring required by this permit shall be submitted to the Regional Office listed on the front of this permit at least every six (6) months during the life of this permit, unless otherwise stated in this permit. For emission units that were still under construction or which had not commenced operation at the end of the 6-month period covered by the report and are subject to monitoring requirements in this permit, the report shall indicate that no monitoring was performed during the previous six months because the emission unit was not in operation [Sections 1b-V-1 of the *Cabinet Provisions and Procedures for Issuing Title V Permits* incorporated by reference in 401 KAR 52:020, Section 26].

SECTION F - MONITORING, RECORDKEEPING, AND REPORTING REQUIREMENTS (CONTINUED)

6. The semi-annual reports are due by January 30th and July 30th of each year. All reports shall be certified by a responsible official pursuant to 401 KAR 52:020, Section 23. If continuous emission and opacity monitors are required by regulation or this permit, data shall be reported in accordance with the requirements of 401 KAR 59:005, General Provisions, Section 3(3). All deviations from permit requirements shall be clearly identified in the reports.

7. In accordance with the provisions of 401 KAR 50:055, Section 1, the owner or operator shall notify the Regional Office listed on the front of this permit concerning startups, shutdowns, or malfunctions as follows:
   a. When emissions during any planned shutdowns and ensuing startups will exceed the standards, notification shall be made no later than three (3) days before the planned shutdown, or immediately following the decision to shut down, if the shutdown is due to events which could not have been foreseen three (3) days before the shutdown.
   b. When emissions due to malfunctions, unplanned shutdowns and ensuing startups are or may be in excess of the standards, notification shall be made as promptly as possible by telephone (or other electronic media) and shall be submitted in writing upon request.

8. The owner or operator shall report emission related exceedances from permit requirements including those attributed to upset conditions (other than emission exceedances covered by Section F.7 above) to the Regional Office listed on the front of this permit within 30 days. Deviations from permit requirements, including those previously reported under F.7 above, shall be included in the semiannual report required by F.6 [Sections 1b-V, 3 and 4 of the *Cabinet Provisions and Procedures for Issuing Title V Permits* incorporated by reference in 401 KAR 52:020, Section 26].

9. Pursuant to 401 KAR 52:020, Title V permits, Section 21, the permittee shall annually certify compliance with the terms and conditions contained in this permit, by completing and returning a Compliance Certification Form (DEP 7007CC) (or an alternative approved by the regional office) to the Regional Office listed on the front of this permit and the U.S. EPA in accordance with the following requirements:
   a. Identification of the term or condition;
   b. Compliance status of each term or condition of the permit;
   c. Whether compliance was continuous or intermittent;
   d. The method used for determining the compliance status for the source, currently and over the reporting period.
   e. For an emissions unit that was still under construction or which has not commenced operation at the end of the 12-month period covered by the annual compliance certification, the permittee shall indicate that the unit is under construction and that compliance with any applicable requirements will be demonstrated within the timeframes specified in the permit.
   f. The certification shall be submitted by January 30th of each year. Annual compliance certifications shall be sent to the following addresses:

SECTION F - MONITORING, RECORDKEEPING, AND REPORTING REQUIREMENTS (CONTINUED)

Division for Air Quality	U.S. EPA Region 4
Bowling Green Regional Office	Air Enforcement Branch
2642 Russellville Road	Atlanta Federal Center
Bowling Green, KY 42101	61 Forsyth St. SW
	Atlanta, GA 30303-8960

10. In accordance with 401 KAR 52:020, Section 22, the permittee shall provide the Division with all information necessary to determine its subject emissions within 30 days of the date the Kentucky Emissions Inventory System (KYEIS) emissions survey is mailed to the permittee.

SECTION G - GENERAL PROVISIONS

1. General Compliance Requirements

   a. The permittee shall comply with all conditions of this permit. Noncompliance shall be a violation of 401 KAR 52:020, Section 3(1)(b), and a violation of Federal Statute 42 USC 7401 through 7671q (the Clean Air Act). Noncompliance with this permit is grounds for enforcement action including but not limited to termination, revocation and reissuance, revision or denial of a permit [Section 1a-3 of the *Cabinet Provisions and Procedures for Issuing Title V Permits* incorporated by reference in 401 KAR 52:020, Section 26].

   b. The filing of a request by the permittee for any permit revision, revocation, reissuance, or termination, or of a notification of a planned change or anticipated noncompliance, shall not stay any permit condition [Section 1a-6 of the *Cabinet Provisions and Procedures for Issuing Title V Permits* incorporated by reference in 401 KAR 52:020, Section 26].

   c. This permit may be revised, revoked, reopened and reissued, or terminated for cause in accordance with 401 KAR 52:020, Section 19. The permit will be reopened for cause and revised accordingly under the following circumstances:
      (1) If additional applicable requirements become applicable to the source and the remaining permit term is three (3) years or longer. In this case, the reopening shall be completed no later than eighteen (18) months after promulgation of the applicable requirement. A reopening shall not be required if compliance with the applicable requirement is not required until after the date on which the permit is due to expire, unless this permit or any of its terms and conditions have been extended pursuant to 401 KAR 52:020, Section 12;
      (2) The Cabinet or the United States Environmental Protection Agency (U. S. EPA) determines that the permit must be revised or revoked to assure compliance with the applicable requirements;
      (3) The Cabinet or the U. S. EPA determines that the permit contains a material mistake or that inaccurate statements were made in establishing the emissions standards or other terms or conditions of the permit;
      (4) New requirements become applicable to a source subject to the Acid Rain Program.

      Proceedings to reopen and reissue a permit shall follow the same procedures as apply to initial permit issuance and shall affect only those parts of the permit for which cause to reopen exists. Reopenings shall be made as expeditiously as practicable. Reopenings shall not be initiated before a notice of intent to reopen is provided to the source by the Division, at least thirty (30) days in advance of the date the permit is to be reopened, except that the Division may provide a shorter time period in the case of an emergency.

   d. The permittee shall furnish information upon request of the Cabinet to determine if cause exists for modifying, revoking and reissuing, or terminating the permit; or to determine compliance with the conditions of this permit [Sections 1a- 7 and 8 of the *Cabinet Provisions and Procedures for Issuing Title V Permits* incorporated by reference in 401 KAR 52:020, Section 26].

   e. Emission units described in this permit shall demonstrate compliance with applicable requirements if requested by the Division [401 KAR 52:020, Section 3(1)(c)].

SECTION G - GENERAL PROVISIONS (CONTINUED)

f. The permittee, upon becoming aware that any relevant facts were omitted or incorrect information was submitted in the permit application, shall promptly submit such supplementary facts or corrected information to the permitting authority [401 KAR 52:020, Section 7(1)].

g. Any condition or portion of this permit which becomes suspended or is ruled invalid as a result of any legal or other action shall not invalidate any other portion or condition of this permit [Section 1a-14 of the *Cabinet Provisions and Procedures for Issuing Title V Permits* incorporated by reference in 401 KAR 52:020, Section 26].

h. The permittee shall not use as a defense in an enforcement action the contention that it would have been necessary to halt or reduce the permitted activity in order to maintain compliance [Section 1a-4 of the *Cabinet Provisions and Procedures for Issuing Title V Permits* incorporated by reference in 401 KAR 52:020, Section 26].

i. All emission limitations and standards contained in this permit shall be enforceable as a practical matter. All emission limitations and standards contained in this permit are enforceable by the U.S. EPA and citizens except for those specifically identified in this permit as state-origin requirements. [Section 1a-15 of the *Cabinet Provisions and Procedures for Issuing Title V Permits* incorporated by reference in 401 KAR 52:020, Section 26].

j. This permit shall be subject to suspension if the permittee fails to pay all emissions fees within 90 days after the date of notice as specified in 401 KAR 50:038, Section 3(6) [Section 1a-10 of the *Cabinet Provisions and Procedures for Issuing Title V Permits* incorporated by reference in 401 KAR 52:020, Section 26].

k. Nothing in this permit shall alter or affect the liability of the permittee for any violation of applicable requirements prior to or at the time of permit issuance [401 KAR 52:020, Section 11(3) 2].

l. This permit does not convey property rights or exclusive privileges [Section 1a-9 of the *Cabinet Provisions and Procedures for Issuing Title V Permits* incorporated by reference in 401 KAR 52:020, Section 26].

m. Issuance of this permit does not relieve the permittee from the responsibility of obtaining any other permits, licenses, or approvals required by the Cabinet or any other federal, state, or local agency.

n. Nothing in this permit shall alter or affect the authority of U.S. EPA to obtain information pursuant to Federal Statute 42 USC 7414, Inspections, monitoring, and entry [401 KAR 52:020, Section 11(3) 4.].

o. Nothing in this permit shall alter or affect the authority of U.S. EPA to impose emergency orders pursuant to Federal Statute 42 USC 7603, Emergency orders [401 KAR 52:020, Section 11(3) 1.].

SECTION G - GENERAL PROVISIONS (CONTINUED)

p. This permit consolidates the authority of any previously issued PSD, NSR, or Synthetic Minor source preconstruction permit terms and conditions for various emission units and incorporates all requirements of those existing permits into one single permit for this source.

q. Pursuant to 401 KAR 52:020, Section 11, a permit shield shall not protect the owner or operator from enforcement actions for violating an applicable requirement prior to or at the time of permit issuance. Compliance with the conditions of this permit shall be considered compliance with:
(1) Applicable requirements that are included and specifically identified in this permit; and
(2) Non-applicable requirements expressly identified in this permit.

2. Permit Expiration and Reapplication Requirements

a. This permit shall remain in effect for a fixed term of five (5) years following the original date of issue. Permit expiration shall terminate the source's right to operate unless a timely and complete renewal application has been submitted to the Division at least six (6) months prior to the expiration date of the permit. Upon a timely and complete submittal, the authorization to operate within the terms and conditions of this permit, including any permit shield, shall remain in effect beyond the expiration date, until the renewal permit is issued or denied by the Division [401 KAR 52:020, Section 12].

b. The authority to operate granted shall cease to apply if the source fails to submit additional information requested by the Division after the completeness determination has been made on any application, by whatever deadline the Division sets [401 KAR 52:020, Section 8(2)].

3. Permit Revisions

a. A minor permit revision procedure may be used for permit revisions involving the use of economic incentive, marketable permit, emission trading, and other similar approaches, to the extent that these minor permit revision procedures are explicitly provided for in the State Implementation Plan (SIP) or in applicable requirements and meet the relevant requirements of 401 KAR 52:020, Section 14(2).

b. This permit is not transferable by the permittee. Future owners and operators shall obtain a new permit from the Division for Air Quality. The new permit may be processed as an administrative amendment if no other change in this permit is necessary, and provided that a written agreement containing a specific date for transfer of permit responsibility coverage and liability between the current and new permittee has been submitted to the permitting authority within ten (10) days following the transfer.

SECTION G - GENERAL PROVISIONS (CONTINUED)

4. Construction, Start-Up, and Initial Compliance Demonstration Requirements

Pursuant to a duly submitted application the Kentucky Division for Air Quality hereby authorizes the construction of the equipment described herein, ~~for Phase 1:~~ emission units EU01, ~~EU02, EU03, EU04,~~ EU05, EU06, EU07, EU08, EU09, EU10, ~~EU11,~~ EU13, EU15, EU16, EU17, EU18, EU19, EU20, EU21, EU22, ~~EU23, EU24, EU26, EU27, EU28, EU29, EU30, EU31,~~ EU33, EU34, EU35A, EU35B, EU36, ~~EU37, EU38,~~ EU39, EU40, EU41, EU42, EU43, EU44, EU45, EU46, EU47, ~~EU48,~~ EU50, EU51, EU52, EU53, ~~EU54, EU55, EU56,~~ EU57, ~~EU58,~~ EU59, EU60, EU61, EU62, EU63, EU64, EU65, EU66, EU67, EU68, EU69, EU71, EU72, EU73, EU74, EU75, ~~and~~ EU76; EU77, EU78, EU79, EU80, EU81, and EU82. ~~for Phase 2: EU06, EU09, EU10, EU12, EU14, EU16, EU32, EU34, EU35B, EU41, EU42, EU46, EU47, EU49, EU51, EU62, EU65, EU70,~~

~~and EU74~~ in accordance with the terms and conditions of permit (V-16-022).

Formatted: Right: 0.48", Space Before: 4.5 pt

a. Construction of any process and/or air pollution control equipment authorized by this permit shall be conducted and completed only in compliance with the conditions of this permit.

b. Within thirty (30) days following commencement of construction and within fifteen (15) days following start-up and attainment of the maximum production rate specified in the permit application, or within fifteen (15) days following the issuance date of this permit, whichever is later, the permittee shall furnish to the Regional Office listed on the front of this permit in writing, with a copy to the Field Office Branch of the Frankfort Central Office, notification of the following:
   (1) The date when construction commenced.
   (2) The date of start-up of the affected facilities listed in this permit.
   (3) The date when the maximum production rate specified in the permit application was achieved.

c. Pursuant to 401 KAR 52:020, Section 3(2), unless construction ~~for Phase 1~~ is commenced within eighteen (18) months after the permit is issued o~~r within eighteen (18) months after March 1, 2019 for Phase 2,~~ or begins but is discontinued for a period of eighteen (18) months or is not completed within a reasonable timeframe then the construction and operating authority granted by this permit for those affected facilities for which construction was not completed shall immediately become invalid. Upon written request, the Cabinet may extend these time periods if the source shows good cause.

d. Pursuant to 401 KAR 50:055, Section 2(1)(a), an owner or operator of any affected facility subject to any standard within the administrative regulations of the Division for Air Quality shall demonstrate compliance with the applicable standard(s) within sixty (60) days after achieving the maximum production rate at which the affected facility will be operated, but not later than 180 days after initial start-up of such facility. Pursuant to 401 KAR 52:020, Section 3(3)(c), sources that have not demonstrated compliance within the timeframes prescribed in 401 KAR 50:055, Section 2(1)(a), shall operate the affected facility only for purposes of demonstrating compliance unless authorized under an approved compliance plan or an order of the cabinet.

e. This permit shall allow time for the initial start-up, operation, and compliance demonstration of the affected facilities listed herein. However, within sixty (60) days

SECTION G - GENERAL PROVISIONS (CONTINUED)

after achieving the maximum production rate at which the affected facilities will be operated but not later than 180 days after initial start-up of such facilities, the permittee shall conduct a performance demonstration on the affected facilities in accordance with 401 KAR 50:055, General compliance requirements. Testing must also be conducted in accordance with General Provisions G.5 of this permit.

f. Terms and conditions in this permit established pursuant to the construction authority of 401 KAR 51:017 or 401 KAR 51:052 shall not expire.

~~g. For those units constructed as a part of Phase 2, BACT shall be reassessed 18 months prior to commencement of construction of any Phase 2 unit and the analysis and conclusions shall be submitted to the Division for approval. [401 KAR 51:017, Section 8(4)]~~

~~h. For those units constructed as a part of Phase 2, the permittee shall re-evaluate the units for applicability of any new state or federal requirements 180 days prior to construction of any Phase 2 units and the analysis and conclusions shall be submitted to the Division for approval.~~

5. Testing Requirements

a. Pursuant to 401 KAR 50:045, Section 2, a source required to conduct a performance test shall submit a completed Compliance Test Protocol form, DEP form 6028, or a test protocol a source has developed for submission to other regulatory agencies, in a format approved by the cabinet, to the Division's Frankfort Central Office a minimum of sixty (60) days prior to the scheduled test date. Pursuant to 401 KAR 50:045, Section 7, the Division shall be notified of the actual test date at least thirty (30) days prior to the test.

b. Pursuant to 401 KAR 50:045, Section 5, in order to demonstrate that a source is capable of complying with a standard at all times, any required performance test shall be conducted under normal conditions that are representative of the source's operations and create the highest rate of emissions. If [When] the maximum production rate represents a source's highest emissions rate and a performance test is conducted at less than the maximum production rate, a source shall be limited to a production rate of no greater than 110 percent of the average production rate during the performance tests. If and when the facility is capable of operation at the rate specified in the application, the source may retest to demonstrate compliance at the new production rate. The Division for Air Quality may waive these requirements on a case-by-case basis if the source demonstrates to the Division's satisfaction that the source is in compliance with all applicable requirements.

c. Results of performance test(s) required by the permit shall be submitted to the Division by the source or its representative within forty-five days or sooner if required by an applicable standard, after the completion of the fieldwork.

SECTION G - GENERAL PROVISIONS (CONTINUED)

6. Acid Rain Program Requirements

   a. If an applicable requirement of Federal Statute 42 USC 7401 through 7671q (the Clean Air Act) is more stringent than an applicable requirement promulgated pursuant to Federal Statute 42 USC 7651 through 7651o (Title IV of the Act), both provisions shall apply, and both shall be state and federally enforceable.

   b. The permittee shall comply with all applicable requirements and conditions of the Acid Rain Permit and the Phase II permit application (including the Phase II NOx compliance plan and averaging plan, if applicable) incorporated into the Title V permit issued for this source. The source shall also comply with all requirements of any revised or future acid rain permit(s) issued to this source.

7. Emergency Provisions

   a. Pursuant to 401 KAR 52:020, Section 24(1), an emergency shall constitute an affirmative defense to an action brought for the noncompliance with the technology-based emission limitations if the permittee demonstrates through properly signed contemporaneous operating logs or relevant evidence that:
      (1) An emergency occurred and the permittee can identify the cause of the emergency;
      (2) The permitted facility was at the time being properly operated;
      (3) During an emergency, the permittee took all reasonable steps to minimize levels of emissions that exceeded the emissions standards or other requirements in the permit; and
      (4) Pursuant to 401 KAR 52:020, 401 KAR 50:055, and KRS 224.1-400, the permittee notified the Division as promptly as possible and submitted written notice of the emergency to the Division when emission limitations were exceeded due to an emergency. The notice shall include a description of the emergency, steps taken to mitigate emissions, and corrective actions taken.
      (5) This requirement does not relieve the source of other local, state or federal notification requirements.

   b. Emergency conditions listed in General Condition G.7.a above are in addition to any emergency or upset provision(s) contained in an applicable requirement [401 KAR 52:020, Section 24(3)].

   c. In an enforcement proceeding, the permittee seeking to establish the occurrence of an emergency shall have the burden of proof [401 KAR 52:020, Section 24(2)].

8. Ozone Depleting Substances

   a. The permittee shall comply with the standards for recycling and emissions reduction pursuant to 40 CFR 82, Subpart F, except as provided for Motor Vehicle Air Conditioners (MVACs) in Subpart B:
      (1) Persons opening appliances for maintenance, service, repair, or disposal shall comply with the required practices contained in 40 CFR 82.156.

SECTION G - GENERAL PROVISIONS (CONTINUED)

(2) Equipment used during the maintenance, service, repair, or disposal of appliances shall comply with the standards for recycling and recovery equipment contained in 40 CFR 82.158.
(3) Persons performing maintenance, service, repair, or disposal of appliances shall be certified by an approved technician certification program pursuant to 40 CFR 82.161.
(4) Persons disposing of small appliances, MVACs, and MVAC-like appliances (as defined at 40 CFR 82.152) shall comply with the recordkeeping requirements pursuant to 40 CFR 82.166
(5) Persons owning commercial or industrial process refrigeration equipment shall comply with the leak repair requirements pursuant to 40 CFR 82.156.
(6) Owners/operators of appliances normally containing 50 or more pounds of refrigerant shall keep records of refrigerant purchased and added to such appliances pursuant to 40 CFR 82.166.

b. If the permittee performs service on motor (fleet) vehicle air conditioners containing ozone-depleting substances, the source shall comply with all applicable requirements as specified in 40 CFR 82, Subpart B, *Servicing of Motor Vehicle Air Conditioners*.

9. Risk Management Provisions

a. The permittee shall comply with all applicable requirements of 401 KAR Chapter 68, Chemical Accident Prevention, which incorporates by reference 40 CFR Part 68, Risk Management Plan provisions. If required, the permittee shall comply with the Risk Management Program and submit a Risk Management Plan to:

RMP Reporting Center
P.O. Box 10162
Fairfax, VA 22038

b. If requested, submit additional relevant information to the Division or the U.S. EPA.

SECTION H - ALTERNATE OPERATING SCENARIOS

The alternate operating scenarios set forth below have been approved by the Division based on information supplied with the application and during the application review process. The terms and conditions of each alternate operating scenario have been developed to ensure compliance with the applicable regulations. The permittee, when making a change from one operating scenario to another, shall record contemporaneously in a log at the permitted facility a record of the scenario under which the facility is operating. The permit shield, as provided in Section G shall extend to each alternate operating scenario set forth in this Section. All conditions not specified under an alternate operating scenario shall remain unchanged from their permit values or requirements.

Commented [BEF55]: Section H can be removed in its entirety as Phase II is complete.

ALTERNATE OPERATING SCENARIO 1

Commented [BEF56]: This Alternate Scenario is based on availability of equipment during the construction phases. We have not installed EU70 and have no plans to install it.

During Phase 1 construction, the facility is exempted from 401 KAR 59:225 based on Section 6(3). Prior to starting operation in Phase 2 the facility must find an alternative paint thinner which will contain less VOC (or contain an exempt VOC compound) which at that time will ensure that the coating at the applicators will meet the requirements in 401 KAR 59:225, Section 6(1)(b): Less than 0.42 kg/l of coating (three and five-tenths (3.5) lb/gal) or the facility will comply with the requirements of 401 KAR 59:225, Section 3.

Emission Group 06 – Coating (Phase 1)

Emission Unit 68 (EU68) **Paint Booth #1**
Description:
Model: Sturm Maschinenbau ZS16
Estimated Start of Construction: August 2016
Maximum Capacity: 28.9 lb post-induction coating/hr
Controls: Paint Booth Filter (CU14)

Emission Unit 69 (EU69) **Paint Booth #2**
Description:
Model: Sturm Maschinenbau ZS16
Estimated Start of Construction: August 2016
Maximum Capacity: 28.9 lb post-induction coating/hr
Controls: Paint Booth Filter (CU15)

Emission Unit 71 (EU71) **Paint Booth #4**
Description:
Model: Sturm Maschinenbau ZS16
Estimated Start of Construction: August 2016
Maximum Capacity: 2.38 lb pre-induction coating/hr
Controls: Paint Booth Filter (CU17)

Description: Three (3) paint booths that apply coatings to finished parts. EU 68 and 69 apply a zinc paint to each part and EU71 applies both a zinc paint and a zinc solution. Each of these paint booths are equipped with electrostatic spray nozzles that achieve at least 70% transfer efficiency.

APPLICABLE REGULATIONS:
401 KAR 51:017, Prevention of significant deterioration of air quality.
401 KAR 59:010, New process operations.

SECTION H - ALTERNATE OPERATING SCENARIOS (CONTINUED)

NON-APPLICABLE REGULATIONS:

401 KAR 59:225, New miscellaneous metal parts and products surface coating operations, exempt during Phase 1 since the total potential VOC emissions from all affected facilities constructed in Phase 1 are less than 20 tons per year.

STATE-ORIGIN REQUIREMENTS:

401 KAR 63:020, Potentially hazardous matter or toxic substances, applicable with respect to each affected facility which emits or may emit Xylene, Methanol, or Zinc.

1. **Operating Limitations:**
   a. During Phase 1, the permittee shall not operate EU70.

   b. The permittee shall limit the throughput through EU68 and EU69 to a combined 92.6 tons/yr of post-induction coating on a rolling 12-month basis. [401 KAR 51:017]

   c. The permittee shall limit the throughput through EU71 to 15.5 tons/yr of pre-induction coating on a rolling 12-month basis. [401 KAR 51:017]

   d. The permittee shall limit thinner usage to a combined 4.6 tons/yr of thinner on a rolling 12-month basis. [401 KAR 51:017]

   e. Refer to **Section B**.

2. **Emission Limitations:**
   a. During Phase 1, the permittee shall not allow the combined total VOC emissions from EU68, EU69, and EU71 to exceed twenty (20) tons per year, including mixing, storage, application, drying, clean up, leaks, spills, disposal, processing, and handling. [401 KAR 59:225, Section (6)(3)]

   b. For EU68 and EU69, the permittee shall not cause or contribute to combined total emissions of PM, PM_{10}, and $PM_{2.5}$ that, on a rolling 12-month basis, equal or exceed 0.242 tons of PM, PM_{10}, or $PM_{2.5}$ per year. [401 KAR 51:017]

   c. For EU71, the permittee shall not cause or contribute to total emissions of PM, PM_{10}, and $PM_{2.5}$ that, on a rolling 12-month basis, equal or exceed 0.016 tons of PM, PM_{10}, or $PM_{2.5}$ per year. [401 KAR 51:017]

   d. For EU68 and EU69, the permittee shall not cause or contribute to combined total emissions of VOC (including contributions from thinner usage) that, on a rolling 12- month basis, equal or exceed 14.8 tons of VOC per year. [401 KAR 51:017]

   e. EU71, the permittee shall not cause or contribute to total emissions of VOC that (including contributions from thinner usage), on a rolling 12-month basis, equal or exceed 1.94 tons of VOC per year. [401 KAR 51:017]

   f. Refer to **Section B** and **Section D**.

SECTION H - ALTERNATE OPERATING SCENARIOS (CONTINUED)

ALTERNATE OPERATING SCENARIO 2

Commented [BEF57]: This Alternate Scenario can be deleted in its entirety. Baghouse CU08 has been constructed and Emission Units routed to it as described in Section B

In the initial first couple years of Phase 1 production the facility will have intermittent production with a small fraction of the capacity of the total permitted throughput of the facility. Due to the very small process exhaust requirements and intermittent operation, all baghouses with their large design air flow rates cannot be operated at the lower production rates. Subsequently several of the production operations that will be vented to a dedicated baghouse in Phase 2 will initially be ducted to another baghouse during Phase 1. Specifically, the Pouring, Cooling, Shakeout (PCS) Baghouse CU08 will not be constructed until Phase 2. When production demand is anticipated to increase and become continuous in Phase 2 of the project, Baghouse CU08 will be constructed and all process will be ducted as indicated in the original permit application and Section B of the permit (V-16-022 R1)

Temporary Phase 1 process control device routing compared to the Phase 2 design specified above:
- PCS operation emissions previously identified to have been routed and controlled by CU08, will be temporarily routed and controlled by CU01 during Phase 1 operation.
- Core Shop emissions previously identified to have been routed and controlled by CU08, will be temporarily routed and controlled by CU01 during Phase 1 operation.

The permittee may also utilize this alternate operating scenario in the event of a shut down or malfunction of CU08 after Phase 2 is complete.

Foundry Operations

Emission Unit	Description	BACT Control Device	Maximum Hourly Capacity	PSD Operating Limitations	Maximum Burner Capacity	Estimated Start of Construction
Emission Group 02 – Sand Plant						
EU33	Mold Stamping #1	Baghouse (CU01)	99.0 ton green sand/hr, each	358,380 ton green sand/yr	N/A	August 2016
EU34	Mold Stamping #2			358,380 ton green sand/yr	N/A	March 2019
EU36	Sand Classifier		3.70 ton core sand/hr, each	13,380 ton core sand/yr	N/A	August 2016
EU37	Core Silica Sand Bin			13,380 ton core sand/yr	N/A	August 2016
EU38	Core Silica Sand Weigh Hopper			13,380 ton core sand/yr	N/A	August 2016
EU43	Core Removal		3.70 ton core sand/hr	13,380 ton core sand/yr	N/A	August 2016
EU44	Dryer #1		32 lb coating/hr; 34 lb binder/hr, each	34.35 MMscf/yr; 58.3 ton coating/yr; 60.2 ton binder/yr	4.0 MMBtu/hr	August 2016

SECTION H - ALTERNATE OPERATING SCENARIOS (CONTINUED)

Emission Unit	Description	BACT Control Device	Maximum Hourly Capacity	PSD Operating Limitations	Maximum Burner Capacity	Estimated Start of Construction
EU45	Dryer #2	Baghouse (CU01)	32 lb coating/hr; 34 lb binder/hr, each	34.35 MMscf/yr; 58.3 ton coating/yr; 60.2 ton binder/yr	4.0 MMBtu/hr	August 2016
EU46	Dryer #3			34.35 MMscf/yr; 58.3 ton coating/yr; 60.2 ton binder/yr	4.0 MMBtu/hr	March 2019
EU47	Dryer #4			34.35 MMscf/yr; 58.3 ton coating/yr; 60.2 ton binder/yr	4.0 MMBtu/hr	March 2019
Emission Group 03 – Casting & Molding						
EU48	Mold Assembly #1	Baghouse (CU01)	100.8 ton total used sand/hr, each	365,070 ton total used sand/yr	N/A	August 2016
EU49	Mold Assembly #2			365,070 ton total used sand/yr	N/A	March 2019
EU50	Pouring #1		12.7 ton gray iron/hr, each	45,793 ton gray iron/yr	N/A	August 2016
EU51	Pouring #2			45,793 ton gray iron/yr	N/A	March 2019
EU52	Cooling Tunnel		25.3 ton gray iron/hr, each	91,586 ton gray iron/yr & 8.59 MMscf/yr	1 MMBtu/hr	August 2016
EU59	Forced Air Cooler			91,586 ton gray iron/yr	N/A	August 2016

Description: The processes listed above are considered to meet the definition of Foundry Operations, as defined in 40 CFR 63.10906, which means all process equipment and practices used to produce metal castings for shipment, including: Mold or core making and coating; scrap handling and preheating; metal melting and inoculation; pouring, cooling, and shakeout; shot blasting, grinding, and other metal finishing operations; and sand handling.

APPLICABLE REGULATIONS:
401 KAR 51:017, Prevention of significant deterioration of air quality.
401 KAR 59:010, New process operations.
401 KAR 63:002, Section 2(4)(bbbbb) implementing **40 CFR 63, Subpart ZZZZZ,** *National Emission Standards for Hazardous Air Pollutants for Iron and Steel Foundries Area Sources.*

1. **Operating Limitations:**
   Refer to **Section B**.

2. **Emission Limitations:**
   a. The permittee shall not allow the emissions exiting the following control device to exceed the following: [401 KAR 51:017]

SECTION H - ALTERNATE OPERATING SCENARIOS (CONTINUED)

Control Device (Stack)	Emission Units Controlled	Type of Control and Pollutants Controlled	BACT for PM	BACT for PM_{10}	BACT for $PM_{2.5}$
CU01 (ST02)	EU02, EU04, EU07, EU08, EU09, EU10, EU11, EU12, EU15, EU16, EU33, EU34, EU36, EU37, EU38, EU43, EU44, EU45, EU46, EU47, EU48, EU49, EU50, EU51, EU52, EU59	Baghouse (PM, PM_{10}, $PM_{2.5}$)	0.0010 gr/dscf; 1.42 lb/hr; 6.20 ton/yr	0.0010 gr/dscf; 1.42 lb/hr; 6.20 ton/yr	0.00060 gr/dscf; 0.850 lb/hr; 3.72 ton/yr

Compliance Demonstration:
The permittee shall conduct performance testing on CU01, while operating in this alternate operating scenario to demonstrate initial compliance with the BACT limits listed above. The testing shall be performed according to the requirements of 401 KAR 50:055, and repeated every 5 years. The permittee shall use 40 CFR 60, Appendix A, Method 5 for PM, 40 CFR 51, Appendix M, Method 201A/202 for PM_{10} and $PM_{2.5}$. This testing shall also determine emission factors for each group of units in pounds per MMscf of natural gas used, ton of metal poured, number of parts produced, or other appropriate unifying units as approved by the Division, for use in the equation below. This testing shall be repeated when the remaining units constructed during Phase 2 within the group are completed and operational.

Continuous compliance will be demonstrated by use of the bag leak detection system required in **SECTION E,** meeting the throughput limits for each process in **SECTION B** and **SECTION H**, and calculating the lb/hr and rolling 12-month ton/yr emissions from each group of units, using the following equations:

$$\frac{P_i * EF}{h_i} = H_i$$

And:

$$\sum_{i=1}^{12} H_i * \frac{h_i}{2000} = Y$$

Where:
i = Month;

P_i = Monthly throughput for month i in the group of emission units (CU01, CU06, CU08, CU11, and CU13) in units/month;
EF = The corresponding emission factor for PM, PM_{10}, $PM_{2.5}$, CO or VOC as determined using a representative performance test conducted according to the requirements of 401 KAR 50:045, within the last five (5) years, in lb/unit;
h = the total number of hours operated during month i;
H_i = total PM, PM_{10}, $PM_{2.5}$, CO or VOC emissions in lb/hr.
Y = Total rolling 12-month yearly emissions in tons/year.
Note: This calculation shall include all emission units that emit PM, PM_{10}, or $PM_{2.5}$ within the group.

b. Refer to **Section B** and **Section D**.

Section 1
Project Introduction

1.1 Document Summary

This document provides an application to correct Air Quality Permit V-16-022 R1 (Air Permit) issued on November 25, 2017, to Fritz Winter North America LP (FWNA). The necessary corrections were identified as a result of required performance testing; air permit required monitoring and recordkeeping and a detailed review of the above identified air permit.

To reduce the resources required to review and process this application, the 2017 and the 2022 applications have been used as base documents for any necessary text changes. During review of historical project information, several Kentucky Division for Air Quality (DAQ) questions, issues and concerns regarding previous applications were identified and addressed within this document. To conserve as much of the original application as possible, Figures and Tables have been consolidated into appendices.

Additional project background information is provided in this section.

1.2 Introduction

As authorized by the Air Permit, FWNA constructed and operates a gray iron foundry and machining operation to produce automotive parts, predominantly brake rotors. The facility is located in the Wilkey North Industrial Park located in Franklin, Simpson County, Kentucky. The facility is located approximately five miles north of Franklin and 13 miles south of BowlingGreen along State Route 31W.

The facility is listed under the Standard Industrial Classification (SIC) code of 3714 - Motor Vehicle Parts and Accessories. The Air Permit restricts the maximum production capacity of the foundry to 91,586 tons of molten gray iron poured per year. T**his application requests a reduction in the maximum capacity to 80,000 tons of gray iron poured per rolling 12-month summation.**

1.3 Project Background

As a result of Air Permit required initial performance testing, it was determined that certain established emission limitations were not met. This section identifies the units and pollutants where emission limitations were exceeded and provides a brief analysis of likely causes.

1.3.1 Applicable Permit Limits

In addition to and in concert with other applicable sections, Section B (Foundry Operations), Section B (Coating Operations), Section D.5, Section D.7, Section G.4.e, Section G.4.h, Section G.5. and Section H.2. of Air Quality Permit V-16-022 R1 issued on November 25, 2017, includes provisions to conduct performance (emission) testing to verify compliance with permit established emission limitations.

During 2018 and prior to the installation of Control Device CU08 with Stack ST09 (identified in a format of Control Device ID/Stack ID, e.g., CU08/ST09 throughout this document), FWNA was to

comply with Alternative Operating Scenario #2 provided for in Section H of the referenced air permit.

Alternative Operating Scenario #2 allowed the foundry to temporarily exhaust emission units EU33, EU34, EU36, EU37, EU38, EU43, EU44, EU45, EU46, EU47, EU48, EU49, EU50, EU51, EU52, EU59 to Baghouse CU01 (CU01/ST02) prior to the installation of CU08/ST09. Operating per Alternative Operating Scenario 2 is identified in the Air Permit as Phase 1 per the note at the bottom of the emission unit table provided in Section B (Foundry Operations).

When FWNA is conducting production activities under Alternative Operating Scenario #2, Air Permit Section H.2 (i.e., Phase 1) establishes PM, PM_{10} and $PM_{2.5}$ emission limitations for CU01/ST02 as shown in Table 1-1 provided in Appendix A (all report tables may be found in Appendix A).

Air Permit Section D.5 provides emission limitations for CU06/ST07 and CU11/ST12. These emission limits are effective when operating under Phase 1 as well as once Baghouse CU08 is installed (i.e., Phase 2).

Section D.5 also identifies PM, PM_{10} and $PM_{2.5}$ emission limitations for CU01/ST02 and CU08/ST09 during Phase 2 (once Baghouse CU08/ST09 has been installed and the exhaust ducts from emission unit IDs EU33, EU34, EU36, EU37, EU38, EU43, EU44, EU45, EU46, EU47, EU48, EU49, EU50, EU51, EU52, EU59 are moved from CU01/ST02 to CU08/ST09). [It is beneficial to note the facility continues to operate the existing coating operations under Section H. Alternative Operating Scenario #1].

Table 1-2 provides those Section D.5 identified PM, PM_{10} and $PM_{2.5}$ emission limitations during Phase 2 for CU01/ST02 and CU08/ST09 as well as PM, PM_{10} and $PM_{2.5}$ emission limitations during both Phase 1 and Phase 2 for CU06/ST07 and CU11/ST12.

Comparing Table 1-1 and 1-2 it is worth noting that CU01/ST02 PM, PM_{10} and $PM_{2.5}$ emission limitations did not change to reflect the movement of a number of particulate matter generating sources from CU01/ST02 to CU08/ST09 as the facility transitioned from Phase 1 to Phase 2 operations. Put another way, prior to transitioning to CU08/ST09, a number of units with condensable particulate matter emissions were ducted to CU01/ST02. The CU01/ST02 emission limitations were not altered to reflect the possibility of the increased condensable emissions associated with these units during Phase 1 operations.

Table 1-3 provides the volatile organic compound (VOC) and carbon monoxide (CO) emission limitations for CU1/ST02, CU07/ST08 (VOC only) and CU08/ST09. These emission limitations are effective during both Phase 1 and Phase 2. **Similar to the PM, PM_{10} and $PM_{2.5}$ issued identified above, CU08/ST09 has VOC and CO emissions rates that were not addressed within the emission limitations for CU01/ST02 when operating under Phase 1.**

Finally, Air Permit Section B.3.h. identifies performance test requirements for the Shakeout Conveyor (EU53) to determine compliance with VOC and CO BACT emission limits identified in Section B.2.e. and f. These emission limits are identified in Table 1-4 and apply during both Phase 1 and 2.

1.3.2 Initial Performance Test Results (CU01/ST02) – Phase 1

During Phase 1 the initial performance testing was conducted for the Melt Shop Baghouse (CU01/ST02) and Sand System Baghouse (CU06/ST07) in November 2018 and December 2018. Results of those tests are provided in Table 1-5 and Table 1-6 for CU01/ST02 and CU06/ST07, respectively.

The CU06/ST07 results provided in Table 1-6 assumed the only source of VOC and/or CO emissions were from the Shakeout Conveyor (EU53), and therefore any VOC and CO emissions determined at the stack were assigned to the Shakeout Conveyor (EU53).

The performance test of the CU01/ST02 yielded results that exceeded the permitted emission rates for PM_{10}, $PM_{2.5}$, VOC, and CO. **Again, as identified above, CU01/ST02 emission limitations in the Air Permit were not adjusted to reflect the emissions from the units temporarily ducted to CU01/ST02 during Phased 1 operations**.

The performance test of CU06/ST07 determined PM_{10} and $PM_{2.5}$ emissions exceeded applicable emission limits identified in Table 1-6 or correspondingly identified in Table 1-2.

As stated above, since CU06/ST07 was assumed to have no other sources of VOC and CO, it was inferred that those emission rates determined from testing CU06/ST07 were from the Shakeout Conveyor (EU53) and therefore indicated the Shakeout Conveyor exceeded the allowable VOC emission rate provided in Table 1-4.

1.3.3 Performance Test Results – Phase 2

Section D.5 and D.6 of the Air Permit includes provisions to repeat performance testing following completion of Phase 2 construction activities. The Phase 2 construction activities included installation of Baghouse CU08/Stack ST09 and moving exhaust ducts for several emission units from CU01/ST02 to CU08/ST09.

In October 2019, the initial performance testing of CU08/ST09 was completed and showed compliance with Phase 2 emission limitations for PM, PM_{10}, $PM_{2.5}$, VOC, and CO.

In March 2020, performance testing was conducted for CU01/ST02 and CU06/ST07. The resulting pollutants in excess of emission limitations were $PM_{2.5}$, VOC, and CO for CU01/ST02 and $PM_{2.5}$ and VOC from CU06/ST07 and EU53, respectively. Note $PM_{2.5}$ emissions from CU01/ST02 and CU06/ST02 were only slightly above permitted limitations as was the VOC emissions from EU53.

A summary of the performance test results are provided and compared to the corresponding emission limits in Table 1-7 and Table 1-8 for CU01/ST02 and CU06, respectively.

1.3.4 Performance Test Results – June 2024

FWNA's 2022 air permit modification application remained pending when the Department of Air Quality (DAQ) requested additional emissions testing. This testing was completed in June 2024, with results compared against existing permit limits in Tables 1-9 through 1-11. A summary of the test results are provided below.

CU01/ST02: The June 2024 testing confirmed earlier findings from Section 1.3.2 and 1.3.3, showing that volatile organic compound (VOC) and carbon monoxide (CO) emissions surpassed the permitted hourly limits. Particulate emissions of all types stayed within acceptable ranges. However, the facility operated at reduced capacity during testing, which likely lowered pollutant inlet concentrations and may have understated actual particulate emission rates.

CU06/ST07: Testing revealed VOC emission limits continuing to exceed the permitted hourly threshold. Similar to other units, the decreased production during the test period possibly resulted in lower incoming pollutant levels, potentially skewing particulate matter and carbon monoxide measurements.

CU08/ST09: This stack met all permit requirements for particulate concentrations and hourly emission thresholds during testing. Nevertheless, the reduced operational intensity during the test period likely influenced these measurements. To provide a more accurate assessment, VOC and CO emission rates were normalized to metal throughput. When evaluated on a metal throughput basis, the results from the June 2024 performance test exceed the implied VOC and CO emission limits specified in the Air Permit.

Conclusion: While some test results appeared acceptable under reduced production conditions, the normalized data suggests potential compliance challenges during normal operations.

1.3.5 Summary of Additional Performance Testing and Permit Implications

In addition to the above described test results, performance testing in 2018, 2019, 2020 and/or 2024 was conducted on stacks associated with the Acid Scrubber CU07 (Stack ST08), Paint Line 3 (CU14/ST15A), Paint Line 2 (CU15/ST15B), and Paint Line 1 (CU17/ST16). The findings of those tests and the permit application implications are discussed below:

Acid Scrubber (CU07/ST08)

- The November 2018 test yielded unexpected carbon monoxide (CO) emissions despite no sources of the CO emissions and no underlying permitted emission limitations. This is believed to be an anomaly and no changes to the permit application are proposed.
- The same above test showed VOC emissions at 84% of the allowable limit, even though the production rate was only 13% of the permitted capacity suggesting that higher emissions may occur at capacity.
- The June 2024 yielded VOC emissions at approximately 225% of the permitted hourly emissions limit despite a significantly reduced production rate. This again indicates a need to reassess the VOC emission limits.

Fettling Baghouse (CU11/ST12)

- Performance testing in November 2018 and June 2024 confirmed compliance with the current emission limitations.

Paint Line Stacks (CU14/ST15A, CU15/ST15B, CU16/ST16)

- June 2024 performance testing of Paint Lines 3, 2 and 1 identified particulate and VOC emissions that may exceed annual permit limits.
- Particulate exceedances are attributed to underestimating outlet grain loading values in the original application as well as the presence of condensable particulate matter.
- Testing of Paint Lines 3 and 2 indicates the coating capacity may be underestimated along with the corresponding VOC emission rates.

- The above will be addressed in the permit application revision.

1.3.6 Performance Test Results Analysis

The following provides a discussion of the likely causes of the excess emissions.

CU01 PM_{10}/$PM_{2.5}$ and CU06 $PM_{2.5}$ Emission Limit Exceedances

From reviewing the above PM results, the minimal PM outlet loading indicates the baghouses are performing extremely well at removing filterable PM. The results of the performance test show the measured filterable emission rates meet the current permit PM BACT emission limitations. Potential causes of the emissions limit exceedance include:

- The exceedances of the PM_{10} and $PM_{2.5}$ emission limitation exceedances is the results of the prior permit application's failure to address condensable particulate emissions that can occur during foundry melting, pouring, cooling and/or shakeout operations. No foundry identified in the RACT/BACT/LAER Clearinghouse (RBLC) have PM_{10} and $PM_{2.5}$ emission rates, including condensable, at these low emission rates.
- As identified above, another reason the CU01/ST02 PM_{10} and $PM_{2.5}$ emission limitations were exceeded was a result of the additional emission units and their associated condensable particulate emissions venting to CU01/ST02 during Phase 1 while no accommodation was made in the Air Permit.

To address this issue a revised BACT evaluation will be conducted to determine appropriate PM_{10} and $PM_{2.5}$ emission rates for these operations.

CU01/ST02, CU06/ST07, and CU08/ST09 VOC/CO Emission Limit Exceedance

There are several factors that likely led to the excess VOC and CO emission limitations from these stacks and the corresponding emission units. Those factors include the following:

- As identified above regarding the Phase 1 PM_{10} and $PM_{2.5}$ emission limitations, the Air Permit did not consider VOC and CO emission rates from the additional emission units vented to CU01 during Phase 1 when establishing the Air Permit limits.
- Second, VOC and CO emissions vary across pouring, cooling and shakeout based on a number of factors (e.g., cooling time). When assessing compliance with VOC and CO emission limitations it is important to aggregate the performance test results across the applicable stacks and compare those results against a grouped emissions limit for the selected units. The Air Permit did not provide for this allowance.
- Third, it does not appear the VOC Shakeout BACT determination accurately reflects the expected VOC emission rate. The prior BACT identified Waupaca Foundry as having a VOC emission limit of 0.1 lb./ton of metal. It is known Waupaca has not been able to demonstrate compliance with that emission limitation.
- Finally, we believe secondary capture of some emissions is occurring and being vented to these stacks resulting in greater emissions of VOC and CO.

CU07/ST08 VOC Emission Limit Exceedances

The emission rates in excess of the VOC hourly emissions limitation resulted in a review of the existing air pollution control device as well as correspondence with the resin supplier to develop

improved emission estimates. The revised VOC emission rates are included in this air permit application.

CU14/ST15A, CU15/ST15b and CU17/ST16 PM and VOC Emission Limits
The performance testing conducted on the stacks serving Paint Line 3 (EU68), Paint Line 2 (EU69) and Paint Line 1 (EU71) resulted in particulate and VOC emission rates that may exceed annual emission limitations. Outlet grain loading from the fabric filters have been evaluated as well as the coating usage rates for each of the three paint lines to more accurately address particulate emissions.

To address the above issues a revised BACT evaluation has been conducted to determine appropriate VOC and CO emission rates for these operations.

1.4 Revisions to Previous Permit Applications

Given the results of the above performance tests, the knowledge of other available foundry emissions information and the ongoing Air Permit Monitoring and Recordkeeping, this revised permit application has been prepared to address the above emission limitation exceedances. These changes are summarized in Tables 1-12 through 1-14 by comparing the expected revised emission rates and BACT to the same values provided in the current Air Permit.

Important aspects of each table can be summarized as follows:

- The proposed BACT values provided in Table 1-13 result in an annual decrease in potential emissions of PM, PM_{10} and $PM_{2.5}$ emissions as shown in Table 1-12.
- Table 1-14 shows an overall potential VOC and CO increase of approximately 144 and 37 tons, respectively and is the result of revisions made mainly to the CU08/ST09 VOC emission rates to incorporate increase emissions associated with organics in the green sand mold and chemically-bonded core package.

In addition to the changes identified in Tables 1-13 and 1-14, the revised application includes requests for the following changes:

- Change hourly and annual equipment capacity to rates identified in the emission calculations and application forms to reflect the below identified equipment that will not be installed.
- This application requests a reduction in the maximum capacity to 80,000 tons of gray iron poured per rolling 12-month summation.
- Remove several emission units identified in the initial and 2022 permit application that will not be installed including Scrap Drying (EU03), Scrap Cleaning (EU04), Holding Furnace #1 (EU11), Holding Furnace #2 (EU12), Pouring Furnace #2 (EU16), Mold Stamping #2 (EU34), PUCB Core Machine #3 (EU41), PUCB Core Machine #4 (EU42), Core Dryer #3 (EU46), Core Dryer #4 (EU37), Mold Assembly #2 (EU49), Mold Shop Baghouse Waste Dust Silo (EU58), Steel Shot Blasting #2 (EU62), Paint Booth #3 (EU70), Gasoline Storage Tank (EU75), Core Wash Station #3 (EU80), and Core Wash Station #4 (EU81). See Table 2-1 as referenced in Section 2.
- Change emission unit descriptions and names. See Table 2-1 as referenced in Section 2.
- Removal of BV-01A, BV-01B, BV-02A, and BV-02B as they are no longer used.
- Increase Core Release (EU39-EU42) and Core Wash #1 and #2 (EU43, EU79) to reflect actual operational capacity;

- Remove shotblast media limit (EU61 and EU62) as the emission factor is based on tons of metal processed;
- Remove bentonite, silica, bond, and other usages not material to emission calculations and associated limits;
- Increase coremaking catalyst (EU39-EU40) usage to reflect potential usage rates;
- Add Rust Preventative (EU82) and Snag Grinding (EU77 and EU78) emission units.
- Add Rotary Sprue Cleaner and Conveyors (EU83).
- Integrate Section H, Alternative Operating Scenario 1 as it is the base permitted scenario.

1.5 NSR Applicability

The initial installation and subsequently issued permit estimated emissions above the Prevention of Significant Deterioration (PSD) major source threshold for carbon monoxide (CO). In addition, the project has significant emission rates of particulate matter (PM), PM with an aerodynamic diameter of less than 10 microns (PM_{10}), and PM with an aerodynamic diameter of less than 2.5 microns ($PM_{2.5}$). Revised emissions calculations now project that potential volatile organic compounds (VOCs) emissions will exceed the major source threshold.

1.6 Application Contents

This permit application includes: a process description (Section 2), a summary of the expected air emissions (Section 3), a regulatory analysis of the proposed project (Section 4), a Best Available Control Technology (BACT) analysis (Section 5), the required air quality modeling analysis (Section 6), and an assessment of other impacts (Section 7). The required Kentucky Division of Air Quality (DAQ) air permit application forms may be found in Appendix U.

Section 2
Process Description

2.1 Process Overview

The process of producing cast iron metal parts first involves fabricating a green sand mold and then filling it with molten iron. Once the metal cools and solidifies, the mold is broken to recover the cast metal part which then undergoes machining and final finishing. Figures are provided in Appendix B and Figure 2-1 provides a simplified process flow diagram of the overall foundry and machining process.

The mold making process occurs in two steps. First the outer part of the mold is formed by filling two halves of a reusable steel frame with green sand. Green sand consists of silica sand, bentonite, and a carbon blend, such as seacoal or other carbonaceous material.

Green sand is produced in the sand plant. Green sand raw materials are delivered to the facility by truck or rail and stored in silos. After both halves of the mold frame are filled with green sand, the green sand is compacted and stamped with the shape of the desired metal casting. Certain metal parts require portions of the casting to be hollow. To make these hollow sections, a separate core must be fabricated and placed in the green sand mold.

The core is subject to intense heat and stress and must be fabricated using silica sand bound by a two-part phenolic urethane binder. The core is coated with a water based abrasive resistant coating to provide additional protection during the pouring of molten metal. Once the core is placed into the bottom half of the green sand mold, the top half mold frame is placed on top of the bottom half frame and conveyed to the pouring (casting) area.

Molten gray iron is produced at the melt shop in electric induction furnaces where scrap iron and various alloys are weighed out according to the desired specifications and heated. Molten iron is then transferred into a transport ladle and moved to a pouring furnace. Here the molten iron is poured into the assembled mold. The iron filled mold is then conveyed to a cooling tunnel where the iron is allowed to cool and solidify. Once solidified, the mold is broken apart in a "shakeout" area and the metal frames are taken off and sent back to the mold assembly area for reuse. Mold and core sand is recovered and sent to the sand plant for reuse. Rough castings are further cooled by forced air and sent to the finishing area where they first go through a shot blasting (i.e., cleaning) process, followed by grinding, machining, and finally a protective zinc coating is applied.

The following sections describe the production process in more detail. Air emission units are identified with the letters “EU” followed by a unique number. Emission control units are identified with the letters “CU.” Emission points that vent to the atmosphere through a stack are identified by the letters “ST.”

Emission unit Identification numbers, descriptions and the requested description changes incorporated into this application are provided in Table 2-1. The table also includes units identified in the Air Permit and 2022 permit application that will not be installed.

Tables 2-2 and 2-3 identify the emission control unit and stack for each emission unit by identification number and description. These tables also provide the following information:

- Identify where emissions from a control device are captured and vented from an alternative control device stack;
- Similar to Table 2-1, identify where emission units have been combined with this application;
- Similar to Table 2-1, identify emission units, air pollution control devices and/or stacks that will not be installed.

2.2 Melt Shop

A process flow diagram of the melt shop operations is presented in Figure 2-2. Raw materials delivered to the melt shop for production of gray iron include; scrap steel or iron, various alloys, and fluxing agents. Raw materials are delivered to the facility by rail or truck and stored inside the building. FWNA receives scrap as a raw material. Scrap is managed per the pertinent requirements of the National Emission Standards for Hazardous Air Pollutants for Iron and Steel Foundries Area Sources as codified in 40 Code of Federal Regulations (CFR) Part 63 Subpart ZZZZZZ (the Foundry Area Source Rule).

The following describes the Charge Handling emission unit (EU01). Incoming scrap is stored in bins inside the building and transferred to weigh scales for processing using an overhead crane fitted with an electromagnet. Alloys and fluxes are stored in designated areas inside the building. These additives include carbon, magnesium, molybdenum, copper, chromium, vanadium, and niobium. The alloy storage area is designed with air intakes to draw in fugitive dust and duct it to the Melt Baghouse (CU01). Alloys and additives are added manually to the furnace, according to specifications and analysis.

Induction furnaces are the cleanest form of melting iron. The scrap is melted by heat generated by passing a high amperage electric current through coils surrounding the steel jacket of the furnace. The alternating current in the coil induces an internal current in the scrap metal inside the furnace that in turn produces enough heat to melt the scrap and alloys. There are a total of four induction furnaces (EU07-EU10) with a capacity to produce 10 tons per hour (tph) of molten iron each [the Pouring operation can only process 15 tph of molten metal. Prior to heating a pivoted ring hood is lowered over the top of the furnace that collects emissions generated during the melting process. Induction furnace emissions are vented to the Melt Baghouse (CU01) then is exhausted via stack ST02.

Flux added to the molten metal extracts impurities from the melt and forms a slag at the surface of the molten metal. Since clean scrap is used there is only a small number of impurities that need to be removed. The slag is removed from the surface of the molten iron by raising the hood slightly and using a long-handled scoop, manually skimming off the top of the molten metal. The slag is placed in a small portable dumpster next to the furnace. When the iron in the induction furnace meets the specific elemental analysis and consistency, the hood is raised, and the furnace is tilted so the molten iron flows into a transport ladle.

To prepare for casting, the transport ladle is conveyed (Hot Metal Transfer – EU13) to the pouring area where the molten iron is poured from the transport ladle into an electrical induction pouring furnaces (EU15).

The induction furnaces are vented to the Melt Baghouse (CU01). Emissions for Hot Metal Transfer (EU13) and Pouring Furnace #1 (EU15) are incidentally captured by local exhaust hoods and ducted to the Melt Baghouse (CU01).

Pouring Furnace #1 is equipped with a small natural gas burner designed to initially heat the vessel when first brought into service from a cold start, and to keep the pouring spout hot so the molten iron does not cool against cold refractory when being poured.

Baghouse dust collected from the Melt Baghouse is conveyed to the Melt Baghouse Waste Dust Silo (EU17). The waste dust silo is equipped with a bin vent filter (CU02). The bin vent emission point is designated as ST03.

2.3 Sand Plant

There are three basic raw materials used to make the green sand mold (EU33). These are: silica sand; bentonite, which is a clay material that acts as the glue to hold the sand in the desired shape; and a carbon source, commonly a blend of bentonite and coal dust, commonly referred to as seacoal, or some other carbonaceous material which minimizes sand sticking to the iron casting. Figure 2-3 provides a process flow diagram of the sand plant.

Raw materials for the sand plant are delivered to the facility by truck and offloaded pneumatically into dedicated storage silos (EU19-EU21). Each silo has its own bin vent filter to control particulate emissions (CU03-CU05) and their associated emission points are ST04-ST06. From the silos, materials are pneumatically transferred to day bins and then to weigh hoppers . Specific proportions of each material is placed into the green sand mixers for blending. Recycled sand from the shakeout operation is also added to the green sand mixer. Most of the recovered sand from the shakeout process is recycled back into the green sand process. This equipment operates continuously and/or semi-continuously and the emissions unit is identified as Mold Sand Handling and Preparation (EU22).

Some of the sand (approximately 5%) must be purged from the mold sand system so that the residual core sand binder decomposition byproducts do not accumulate. This waste sand is sent to the Sand Plant Waste Sand Storage Silo (EU57) where it is later shipped off site for recycling or to a landfill. Like all other silos in the foundry the waste sand storage silo has a bin vent filter (CU10) and vents to atmosphere through emission point ST11. All of the sand system day bins, weigh hoppers and mixers are ducted to the Sand Plant Baghouse (CU06) that vents to atmosphere via stack ST07 (see Tables 2-2 and 2-3).

2.4 Core Shop

To make the required voids and hollows in a brake rotor casting, a specially shaped, structurally sound, and dimensionally stable core needs to be fabricated and placed into the green sand mold before mold assembly and casting. Figure 2-4 provides the process flow diagram for the core shop.

Core silica sand is delivered to the facility by truck and pneumatically conveyed into one of two core silica sand storage silos (EU35A-EU35B). As required, core sand is pneumatically conveyed from a silo through a sand classifier that uses air to remove fine-sized particles to produce a uniform grain-sized sand feed stream. The classified sand is then pneumatically conveyed to a sand bin for temporary storage. To make the core strong enough to remain intact during the

molten iron casting process, FWNA uses the phenolic urethane cold box (PUCB), or coldbox method of core production. In the coldbox process, silica sand from the sand bin is fed to a weigh hopper before being mixed with a two-part phenolic resin in an enclosed mixer. The sand classifier, transfer of sand to sand bin and then the transfer of sand to the weigh hopper comprise the Core Sand Handling and Preparation emission unit (EU36).

The blended core sand is then sent to one of two automated core machines (EU39-EU40). After the resin and sand mixture is shaped in the core machines, an amine gas (vaporized dimethyl propylamine) is injected through the porous phenolic urethane resin/ silica sand mixture. The amine acts as a catalyst to accelerate the curing time of the phenolic urethane resin. The amine gas remains unreacted and is ducted from each core machine to a common sulfuric Acid Scrubber (CU07) and vented to the atmosphere through stack ST08. The primary purpose of scrubbing out the amine gas is for odor control. In the core machines, an oil-based release agent is applied to the core stamping patterns to allow easy separation of the cores from their pattern. This material would likely be exhausted via CU07/ST08.

The hardened cores are then coated by dipping into a water-based, pyrophyllite slurry, which provides additional abrasive protection which is applied in one of two coating units (EU43, EU79). The coated cores are then sent through an associated natural gas fired dryer (EU44-EU45), each with a heat input of 4.0 MMBtu/hr (see Figure 2-4). Emissions from the core silica sand silos, sand classifier, sand bin, weigh hopper, core removal area and the dryers are vented to the Core/Mold Baghouse (CU08) and vented to the atmosphere through stack ST09.

2.5 Mold Assembly

The top and bottom halves of the molds, cope and drag respectively, along with the core inserts are assembled in the mold-making area (EU33).

The mold assembly process starts with an outer metal frame onto which a release agent is applied before the frame is filled and compacted with green sand. The outer shape of the desired casting is then stamped into both the cope and drag of the green sand (Mold Making #1). Cores are placed into the bottom half of the molds before the top half of the mold is placed on the bottom half to form one complete sealed mold. The mold is then conveyed to the pouring furnace. Emissions generated from the mold assembly area are ducted to the Core/Mold Baghouse (CU08) which exhausts to the atmosphere through stack ST09.

2.6 Pouring, Cooling and Shakeout

The pouring, cooling, and shakeout (PCS) process is presented in the process flow diagram in Figure 2-5. The three PCS operations occur along one continuous conveyor line. At the pouring station (Pouring #1, EU50) molten iron from the pouring furnace is transferred into the assembled molds that are brought to Pouring Furnace #1 on a rail system.

The molds are designed to allow the molten iron to be poured into one fill port. Due to the extreme heat contacting the carbon in the mold and the resin in the core, CO and volatile organic compounds (VOCs) are generated. Vents throughout the mold allow hot gases produced during the pouring process to escape which typically auto-ignite. To enhance the autoignition process, natural gas mold vent pilot burners are strategically placed at the mold conveyor to ignite the vent gases that have not already ignited.

The casted molds are then conveyed through a cooling tunnel (EU52) to allow controlled cooling of the molten iron to form the required metal crystalline structure. Emissions from the pouring stations and cooling tunnel are routed to the Core/Mold Baghouse (CU08) and exhausted via stack ST09.

Once the iron castings solidify, the mold frames are opened, and the sand mold enters the shakeout conveyor (EU53) where the molds are broken, and the castings separated from the mold and core sand. Emissions from the shakeout conveyor are vented to the Sand Plant Baghouse (CU06) which is vented to the atmosphere through stack ST07.

The sand falls onto a conveyor that returns the sand to the Sand Plant. Before returning to the Sand Plant, the used mold and core sand runs through a sand screening sieve and a sand cooler where air and water are applied to obtain the desired cooling effect and moisture content. The recycled sand is then transferred to storage where it is blended again with other raw materials to make new green sand. This equipment is all part of the Mold Sand Handling and Preparation emission unit (EU22).

Due to impurities in the sand generated from heating the resin-based core sand and carbon in the green sand, some of the recycled sand must be taken out of the sand system and disposed of. Sand destined for a landfill is temporarily stored in the Sand Plant Waste Sand Silo (EU57). Emissions from the sand screen sieve, sand cooler, used sand storage is ducted to the Sand Plant Baghouse (CU06) and vented through stack ST07. Dust generated from the Waste Sand Silo (EU57) is filtered by a silo bin vent (CU10) before exhausting to the atmosphere through stack ST11.

The Shakeout Conveyor (EU53) also breaks away the sprues from the casting which are separated and sent back to the melt shop as internal scrap. The castings are conveyed to the Forced Air Cooler (EU59) before entering the finishing stage. The air used to cool the castings is a mixture of recycled air leaving the cooling tunnel and fresh makeup air. Exhaust from the Forced Air Cooler (EU59) is routed to the Core/Mold Baghouse CU08.

2.7 Finishing

The finishing process is presented in Figure 2-6. After the castings are cooled in the forced air cooler, the parts are sorted at the Sorting Conveyor (EU60) to remove any remaining sprues. Residual sand is removed from the sprue via the Rotary Sprue Cleaner (EU83) with the sand and sprue being transferred with associated conveyors (EU83). Emissions from the Sorting Conveyor are incidentally captured via the Fettling Baghouse (CU11) with emissions from the Rotary Sprue Cleaner and associated Conveyors vented to either the Core/Mold Baghouse (CU08/ST09) or the Fettling Baghouse (CU11/ST12).

Castings are sent through an abrasive steel shot blasting unit (Steel Shot Blasting #1, EU61) to remove any remaining sand and to smooth the casting surface. Parts then enter one of two grinding stations (EU64-EU65) which removes any remaining sprue or raised surface from the casting. Also, one of two snag grinders (EU77-EU78) may be used for removing metal from the castings. Steel Shot Blasting #1 and Auto-Grinding #1/#2 are ducted to the Fettling Baghouse CU11 which vents to the atmosphere through stack ST12. Dust from the Fettling Baghouse is conveyed

to the Fettling Baghouse Waste Dust Silo (EU63) whose emissions are controlled by the Fettling Baghouse Waste Dust Silo Bin Vent Filter (CU12) via stack ST13.

Snag Grinder #1 and #2 each have their own fabric filters (CU21, CU22) that vent inside the building. Any emissions from these stacks would be captured by the Fettling Baghouse (CU11) and vented through stack ST12.

Finished castings are sent to short-term storage to allow the gray iron to fully crystallize before being sent to the final machining operation.

In the machine shop, a series of computerized Machining Lines (EU66) and a Perforation Line (EU67) machines each casting to the correct specifications and tolerances. Particulate emissions generated from the dry lathes, milling, and drilling operations are ducted to a series of fabric filters (CU13a-CU13j) that vent into the building. Emissions from these fabric filters are presumed to vent to atmosphere through stack ST16 which exhausts from the Paint Line #1 Booth Filter. Iron chips generated from the dry lathe, milling and drilling operations are collected as scrap steel and sent back to the melt shop and reused as internal scrap.

A low-VOC rust preventative may be applied to the casting prior to storage (EU82).

2.8 Painting

The painting operations are shown in Figure 2-6. Before shipping, each brake rotor is coated with a zinc coating. Two types of zinc coating operations are used. In one coating process, castings enter one of two lines, Paint Line #3 or Paint Line #2 (EU68-EU69), each consisting of an induction heating unit followed by a paint booth, then a cooling unit.

In an alternative coating process, castings enter Paint Line #1 (EU71) which applies a solids-based coating, followed by a preheater and final induction heater to cure the zinc coating.

All three paint lines are fitted with individual filters (CU14-CU15 and CU17) and ducted to stacks ST15A, ST15B and ST16, respectively.

2.9 Utilities

Utility operations are presented in Figure 2-7. The refractory lining of the ladles and furnaces are subjected to extreme wear and stress throughout the casting process and must be routinely replaced. Refractory relining of the induction furnaces and pouring furnace must be conducted in place. The new refractory lining is installed into a furnace by inserting a mold into the furnace and filling the space between the mold and the furnace wall with a refractory slurry. To cure the refractory lining, the mold inserts are removed once the refractory has set, and a portable natural gas burner (EU18) is lowered into the furnace, and the heat cures the new refractory lining.

Relining transport ladles is accomplished in the refractory repair area in the same manner using a mold insert and portable natural gas burners (EU05-EU06). The estimated heat input capacity of each refractory curing burner is 8.5 MMBtu/hr.

Three diesel fired emergency generators (EU72-EU74) provide backup emergency electrical in the event of a main electrical supply power failure.

A 1,000 gallon above ground diesel storage tank (EU75) is located on site and used to refuel company vehicles. Other liquid chemicals are received and stored in totes and drums.

Section 3
Emission Calculations

Appendix C includes a compilation of historical performance testing conducted at the site. See the Table 1-13 and 1-14 "Comments on 2025 Proposed Limits" column for information on how the historical testing was used to support the provided emission information. In summary, for particulate matter, the 95th percentile confidence interval was used to insure BACT emission limitations were likely to be met during subsequent testing. For VOC and CO, the 95th percentile confidence interval was used to determine appropriate emission factor.

- Appendix D: Presents the facility's potential emissions, reflecting worst-case scenarios for all relevant pollutants and processes.
- Appendices E and F: Contain emission factor-based calculations of uncontrolled and controlled emissions, respectively. These support the completion of DAQ Form DEP7007N, providing necessary data for both uncontrolled and post-control scenarios.
- The FWNA response to Comments may be of benefit in describing calculations and includes a suggested markup of the existing permit for DAQ use. The permit markup does not address emission units that were recently determined not to be installed. These are all identified in Tables 3-1 through 3-3.

The basis for all equipment capacities and emission factors can be found on each individual worksheet.

3.1 Potential to Emit Emission Calculations

This section outlines how potential emissions from the proposed project were quantified. Detailed calculations are provided in Appendix D, and the resulting hourly and annual emissions are summarized in Table 3-1 and Table 3-2. The emission unit-level calculations in Appendix D include footnotes that identify sources of emission factors and illustrate specific aspects of the calculation methodology.

Supporting documentation is included in Appendix G and Appendix V. Appendix G provides Safety Data Sheets (SDS) for materials used in the process, while Appendix V contains additional emissions-related data sources used to form the calculations.

Particulate matter emissions were estimated using a methodology based on maximum stack outlet grain loading and anticipated air flow rates to ensure conservative projections. Gaseous criteria pollutant emissions and organic hazardous air pollutant (HAP) emissions were determined using emission factors derived from site-specific performance testing, material vendor data, or other representative and credible sources.

3.1.1 Particulate Emissions

The majority of emissions sources associated with the proposed project release filterable particulate matter, primarily consisting of sand and dust particles generated during

casting operations and metal dust from melt shop and finishing activities. These emissions are typically controlled by fabric filters or baghouses.

All fabric filter systems are guaranteed by vendors to limit exhaust air concentrations to no more than 0.003 grains per dry standard cubic foot (gr/dscf). This outlet grain loading value is substantiated in Section 5 (Best Available Control Technology) of the application and is used to calculate particulate emissions by multiplying the maximum design flow rate of exhaust air with continuous operation assumed at 8,760 hours per year to reflect maximum potential emissions.

Condensable particulate matter may also be present in exhaust streams from process operations such as melting, pouring, mold cooling, and shakeout (collectively referred to as PCS), due to incomplete combustion of organic materials in molds or cores. Additionally, natural gas-fired burners contribute to potential condensable emissions. These factors were incorporated into the outlet grain loading assumptions. Particulate emissions may occur at several process locations, including induction furnaces, pouring stations, grinding stations, and conveyor systems. For units equipped with baghouse control, ductwork and hooding systems are designed in accordance with standard engineering practices to ensure particulate capture through primary or secondary hood systems, minimizing emissions to the workplace atmosphere.

Allowances for condensable particulate matter have been provided for any emission unit where condensable particulates are expected.

To calculate controlled PM, PM_{10} and $PM_{2.5}$ emissions (i.e., stack emissions), the application uses the same methodology as the original application. The APCD air volume (in acfm) and BACT-established outlet grain loadings (in gr/dscf) along with the stack temperature are used to determine hourly [Eq. 1] and annual [Eq. 2] stack emission rates from each control device. [differences in standard to actual barometric pressure and moisture content are negligible and therefore ignored]. Again Tables 2-2 and 2-3 identify the emission unit air pollution control assignments.

$$PM\ \left(\frac{lb}{hr}\right) = \frac{gr}{dscf} \times acfm\ \times (460°\mathrm{F} + 70°\mathrm{F})/(460°\mathrm{F} + stack\ temp°\mathrm{F})\ \text{[Eq. 1]}$$

$$PM\ (tpy) = PM\ \left(\frac{lb}{hr}\right) \times \frac{hours}{year}\ \text{[Eq. 2]}$$

Using an emission factor and an APCD control efficiency to quantify stack particulate emissions would not be appropriate as inlet conditions (inlet mass emissions, moisture content, particle size, etc.) are unknown and the relatively limited high quality emission factors.

Emphasizing the above, excluding the amine catalyst used at EU39 and EU40, control efficiencies are not used to calculate any emissions but only prepared to complete Form DEP7007N due to the relatively limited high quality emission factors and unknown control efficiencies.

3.1.2 Gaseous Criteria Pollutants and Organic HAP Emission Calculations

Hazardous Air Pollutants (HAPs), Volatile Organic Compounds (VOCs), and Carbon Monoxide (CO) emissions primarily originate from PCS operations, which include pouring, mold cooling, and shakeout activities. These emissions result from the incomplete combustion of gases produced during the introduction of molten iron into molds, the oxidation of carbon in green sand, and the thermal breakdown of organic binders in cores.

To estimate emissions from both the PCS process and the core shop, FWNA relied on methodologies developed by the Casting Emission Reduction Program (CERP)—a joint industry–EPA initiative formed in the 1990s to establish accurate emission factors and support emissions reduction strategies. Relevant published data through 2007 were used as the foundation for emission calculations.

While installed equipment has the theoretical capacity to process up to 15.0 tons per hour, such throughput is not continuously achievable due to the high maintenance demands of the system. As a result, FWNA has accepted a federally enforceable annual production limit of 80,000 tons of metal. Based on this cap and CERP-derived emission factors, the facility qualifies as a minor source of HAPs.

Paint usage also contributes to VOC and HAP emissions, and the hourly equipment capacity was determined along with the projected maximum annual usage. Safety Data Sheets (SDSs) for major raw materials, provided in Appendix G, were used to identify paint constituents and verify the presence of HAPs and VOCs in the coatings.

3.2 Uncontrolled and Controlled Emission Calculations – Form DEP7007N

Preparation of DAQ Form DEP7007N required estimating both uncontrolled and controlled potential particulate emissions on an hourly and annual basis.

Uncontrolled emissions were developed and documented in Appendix E, despite challenges posed by the limited availability and reliability of emissions data—particularly regarding the condensable fraction, which can range from negligible to significant.

Controlled emissions, presented in Appendix F, were calculated using particulate control efficiencies for each fabric filter rather than relying on the control device outlet grain loadings from Appendix D. These control efficiencies were derived by comparing the uncontrolled emissions from each source served by a given fabric filter to the estimated controlled emissions from that device, as documented in Appendix D. The resulting control efficiency was then applied to each emissions unit controlled by the respective fabric filter.

For emissions units such as the Melt and Core/Mold Baghouse Waste Dust Silo (EU17), Sand Plant Baghouse Waste Sand Silo (EU57), and Fettling Baghouse Waste Dust Silo (EU63), which receive dust from associated fabric filters, it was assumed that these units would not exist under an uncontrolled emissions scenario. To estimate throughput for these silos under controlled conditions, the stack emissions from each air pollution control device were subtracted from the calculated inlet loading to the respective baghouse, based on the uncontrolled emissions of the units served.

Additionally, a default particulate control efficiency of 99% was applied to any fabric filter that vents inside the building.

Section 4
Regulatory Analysis

4.1 Prevention of Significant Deterioration (PSD)

The FWNA iron foundry and machining operations are located in Simpson County, Kentucky which is an attainment area for all criteria pollutants. The air quality in neighboring counties is also in attainment with National Ambient Air Quality Standards (NAAQS).

The FWNA foundry is presumed one of the 28 PSD source categories and one hundred tpy of emissions of any PSD regulated pollutant (PM_{10}, NO_x, CO, SO2, or VOC) designates the facility as a major source under PSD.

As identified in Table 1-12, the foundry has the potential to emit over one hundred tpy of CO and VOC therefore the facility is designated as a major source, and the foundry construction was subject to PSD review.

Once the facility is designated as a major source other pollutants are evaluated to determine if emissions exceed their respective significant emission rates (SER). As shown in Table 1-12 SERs are exceeded for PM, PM_{10}, and $PM_{2.5}$. As a result, PM, PM_{10}, $PM_{2.5}$, CO and VOC are subject to PSD review.

This section reviews other potential applicable regulations.

4.2 National Emission Standards for Hazardous Air Pollutants (NESHAPs)

4.2.1 NESHAPS for a minor source of HAP (40 CFR 63 Subpart ZZZZZ-NESHAP for Iron and Steel Foundries Area Sources):

The rule provides emission limitations and work practices for both small foundries and large foundries. The FWNA foundry is a large foundry as defined by the rule. In summary this NESHAP requires the iron foundry to:

1) Develop a scrap management program that ensures no mercury switches are present in the scrap;
2) The scrap cannot contain chlorinated plastic material, and must be free of liquids, engine blocks, or oil filters;
3) Methanol cannot be used in the green mold process;
4) Particulate matter cannot exceed 0.1 pound per ton of metal processed from the furnace operation;
5) Opacity cannot exceed 20% from the furnace baghouse; and
6) All process baghouses for affected units must be monitored with a baghouse leak detector.

4.2.2 NESHAPS for a major and minor sources of HAP (40 CFR 63 Subpart ZZZZ-NESHAP for Stationary Reciprocating Internal Combustion Engines RICE)):

This subpart regulates HAP emissions from RICE located at major sources and area sources of HAP. FWNA installed three emergency generators and therefore is subject to this subpart. The rule requires compliance with NSPS IIII and limits non-emergency operation to less than one hundred hours per year.

4.2.3 Subpart CCCCCC—National Emission Standards for Hazardous Air Pollutants for Source Category: Gasoline Dispensing Facilities

This rule regulates gasoline storage tanks at area sources by imposing certain emission limits and management practices. FWNA no longer plans to install a gasoline tank and therefore this rule is not applicable.

4.2.4 Subpart XXXXXX—National Emission Standards for Hazardous Air Pollutants Area Source Standards for Nine Metal Fabrication and Finishing Source Categories

This rule regulates various metal product industries requiring certain operational practices that would reduce metal HAP emissions. The rule is not applicable to the FWNA foundry because its operation does not fit any category described in Table 1 of the rule.

4.2.5 Subpart HHHHHH—National Emission Standards for Hazardous Air Pollutants: Paint Stripping and Miscellaneous Surface Coating Operations at Area Sources

This rule applies to area sources where surface coating of metal occurs, which does apply to the FWNA foundry. However, the rule focuses on regulating emissions of certain HAP metals namely, Chromium, Lead, Manganese, Nickel, or Cadmium. The coating used at the FWNA finishing operations will be a zinc coating and does not contain any of these metals, at least not to the degree that makes it applicable to the rule (<0.1% for each metal). FWNA will continue to document that all coatings used has metal content less than this concentration.

4.3 New Source Performance Standards (NSPS)

4.3.1 40 CFR 60 Subpart Z—Standards of Performance for FerroalloyProduction Facilities

40 CFR 60 Subpart Z, Section §60.260 - Applicability and designation of affected facility:
(a) The provisions of this subpart are applicable to the following affected facilities: Electric submerged arc furnaces which produce silicon metal, ferrosilicon, calcium silicon, silicomanganese zirconium, ferrochrome silicon, silvery iron, high-carbon ferrochrome, charge chrome, standard ferromanganese, silicomanganese, ferromanganese silicon, or calcium carbide; and dust-handling equipment.

Since the FWNA foundry utilizes electric induction furnaces to melt scrap steel and keep the iron molten and not arc furnaces this rule does not apply.

4.3.2 40 CFR 60 Subpart IIII - Standards of Performance for StationaryCompression Ignition Internal Combustion Engine

This rule was finalized on July 11, 2006. It provides performance standards for diesel stationary compression ignition (CI) engines, including emergency engines that commence reconstruction or modification after the proposal date of July 11, 2005, or construction of a new engine after April 1, 2006. The rule provides performance standards for both engine manufacturers and operators. Engine operators must meet the specified emission standards and fuel type specifications in the rule. FWNA has installed three emergency generators and therefore FWNA is subject to this subpart. Other than required for maintenance purposes, these generators only operates when there is a power outage at the facility. The purchased engines are in compliance with 40 CFR 60.4202 which specifies required emission standards for emergency engines. The engines will continue to be limited to run a total of one hundred hours per year of non-emergency operation.

4.4 State Specific Rules

The FWNA facility is located in Simpson County, which is in the Commonwealth of Kentucky, South Central Kentucky Intrastate Air Quality Control Region.

Several state specific rules that are potentially applicable to this facility are discussed below.

4.4.1 401 KAR 51:010 Attainment Status Designations

The FWNA facility is located in Simpson County which has air quality standards for all regulated pollutants that are “Better than standard” and the county is not subject to additional non-attainment compliance requirements.

4.4.2 401 KAR 51:017. Prevention of Significant Deterioration of Air Quality.

The facility’s PTE emissions are such that the facility is subject to this regulation. The facility will continue to comply with this regulation.

4.4.3 401 KAR 52:020. Title V Permits.

The facility’s PTE emissions are such that the facility is subject to this regulation. The facility will continue to comply with this regulation.

4.4.4 401 KAR 52:050. Permit Application Forms.

The facility will complete Kentucky "Forms DEP7007AI to DD, Permit Application to Construct or Operate an Air Contaminant Source" as found in this permit application.

4.4.5 401 KAR 55:005. Significant Harm Criteria.

The purpose of this chapter is designed to prevent ambient pollutant concentrations at any location from reaching the following levels which could cause significant harm to the health of persons. The FWNA facility will continue to comply with this requirement.

4.4.6 401 KAR 55:020. Abatement Strategies.

The FWNA facility will prepare, when requested by the director in writing, standby plans for reducing the emission of air pollutants during episode periods (air pollution alert, warning, and emergency). Standby plans shall be designed to reduce or eliminate emission of air pollutants in accordance with the objectives set forth in Sections 2 to 4 of this administrative regulation.

4.4.7 CFR Part 61 National Emission Standards for Hazardous Air Pollutants.

The FWNA facility does not emit pollutants regulated under 40 CFR 61.01 through 61.139 and 61.160 through 61.358, Subparts A through L and N through FF and is therefore not subject to this regulation.

4.4.8 401 KAR 59:005. General Provisions.

The provisions of this chapter apply to the owner or operator of any new source for which a standard of performance has been promulgated. The FWNA facility will continue to comply with the requirements of this chapter, including Performance Tests, Notification and Recordkeeping, and Monitoring Requirements.

4.4.9 401 KAR 59:010. New Process Operations.

The provisions of this administrative regulation apply to each affected facility or source, associated with a process operation, which is not subject to another emission standard with respect to particulates in this chapter. The FWNA facility will continue to comply with the following Standard for Particulate Matter.

(1) Opacity standard: No person shall cause, suffer, allow, or permit any continuous emission into the open air from a control device or stack associated with any affected facility which is equal to or greater than twenty (20) percent opacity.

(2) Mass emission standard: For emissions from a control device or stack no person shall cause, suffer, allow, or permit the emission into the open air of particulate matter from any affected facility which is in excess of the quantity specified in Appendix A to this administrative regulation.

Interpolation of the data for process weight rates up to 60,000 lb/hr shall be accomplished by use of the equation:

$$E = 3.59P^{0.62}$$

and interpolation and extrapolation of the data for process weight rates in excess of 60,000 lb/hr shall be accomplished by the use of the equation:

$$E = 17.31P^{0.16}$$

Where: E = rate of emission in lb/hr and P = process weight rate in tons/hr.

The FWNA facility will continue to comply with the requirements of this regulation.

4.4.10 401 KAR 59:050. New Storage Vessels for Petroleum Liquids.

This rule requires specific performance standards for operation of petroleum storage tanks. It applies only if the total storage is greater than 40,000 gallons. Since the FWNA facility will store less than that, this rule does not apply.

4.4.11 401 KAR 59:105. New Process Gas Streams.

The provisions of this administrative regulation shall apply to each affected facility which means any process gas stream which is not elsewhere subject to a standard of performance within this chapter with respect to hydrogen sulfide, sulfur dioxide, or carbon monoxide.

The FWNA facility does not generate a waste gas stream containing hydrogen sulfide or sulfur dioxide. As regards to CO, the rule only applies if the facility emits more than 1,000 tpy of CO and is in a non-attainment area. Neither of these conditions are true and therefore FWNA is not subject to this regulation.

4.4.12 401 KAR 59:225. New Miscellaneous Metal Parts and Products Surface Coating Operations.

The FWNA facility is an "Affected facility" as it has a coating line located at an original equipment manufacturing industry which applies coatings to metal substrates not elsewhere subject to administrative regulation, and the facility is located in a county designated attainment for ozone in 401 KAR 51:010.

Standard for VOCs: No person shall cause, allow, or permit an affected facility to discharge into the atmosphere more than fifteen (15) percent by weight of the VOCs net input into the affected facility.

The FWNA facility is exempted from this regulation based on the following:

> (b) Less than 0.42 kg/l of coating (three and five-tenths (3.5) lb/gal). The VOC content of FWNA coatings is: 3.4 lb/gal or less.

4.4.13 401 KAR 60:005. 40 CFR Part 60 standards of performance for new stationary sources.

The FWNA facility is subject to the NSPS rules discussed in Section 4.3.

4.4.14 401 KAR 63:002. 40 CFR Part 63 national emission standards for hazardous air pollutants.

The FWNA facility is subject to the NESHAPs discussed in section 4.2.

4.4.15 401 KAR 63:005. Open burning.

This administrative regulation establishes requirements for the control of open burning. The FWNA facility will continue to comply with the requirements of this regulations.

4.4.16 401 KAR 63:010. Fugitive Emissions.

Under this Standards for Fugitive Emissions. (1) No person shall cause, suffer, or allow any material to be handled, processed, transported, or stored; a building or its appurtenances to be constructed, altered, repaired, or demolished, or a road to be used without taking reasonable precaution to prevent particulate matter from becoming airborne; (2) No person shall cause or permit the discharge of visible fugitive dust emissions beyond the lot line of the property on which the emissions originate; (3) When dust, fumes, gases, mist, odorous matter, vapors, or any combination thereof escape from a building or equipment in such a manner and amount as to cause a nuisance or to violate any administrative regulation, the secretary may order that the building or equipment in which processing, handling and storage are done be tightly closed and ventilated in such a way that all air and gases and air or gas-borne material leaving the building or equipment are treated by removal or destruction of air contaminants before discharge to the open air.

In addition, (3) at all times when in motion, open bodied trucks, operating outside company property, transporting materials likely to become airborne shall be covered, and; (4) No one shall allow earth or other material being transported by truck or earth moving equipment to be deposited onto a paved street or roadway.

The FWNA facility will continue to comply with the requirements of this regulation and in addition will continue to ensure that all internal roadways used for truck traffic are paved and these roadways cleaned on a regular basis.

4.4.17 401 KAR 63:020. Potentially Hazardous Matter or Toxic Substances.

FWNA is subject to the provisions of this administrative regulation because it emits or may emit potentially hazardous matter or toxic substances, provided such emissions are not elsewhere subject to the provisions of the administrative regulations of the Division for Air Quality.

FWNA will continue to control potentially hazardous matter and toxic substances. It will not allow the facility to emit potentially hazardous matter or toxic substances in such quantities or duration as to be harmful to the health and welfare of humans, animals, and plants. The FWNA facility will continue to comply with the requirements of this regulation as shown in Section 6 of this document.

4.4.18 401 KAR 68:010. Chemical Accident Prevention - General provisions.

The FWNA facility does not store or use chemicals in quantities which make them subject to Federal regulation 40 CFR Part 68 - General provisions for chemical accident prevention and risk management. Therefore, this regulation does not apply to the facility.

Section 5
BACT Analysis

5.1 Changes from Prior Application

As discussed in Section 1, this document provides an application to correct Air Quality Permit V-16-022 R1 (Air Permit) issued on November 25, 2017, to Fritz Winter North America LP (FWNA). The necessary corrections to the Air Permit were identified as a result of required performance testing, Air Permit required monitoring and recordkeeping and a detailed review of the Air Permit.

The revised permit application has been prepared to address a number of issues including necessary changes to raw material usages and emission limitations. **When compared to the previous application, the requested change in total emissions by this application is approximately the following:**

- PM emissions decrease 15 tpy
- PM_{10} emissions decrease 19 tpy
- $PM_{2.5}$ emissions decrease 2.5 tpy
- SO_2 emissions decrease less than 1 tpy
- NO_x emissions decrease 13 tpy
- VOC emissions increase of 144 tpy
- CO emissions increase of 38 tpy
- Lead emissions decrease of less than 0.25 tpy.

With the emissions change, there is limited changes to the previous BACT determinations as identified in Tables 1-13 and 1-14.

As shown in Table 1-12, BACT emission limitations identified in Table 1-13 result in a decrease of approximately 15 and 19 tpy for PM and PM_{10} respectively while $PM_{2.5}$ emissions decreased by 2.5 tpy.

Table 1-12 identifies VOC emission increases over current levels of approximately 144 tpy. The increase associated with VOC emissions are the result of the following changes:

- For Electric Induction Furnaces (EU07 through EU10), the addition of process VOCs emissions and/or secondary capture (in addition to combustion emissions identified in the original application) resulting in an increase from 0.61 to approximately 5,5 tpy.
- For Pouring #1 (EU50) and Mold Cooling (EU52), an emission factor change increased emissions from 17.3 to approximately 142 tpy.
- For Shakeout (EU53), as will be discussed below, correcting the emission factor results in an increase from 4.58 to approximately 22 tpy.
- For PUCB Coremaking #1 through #2 (EU39-EU40) correcting emission factor and increasing material usage increased emissions from 1.6 to approximately 7.8 tpy.

Table 1-12 shows overall CO potential emissions increase of 38 tpy. This CO emissions increase is predominantly resulting from additional process emissions or secondary capture (in addition to

combustion emissions identified in the original application) at the Electric Induction Furnaces (EU07 through EU10). This increases the CO emissions by 55 tpy to approximately 64 tpy at CU01/ST02.

Excluding the increase in VOC emissions, given the limited emissions increase identified above and absence of new technology and/or work practices for the pollutants of concern, there are no significant changes to the BACT analysis previously submitted as discussed in the following sections.

5.2 BACT Introduction

Sources undergoing a PSD review must apply BACT to any new or modified emission unit that emits a PSD-triggered pollutant. Federal PSD regulations define BACT as:

… an emission limitation (including a visible emission standard) based on the maximum degree of reduction for each pollutant subject to regulation under the Clean Air Act, which would be emitted from any proposed major stationary source or major modification, which the administrator on a case-by-case basis, taking into account energy, environmental, and economic impacts and other costs, determines is achievable for such source or modification through application of production processes or available methods, systems, and techniques, including fuel cleaning or treatment or innovative fuel combustion techniques for control of each such pollutant.

The determination proceeds to state that no BACT determination may be less stringent than the applicable NSPS, NESHAP, or State Implementation Plan (SIP) limits. Also, the definition allows a design or work practice to be established as BACT.

On December 1, 1987, the US EPA Assistant Administrator for Air and Radiation issued a memorandum that implemented certain program initiatives designed to improve the effectiveness of the New Source Review (NSR) programs in the confines of existing regulations and SIPs. Among these was the "top-down" method for determining BACT. The top-down process provides that available control technologies be ranked in descending order of control effectiveness. The first step of this process is to evaluate the most stringent or "top" alternative. This represents BACT, unless it can be demonstrated, and the permitting authority agrees, that technical considerations, energy, environmental, or economic impacts justify a conclusion that the most stringent technology is not "achievable" in a particular case. If the most stringent technology is eliminated in this fashion, then the next most stringent alternative is considered, and so on, until the most appropriate control strategy is selected for each source.

BACT is required for any emission unit that emits a PSD-regulated pollutant above the respective significant emission rate (SER). Table 5-1 identifies PSD-regulated pollutants exceeding the SER as particulate matter (PM), particulate matter equal to or less than 10 microns in diameter (PM_{10}), particulate matter equal to or less than 2.5 microns in diameter ($PM_{2.5}$), volatile organic compounds (VOCs) and carbon monoxide (CO). These are the same pollutants identified in the prior air permit applications.

5.3 Study Methodology

The requirement to conduct a BACT analysis is provided for in 401 KAR 51:107 Section 8 (2) and states a "new major stationary source shall apply BACT for each regulated NSR pollutant for which the source has the potential to emit in significant amounts."

401 KAR 51_001 Section 1(25) defines BACT as "an emissions limitation, including a visible emission standard, based on the maximum degree of reduction for each regulated NSR pollutant that will be emitted from a proposed major stationary source or major modification and:

(a) Is determined by the cabinet pursuant to 401 KAR 51:017, Section 8, after considering energy, environmental, and economic impacts and other costs, to be achievable by the source or modification through application of production processes or available methods, systems, and techniques, including fuel cleaning or treatment or innovative fuel combustion techniques for control of that pollutant;
(b) Does not result in emissions of a pollutant that would exceed the emissions allowed by an applicable standard codified in 40 C.F.R. Parts 60 and 61; and
(c) Is satisfied by a design, equipment, work practice, or operational standard or combination of standards approved by the cabinet, if:
    1. The cabinet determines pursuant to 40 C.F.R. 51.166(b)(12) that technological or economic limitations on the application of measurement methodology to a particular emissions unit would make the imposition of an emissions standard infeasible;
    2. The standard establishes the emissions reduction achievable by implementation of the design, equipment, work practice, or operation; and
    3. The standard provides for compliance by means that achieve equivalent results.

From the definition above, BACT is "an emission limitation," not an emission reduction rate or a specific technology. BACT is determined on a case-by-case basis and therefore does not require the installation of any specific control device. While BACT is prefaced upon the application of technologies reflecting the maximum reduction rate achievable, the result of BACT is as stated above "an emission limit."

In addition, the above BACT definition identifies that in cases where the implementation of an emission limitation is deemed infeasible, "…a design, equipment, work practice, or operation" may be prescribed as a BACT standard."

BACT is to be established at the lowest value that is achievable. However, there is an important distinction between emission rates achieved at a specific time on a specific unit, and an emission limitation that a unit must be able to meet continuously over its operating life. DC Circuit Court of Appeals, in National Lime Association v. EPA, 627 F.2d 416, 431 n.46 (D.C. Cir. 1980), stated that where a statute requires that a standard be "achievable," it must be achievable "under most adverse circumstances which can reasonably be expected to recur."[1]

Similar conclusions have been made by USEPA in previous PSD permits. USEPA has stated "Agency guidance and our prior decisions recognize a distinction between, on the one hand, measured 'emissions rates,' which are necessarily data obtained from a particular facility at a specific time, and on the other hand, the 'emissions limitation' determined to be BACT and set forth in the permit, which the facility is required to continuously meet throughout the facility's life. Stated simply, if there is uncontrollable fluctuation or variability in the measured emission rate, then the lowest measured emission rate will necessarily be more stringent than the "emissions limitation" that is "achievable" for that pollution control method over the life of the facility. Accordingly, because the "emissions limitation" is applicable for the facility's life, it is wholly appropriate for the permit issuer to consider, as

[1] Sierra Club v. USEPA (97-1686)

part of the BACT analysis, the extent to which the available data demonstrate whether the emissions rate at issue has been achieved by other facilities over a long term."[2]

It follows from above that BACT should be established at the lowest feasible emission rate recognizing that the emission unit must comply with the emission rate or limit on a continuous basis for the life of the unit or air permit. It follows then that any actual performance data gathered for an emission unit must be viewed carefully, as rarely will the data be adequate to truly assess the performance that a unit will achieve during its entire operating life. While statistical variability of actual performance can be used to infer what is "achievable," such testing requires a significant effort compiled over a significant period and that robust of a dataset is usually and largely unavailable at the time of the BACT analysis.

The BACT review is conducted using USEPA's prescribed "Top Down" method as outlined in the 13 October 1989 guidance document, "Transmittal of Background Statement on Top Down Best Available Control Technology (BACT)", issued by John Calcagni, Director, the United States Environmental Protections Agency's (USEPA's) Air Quality Management Division. The details of the study were compiled in accordance with the guidance, "Improving New Source Review Implementation," 1 December 1987, from J. Craig Potter, USEPA's Assistant Administrator for Air and Radiation, and the accompanying document "Best Available Control Technology Guidance Document, EPA Region 9, April 1987."

The following sections of the analysis present the "top-down" BACT analysis for each pollutant that exceeded the SER and is specific to each emission unit, unless otherwise specified. The five steps in such an evaluation can be summarized as follows:

Step 1. Identify all possible control technologies;
Step 2. Eliminate technically infeasible control options;
Step 3. Rank the technically feasible control technologies based upon emission reduction potential;
Step 4. Evaluate ranked control technologies based on energy, environmental, and/or economic considerations; and
Step 5. Select BACT.

The above process is typically conducted on a unit-by-unit, pollutant-by-pollutant basis. While the top-down BACT analysis is a procedural approach suggested by USEPA policy, this approach is not specifically mandated as a statutory requirement of the BACT determination. The BACT analysis has been evaluated via this "top-down" approach. The "top-down" will be further discussed below.

Economic considerations identified in Step 4 above were completed in accordance with Office of Air Quality Planning and Standard's Control Cost Manual. Supporting documentation for capital and installation costs utilized in the analyses is included in the appendices of this document.

5.4 Emission Units and Pollutants

As discussed above, BACT is required for any emission unit that emits a PSD-regulated pollutant above the respective significant emission rate (SER) with Table 5-1 identifying those regulated pollutants exceeding the SER as PM, PM_{10}, $PM_{2.5}$, VOCs, and CO.

[2] U.S. EPA Environmental Appeals Board decision, Newmont Nevada Energy Investment L.L.C. PSD Appeal No. 05-04, decided December 21, 2005. Environmental Administrative Decisions, Volume 12, Page 442.

Table 5-2 identifies each unit-that emits a PSD regulated pollutant. Because the emission rates for most PM, PM_{10} and $PM_{2.5}$-generating emission units are quantified at the stack level (see bottom of Table 5-2), Tables 2-2 and Table 2-3 provides a cross reference of Air Pollution Control Device (APCD) ID/Stack ID to Emission Unit ID and Emission Unit Name, respectively, allowing identification of all emission units subject to BACT due to their particulate emissions.

A summary of Emission Unit ID, Emission Unit Description and identification of pollutant emitted by each operation is provided in Table 5-3.

5.5 Analysis Introduction and Prioritization

The first step in conducting the analyses was to identify current emission reduction technologies and determine which operations would most likely be cost-effective to control. Therefore, a review of the RBLC was completed to identify similar operations, already in existence, using add-on controls for PM, PM_{10}, $PM_{2.5}$, VOC, and CO emissions.

The above review found several determinations for PM, PM_{10}, and $PM_{2.5}$ emission sources. Most of the determinations included the installation of a baghouse. As previously mentioned, no pouring, mold cooling, and shakeout operations were found in the RBLC using a CO and/or VOC emissions control device (excluding mold vent light-off). In addition, based on a review of the RBLC and several state permits, no PUCB core- making or mold-making operations were identified as utilizing VOC controls other than an acid scrubber for amine catalyst emissions control.

The review of the RBLC found only VOC emission control devices installed on melting (Electric Arc Furnaces (EAFs) and Cupolas). EAFs and cupolas are more significant sources of VOCs, when compared to an Electric Induction Furnace as installed and used at FWNA.

A major concern when evaluating the feasibility of emissions controls on pouring, mold cooling, and shakeout was the fact that to date no CO and/or VOC control devices were found installed on any of these operations. Given this fact and considering the potential generation of partially oxidized organic compounds and the potential formation of condensation, any control technologies must be carefully evaluated.

Also, from discussions with air pollution control device (APCD) vendors, in the event of a baghouse failure, a secondary filter system would be necessary to capture PM emissions prior to any "regenerative" VOC/CO control device. The most practical and economical of these systems would be a vessel with multiple filters, though some vendors recommended against using regenerative thermal oxidizer systems because of this potential problem. Vendors indicated that a recuperative system would more likely survive an occasional high PM loading but did indicate that such an event would not be desirable and would shorten the lifespan of the control equipment.

While the process requires a BACT determination for every emission unit, this analysis focused on those production scenarios that would have the largest emissions rates since it is less likely that operations with smaller emissions would be cost-effective to control. The operations and their respective estimated annual PM/PM_{10}/$PM_{2.5}$, VOC, and CO emissions are summarized in Table 5-2.

5.6 BACT Process and Foundry Specific Considerations

During preparation and subsequent evaluation of the BACT analysis, a number of considerations and concerns were identified including those discussed below:

5.6.1 RBLC Information Quality

Any critical BACT determining information identified in the RBLC must be verified before use. For example, Indiana Department of Environmental Management was contacted to clarify relatively low VOC emissions limits listed in the RBLC for the PUCB core-making operations identified at two facilities in Indiana. **From these discussions, it was learned that the VOC emissions limits are only intended to address binder system catalyst emissions.** VOC emissions from the resin and other potential organic materials used in the process were not addressed in the permit. FWNA has installed similar controls for the VOC emissions from the PUCB catalyst with control efficiency similar to the Indiana permit requirement.

Regarding PM, PM_{10} and $PM_{2.5}$ RBLC determinations, care must be exercised to investigate whether those emission rates include condensable portion and whether a test method that would measure condensable matter (e.g., USEPA Method 202) was specified in the permit.

Finally, it is important to determine whether compliance has been demonstrated with any particular emission limitation. **This concern actually manifested itself in the previous FWNA air permit application where a Waupaca RBLC VOC determination for a shakeout was used. While FWNA was found to not be in compliance with that emission rate, it has been determined that the Waupaca facility cannot meet that emission rate as well.**

5.6.2 RBLC Identified Pollutants and Emission Rates

It is apparent from review of the RBLC that CO and VOC emissions from pouring, mold cooling, and shakeout operations have been inconsistently identified in air permit applications including several facilities in the RBLC that did not identify any CO or VOC emissions from these operations. This reduces the number of RBLC determinations available for review.

It is important to recognize that a number of the VOC emission limitations identified for the above operations are the emission factor identified in WebFIRE as opposed to the resultant emission rate from a detailed BACT evaluation.

5.6.3 CO and VOC Emission Quantification and Variability

Another important project issue was determining representative VOC and CO emission factors for this analysis. VOC emission factors published in USEPA's AP-42 and WebFIRE for iron foundries are of "poor" or "unknown" quality. In the case of CO, no emission factors exist in AP-42 or WebFIRE for pouring, mold cooling, and shakeout operations. While FWNA has conducted testing, the dataset is limited.

Following along with the above, it is important to consider material and process variability when comparing CO emission from iron pouring and mold cooling operations. CO emissions may vary due to metal type, pouring temperature, raw materials, throughput rate, and other product or production parameters.

Therefore, it is very difficult to compare CO emissions from individual pouring and mold cooling operations on a pound per hour basis without an understanding of the underlying process. While not perfect, it is prudent to compare operations pouring the same metal (e.g., iron) with similar raw materials (such as mold binder type) in terms of pounds of emission per ton of iron poured. This would at least consider metal type (which gives a good indication of pouring temperature) and production rate.

5.6.4 Commingling of Process Emissions

For successful operation of a fabric filter, emissions from a single foundry operation are usually vented to multiple air pollution control devices. This ensures each fabric filter encounters particles whose size is more widely distributed and that any moist or particles with adhesive properties are not all vented to a single fabric filter The activities of commingling process emissions promote the development of a superior cake and assists with the release of the cake from the filtering media.

Therefore, when reviewing a single foundry RBLC determinations, it must be recognized that the entry is usually not from a single operation but for a commingled exhaust from multiple operations. This commingling not only impact RBLC determinations for particulates but any gaseous pollutant being evaluated.

5.6.5 Air Volume and Capture Rates

Because of the nature of foundry operations, emission unit ventilation requirements due to equipment configuration and access typically require high exhaust airflow rates with a portion of the emission remaining fugitive. The RBLC does not provide an assessment of the capture system or capture rate, which could alter the results of any BACT and the corresponding compliance demonstration.

5.7 Control Technology Feasibility

This section discusses in more detail the "top-down" BACT analysis that will be conducted for each pollutant that exceeded the SER. The five steps in such an evaluation can be summarized as follows:

- **Step 1.** Identify all possible control technologies;
- **Step 2.** Eliminate technically infeasible control options;
- **Step 3.** Rank the technically feasible control technologies based upon emission reduction potential;
- **Step 4.** Evaluate ranked control technologies based on energy, environmental, and/or economic considerations; and
- **Step 5.** Select BACT.

5.7.1 Step 1 – Identify All Control Technologies

The primary objective of Step 1 is to identify all "available" control options for the emission unit in question. Available control options are defined in the 1990 Draft NSR Workshop Manual as:

> … those air pollution control technologies or techniques with a practical potential for application to the emissions unit and the regulated pollutant under evaluation. Air pollution control technologies and techniques include the

> application of production process or available methods, systems, and techniques, including fuel cleaning or treatment or innovative fuel combustion techniques for control of the affected pollutant. This includes technologies employed outside of the United States. As discussed later, in some circumstances inherently lower-polluting processes are appropriate for consideration as available control alternatives. The control alternatives should include not only existing controls for the source category in question, but also (through technology transfer) controls applied to similar source categories and gas streams, and innovative control technologies. Technologies required under lowest achievable emission rate (LAER) determinations are available for BACT purposes and must also be included as control alternatives and usually represent the top alternative.

A lower-polluting process or practice is considered applicable if it has been demonstrated for a similar emission unit or application. An add-on control is considered applicable if it can properly function given the physical characteristics of the pollutant stream being controlled (i.e., gas stream temperature, pollutant concentration, etc.).

Potentially applicable control options were surveyed. These included control technologies that have been used in other source categories and countries. Control technologies identified by LAER determinations were also included as available control technologies.

Based on the guidelines provided in the USEPA Draft New Source Review Workshop Manual document, a comprehensive list of available control technologies was developed for this permit application.

5.7.2 Step 2 – Eliminate Technically Infeasible Options

The purpose of Step 2 is to evaluate the technical feasibility of the control technology options identified in Step 1. Control technologies that have been installed and operated successfully on the type of emission unit under review are considered demonstrated and technically feasible. Control technologies that are not applicable or not available are determined to be technically infeasible. For a technology that has not been demonstrated for a particular type of emission unit, the Draft New Source Review Workshop Manual provides the following guidance:

> Two key concepts are important in determining whether an undemonstrated technology is feasible: “availability” and “applicability.” As explained in more detail below, a technology is considered “available” if it can be obtained by the applicant through commercial channels or is otherwise available within the common sense meaning of the term. An available technology is “applicable” if it can reasonably be installed and operated on the source type under consideration. A technology that is available and applicable is technically feasible.

A control technique is considered available, within the context presented above, if it has reached the licensing and commercial sales stage of development. A source would not be required to experience extended time delays or resource penalties to allow research to be conducted on a new technique. Neither is it expected that an applicant would be required to experience extended trials to learn how to apply a technology on a new and dissimilar source type.

Consequently, technologies in the pilot scale testing stages of development would not be considered available for BACT review. An exception would be if the technology were proposed and permitted under the qualifications of an innovative control device consistent with the provisions of 40 CFR 52.21(v) or, where appropriate, the applicable SIP.

Commercial availability by itself, however, is not necessarily sufficient basis for concluding a technology to be applicable and therefore technically feasible. Technical feasibility, as determined in Step 2, also means a control option may reasonably be deployed on or "applicable" to the source type under consideration.

Technical judgment on the part of the applicant and the review authority is to be exercised in determining whether a control alternative is applicable to the source type under consideration. In general, a commercially available control option will be presumed applicable if it has been or is soon to be deployed (e.g., is specified in a permit) on the same or a similar source type. Absent a showing of this type, technical feasibility would be based on examination of the physical and chemical characteristics of the pollutant-bearing gas stream and comparison to the gas stream characteristics of the source types to which the technology had been applied previously.

Deployment of the control technology on an existing source with similar gas stream characteristics is generally sufficient basis for concluding technical feasibility barring a demonstration to the contrary.

5.7.3 Step 3 – Rank Remaining Technically Feasible Control Options

The third step in the five step top-down BACT evaluation process involves ranking of the technically feasible control options determined in Step 2 from most effective to least effective in terms of emissions reduction potential. Step 3 also determines the energy, economic, and environmental impacts associated with the technically feasible control options, which are more fully evaluated in Step 4 of the process.

Ranking control options involves the selection of appropriate units of emissions for comparison between types of control technologies and emission units.

Achievable emission limits were determined for each of the control technology options based on engineering estimates, published literature, and testing data from existing sources. After establishing performance levels for the technically feasible control technologies, control technology alternatives were ranked by their demonstrated emissions reduction performance. Also, as indicated in the Draft New Source Review Workshop Manual regarding selection of the defined "top" control technology alternative:

> … an applicant proposing the top control alternative need not provide cost and other detailed information in regard to other control options. In such cases the applicant should document that the control option chosen is, indeed, the top, and review for collateral environmental impacts.

5.7.4 Step 4 – Evaluate Remaining Control Technologies

Step 4 of the five step top-down BACT evaluation process involves evaluating the suitability of the ranked control technology options under Step 3, based on energy, economic, and environmental impacts of use of the control technology. The following excerpt, taken from the Draft New Source Review Workshop Manual, explains the general evaluation process of Step 4:

> "If the applicant accepts the top alternative in the listing as BACT, the applicant proceeds to consider whether impacts of unregulated air pollutants or impacts in other media would justify selection of an alternative control option. If there are no outstanding issues regarding collateral environmental impacts, the analysis is ended, and the results proposed as BACT. In the event that the top candidate is shown to be inappropriate, due to energy, environmental, or economic impacts, the rationale for this finding should be documented for the public record. Then the next most stringent alternative in the listing becomes the new control candidate and is similarly evaluated. This process continues until the technology under consideration cannot be eliminated by any source-specific environmental, energy, or economic impacts which demonstrate that alternative to be inappropriate as BACT."

The energy impacts analysis determines whether the use of the control technology results in any significant or unusual energy penalties or benefits. The economic impacts analysis evaluates average and incremental cost effectiveness to determine if use of the control technology would result in a negative economic impact. The evaluation of environmental impacts considers the site-specific environmental impacts of use of the control technology option, involving issues such as waste generation, water use and discharge, visibility impacts, emissions of additional pollutants, etc.

5.7.5 Step 5 – Selection of BACT

The highest ranked and most effective control option not eliminated in Step 4 for energy, economic, or environmental impacts is selected and proposed as BACT for that pollutant and emission unit.

These procedures were followed to develop a BACT assessment for each major piece of equipment in the process for each of the three PSD triggering pollutants. This analysis is presented in the following sections by pollutant.

Table 5-6, 5-12 and 5-21 provide a summary of the conclusion and basis for each BACT determination.

5.8 Particulate BACT

Almost all of the emission sources in the iron foundry process emit particulate matter in one form or another. The main source of the particulate is the sand used to form the mold. Particulate is also generated from the finishing and machining of the finished parts and the final coating application.

In the case of the machining, particulate is formed from the fine metal dust during grinding and milling operations. This particulate is generally in filterable form, but a

significant amount of condensable particulate can be generated from the pouring, cooling and shakeout operation and is a result of incomplete combustion of the organic compounds emitted from the mold in this step. Too much less of a degree condensable particulate is also generated from the combustion of natural gas in the melt shop and the utilities area.

As stated previously, information from the prior application will be retained as possible and especially for those emission units where emission increases are not requested.

5.8.1 Step 1 – Identify All Control Technologies

Available control technologies with the practical potential for application to the emission unit are identified in Step 1. The application of demonstrated control technologies in other similar source categories to the emission unit of concern can also be considered. While identified technologies may be eliminated in subsequent steps in the analysis based on technical and economic infeasibility or environmental, energy, economic or other impacts, control technologies with potential application to the emission unit under review are identified in this step.

Under Step 1 of the BACT analysis, the following resources are typically consulted when identifying potential control technologies or work practices:

- Applicable NESHAP, NSPS and State Rules
- U.S. EPA's RBLC database;
- Determinations of BACT by regulatory agencies for other similar sources or air permits and permit files from federal or state agencies;
- Federal and/or state regulatory requirements;
- Engineering experience with similar control applications;
- Information provided by air pollution control equipment vendors with significant market share in the industry; and
- Review of literature from industrial technical or trade organizations.

NESHAP Review

As stated in Section 4, FWNA is subject to the Foundry Area Source Rule and is defined by the rule as a "new" source and a "large" foundry. As such, FWNA is subject to the following PM requirements:

- Per 40 CFR §63.10895(c)(2) the facility must not discharge to the atmosphere emissions from any metal melting furnace or group of all metal melting furnaces that exceed 0.1 pounds of PM per ton of metal charged or 0.008 pounds of total metal HAP per ton of metal charged.
- Per 40 CFR §63.10895(e), the facility must not discharge to the atmosphere fugitive emissions from foundry operations that exhibit opacity greater than 20 percent (6-minute average), except for one 6-minute average per hour that does not exceed 30 percent.

RBLC Review

A review of the RBLC was conducted in November 2024. The review assessed permits from the time period of January 2006 through November 2024. Research of the historical and transient

databases was not conducted because the control determinations in those databases would precede the implementation of the major and area source National Emission Standards for Hazardous Air Pollutants (NESHAPs) for iron foundries and generally would not be as stringent on emission limits or control technology requirements.

Table 5-5 includes $PM/PM_{10}/PM_{2.5}$ determinations contained in the RBLC. The RBLC identified fabric filters/baghouses as the method of control for filterable particulate matter emissions. No control technology was identified for condensable particulate matter.

RBLC process numbers correspond to the following:

Cupola Furnace	81.410
Induction Furnace	81.420
Desulfurization	81.430
Sand, Core and Mold Making Process	81.440
Casting and Pouring Processes	81.450
Shakeout Processes	81.460
Other Iron Foundry Processes	81.490

For particulate matter from the coating operations, in addition to process number 81.490, the RBLC was reviewed for process number 41.013. This yielded the Fritz Winter North America Facility as the only facility to coat iron castings.

While the RBLC only identified fabric filters/baghouses for the emission units of concern, potential control technologies for filterable particulate matter include the following:

- Cyclones
- Wet scrubber
- Electrostatic precipitators (ESPs)
- Cartridge collectors
- Fabric Filters (Baghouses)

These technologies are discussed below.

<u>Cyclones</u>
A cyclone is a simple mechanical device that uses centrifugal and inertial forces on particulate laden exhaust within cylindrical container. Large particles hit the wall of the cyclone and fall to the bottom where they can be collected. Unless all the particles are of a large diameter (>10 microns) the cyclone is not considered the most efficient collection devices. Cyclones are typically used as a pre-cleaning control used to reduce the particulate concentration in a gas stream prior to entering a second more effective control device.

<u>Wet scrubber</u>
Wet scrubbers used for particulate are generally Venturi scrubbers. In Venturi scrubber particles are removed through inertial impaction when they impact upon water droplets traveling at a high velocity through the throat of the scrubber. Wet scrubbers are useful in removing particulates that are sticky and/or hygroscopic, combustive, corrosive and explosive, hard to remove in dry form, in presence of soluble gases, and have a high moisture content. Venturi

scrubbers and spray tower wet scrubbers are types of wet scrubbers generally employed in combustion of solid fuels.

Electrostatic Precipitators (ESPs)
Electrostatic precipitators utilize electrical forces to transfer particulate onto a collector plate. By passing flue gases laden with particulate through a gaseous ion region, known as a corona, particles are given a charge. The charged particles are forced onto the collector plate by an electrical field generated by electrodes kept at high voltage. In dry ESPs, the collected particles are knocked off into a hopper by a sonic horn or mechanically, in a manner that does not introduce them back into the gas stream. Wet ESPs remove PM buildup with intermittent or continuous washing with water.

Cartridge Collectors
Cartridge collector filters utilize paper or nonwoven fibrous media set in an inner and outer wire frame structure. The filter is often pleated to increase surface area. The exhaust is passed through the filter and as particulate is collected on its surface, efficiency increases.

Fabric Filters (Baghouses)
A fabric filter is one of the most efficient means of separating particles from a gas stream. The advantage of fabric filters is that the efficiency is largely insensitive to the physical characteristics of the gas stream and changes in the dust loading. Fabric filters are the industry standard for iron foundry particulate controls.

One type of fabric filter is the baghouse with both positive and negative pressure baghouses being used in the industry. Positive pressure baghouses operate at an internal pressure greater than atmospheric. In this configuration, the exhaust fans are located before the baghouse (i.e., on the “dirty side”) and pull the air from the process, then push the air through the baghouse. These systems may vent to ambient air through a continuous ridge vent instead of a stack.

Negative pressure baghouses operate at an internal pressure less than atmospheric. In this configuration, the exhaust fans are located after the baghouse (i.e., on the “clean side”), pull the air from the process through the baghouse, and exhaust to the ambient air through a central stack.

5.8.2 Step 2: – Eliminate Technically Infeasible Options

Below presents a discussion regarding the elimination of certain identified control technologies.

Cyclones
As mentioned earlier, cyclones are typically used as a pre-cleaning control and thus would have to be placed prior to the baghouse. As a pre-cleaner, cyclones are designed to remove more than 80% of particles greater than twenty microns in diameter. The majority of the particulate in the various foundry exhaust streams will be smaller than twenty microns and thus will not be an effective pre-control. Cyclones are a technically infeasible option and will not be analyzed further.

Wet Scrubbers

Wet scrubbers are technically feasible but have many disadvantages compared to fabric filters, which can achieve better levels of particulate control. Scrubber systems have very high pressure drops that result in unacceptable system operating costs. They also required water treatment and sludge disposal, which are not necessary with the other particulate control options.

Wet scrubbers were more commonly used in iron foundries to control exhaust from a cupola furnace. In that application a wet scrubber makes sense because in a cupola fuel is being burned in the furnace where the metal is melted. Typically, the fuel used is coal and since considerable amount of sulfur dioxide is released from such furnaces, the scrubber can remove that as well as particulate. Since FWNA will use an induction furnace that has negligible gaseous emissions and since sand and dust recovery is an essential part of the FWNA process, wet scrubbers are considered not technically feasible to the FWNA process and will not be further analyzed.

ESPs

ESPs are not technically feasible for the FWNA operation. A key parameter is the composition of the particles to be collected. Iron compounds adhere very strongly to the collection plate of the ESP (due to their electromagnetic properties). They are, therefore, very difficult to remove and thus reduce ESP efficiency. Zinc and other metal compounds tend to foul ESP electrodes, also reducing effectiveness. In addition, ESPs have a relatively high capital cost and are greatly affected by sensitivity to the variations in flow rate, solids loading, and temperature fluctuations inherent in batch operations like that seen in an iron foundry. For these reasons ESPs are considered technically infeasible and not considered further.

Cartridge Collectors

Cartridge collectors function optimally with a low loading of dry, non-sticky dust flowing at a low rate of 10,000 cubic feet per minute (cfm) or less and in low humidity. However, for the FWNA process typical air flow rates are in the range of approximately 100,000 dry standard cubic feet per minute (dsfcm). In addition, some of the sand and dust that would be collected on the cartridge may have residual resin material from the core bonding materials that would tend to obstruct the cartridge making it unusable. Due to these limitations, cartridge collectors are only viewed as technically feasible for the machining operations.

Fabric Filters (Baghouses)

Fabric filters and generally baghouses are the industry standard for iron foundries particulate controls and is considered further in the next step.

5.8.3 Step 3: – Ranking Remaining Control Technologies by Control Effectiveness

Now that the control technology has been selected the emission limit needs to be assessed based on this technology.

Using the current state of the art bags and overall design, most vendors will guarantee an outlet grain loading of 0.005 grains per dscf (gr/dscf) for filterable particulate emissions. EPA in developing the emission standards for new “area sources” of HAPs as discussed above established emission levels from melting operations of 0.1 lb/ton of metal. This level of control can only be met with certain baghouse designs.

5.8.4 Step 4: Evaluate Most Effective Controls and Document Results

Table 5-5 provides the PM, PM_{10} and $PM_{2.5}$ RBLC entries for all foundry operations from January 2006 through November 2024 and are sorted by process number.

Prior to 2016, typically the permitted level for all of the operations has been 0.005 gr/dscf. One foundry, Rochester Metal Products, Inc. was permitted at a lower level of 0.003 gr/dscf. We contacted the state agency (IDEM), and they confirmed Rochester Metal Products, Inc. was achieving those levels but for filterable PM only.

ASAMA foundry in Wheland, Georgia has a baghouse with an identified outlet loading of 0.001 gr/dscf. This baghouse only controls emissions from minor sources such as silo bin vents. At this same foundry, the permit levels for the main source of emissions is 0.005 gr/dscf and for one application, the shot blasting area is 0.008 gr/dscf.

Following 2016, there are newer installations with outlet loading limitations in the range of 0.001 to 0.003 gr/dscf, depending on expected contribution of condensable particulates. Baghouses with higher inlet loading from melting, pouring, cooling and shakeout have RBLC determinations on the higher side of this range. Operations with no expected condensable fraction (e.g., grinding, shotblasting) have RBLC determinations on the lower side of the range.

5.8.5 Step 5: Select BACT

BACT cannot be less stringent than the applicable NSPS, NESHAP or SIP limit. Since the FWNA foundry will be a minor source of HAPs the applicable NESHAP standard is Subpart ZZZZZ. This subpart limits the filterable particulate emissions from the melt shop baghouse to 0.1 lb/ton of metal.

Table 5-6 provides the BACT limit and justification for each emission unit.

5.9 CO BACT

In addition to the CO emission from the combustion of fuels (natural gas throughout a number of operations and diesel fuel used at the emergency generators), the main sources of CO from the FWNA are the melting, pouring, cooling and shakeout (PCS) operations.

At the PCS operations CO is generated during partial oxidation of the gases that leave the mold during the pouring operation. These gases contain various organic compounds created from the breakdown of binders in the core and the carbon in the green sand mold. This CO is first emitted at the pouring operation but continues during cooling and shakeout.

The majority of the CO emissions are released via the Core/Mold Baghouse stack (CU08/ST09) as a result of pouring and cooling. CO emissions are also generated during melting and released via the Melt Baghouse stack (CU01/ST02) and during shakeout with those being emitted via the Sand Plant Baghouse (CU06/ST07) stack.

This BACT analysis leaves the original text that examines potential add-on controls to reduce the CO that is generated from pouring, cooling and shakeout but adds an analysis to determine BACT from the electric induction furnaces.

5.9.1 Step 1 – Identify All Control Technologies

Available control technologies with the practical potential for application to the emission unit are identified in Step 1. The application of demonstrated control technologies in other similar source categories to the emission unit of concern can also be considered. While identified technologies may be eliminated in subsequent steps in the analysis based on technical and economic infeasibility or environmental, energy, economic or other impacts, control technologies with potential application to the emission unit under review are identified in this step.

Under Step 1 of the BACT analysis, the following resources are typically consulted when identifying potential control technologies or work practices:

- Applicable NESHAP, NSPS and State Rules
- U.S. EPA's RBLC database;
- Determinations of BACT by regulatory agencies for other similar sources or air permits and permit files from federal or state agencies;
- Federal and/or state regulatory requirements;
- Engineering experience with similar control applications;
- Information provided by air pollution control equipment vendors with significant market share in the industry; and
- Review of literature from industrial technical or trade organizations.

NESHAP Review

As stated in Section 4, FWNA is subject to the Foundry Area Source Rule and is defined by the rule as a "new" source and a "large" foundry. As such, FWNA is subject to the following PM requirements:

- Per 40 CFR §63.10895(c)(2) the facility must not discharge to the atmosphere emissions from any metal melting furnace or group of all metal melting furnaces that exceed 0.1 pounds of PM per ton of metal charged or 0.008 pounds of total metal HAP per ton of metal charged.
- Per 40 CFR §63.10895(e), the facility must not discharge to the atmosphere fugitive emissions from foundry operations that exhibit opacity greater than 20 percent (6-minute average), except for one 6-minute average per hour that does not exceed 30 percent.

RBLC Review

A review of the RBLC was conducted in November 2024. The review assessed permits from the time period of January 2006 through November 2024. Research of the historical and transient databases was not conducted because the control determinations in those databases would precede the implementation of the major and area source National Emission Standards for Hazardous Air Pollutants (NESHAPs) for iron foundries and generally would not be as stringent on emission limits or control technology requirements.

Table 5-8 includes CO determinations contained in the RBLC. The RBLC identified "mold vent off gas ignition" as the method of control for carbon monoxide emissions.

The data in Table 5-8 is sorted by process number. RBLC process numbers correspond to the following:

Cupola Furnace	81.410
Induction Furnace	81.420
Desulfurization	81.430
Sand, Core and Mold Making Process	81.440
Casting and Pouring Processes	81.450
Shakeout Processes	81.460
Other Iron Foundry Processes	81.490

Potential control technologies include the following:

1. Incineration
2. Flare
3. Mold vent gas autoignition

Incineration

Incineration equipment increases the temperature of exhaust gas stream to the combustion temperature of CO. There are three types of incineration systems: recuperative, regenerative, and catalytic. In a recuperative thermal oxidizer, the exhaust enters a combustion chamber and into a heat exchanger. The heat exchanger utilizes conduction to transfer heat to the waste gas. The exhaust gas can be used to preheat incoming waste gas and/or combustion air to offer fuel savings. A regenerative thermal oxidizer (RTO) uses a direct contact heat exchanger to raise the exhaust temperature.

The heat exchanger is made up of a structured, high heat capacity media like a bed of porous ceramic packing. A regenerative catalytic oxidizer (RCO) is very similar to an RTO but uses a precious metal-based catalyst bed and the oxygen in the gas stream to reduce CO emissions to carbon dioxide (CO2). The catalyst speeds up the conversion of CO at a lower temperature than a thermal incinerator.

Flare

Flares utilizes the fuel value of the exhaust streams themselves and if present in high enough concentrations (CO or VOC), the gas can be burned at the flare tip with some type of ignition source typically at a well elevated level. The gas is burned without heat recovery and directly vented into the atmosphere.

Mold Vent Off Gas Autoignition

When the molten iron is poured onto the sand molds, organic HAP and CO are emitted when the chemicals in the mold and core vaporize or undergo pyrolysis. Emission of HAPs and CO continue to be emitted during cooling and shakeout process. These gases are concentrated into one or two vents built into the mold for the sole purpose of venting the gases generated when molten metal is poured into it. The mold off gas vents for the most part occurs almost immediately after pouring begins due to the heat caused by the molten metal.

5.9.2 Step 2: Eliminate Technically Infeasible Options

Below presents a discussion regarding the elimination of certain identified control technologies.

Incineration

In the FWNA process, an add-on incinerator could only follow a baghouse due to high particulate content in the exhaust streams. Regenerative and catalytic systems can be rendered inoperable if the particulate residuals in the exhaust stream foul the catalyst bed or ceramic media packing of the RTO. Even so placing an RCO downstream of a baghouse still may not protect the unit. Catalyst vendors state that certain compounds might poison a catalyst by reacting with the active sites on the catalyst to render it inactive. Typical elements that need to be considered are sulfur, phosphorus, silicon, and heavy metals. The latter two pollutants will be present in the exhaust. Vendors warn that even small concentrations of these elements can render a catalyst ineffective. The gas stream must be carefully characterized to make sure that poisons do not exist.

In particular vendors caution that particulate matter can mask or even poison a catalyst to render it ineffective. However, the size and physical state of the particles must be carefully considered; particles in the gas stream do not necessarily mean that RCO cannot be used. For example, coarse particles will be caught in the media bed and will not reach the catalyst layer on top. Likewise, condensable particles will re-volatilize by the time they reach the catalyst. Neither case would prevent catalyst operation.

However, fine particulate might reach and deposit on the catalyst layer. Such fine particulate will be present in these exhaust streams.

Flare

As indicated, flares utilize continuous and highly concentrated CO and VOC streams. This would be technically infeasible for the PCS stream because it exhibits a low concentration of CO (<130 ppm) and a low VOC concentration. Utilizing a flare to control CO emissions is not technically feasible and will not be further analyzed.

Mold Vent Off Gas Autoignition

The MACT rule states that mold vent autoignition is occurring if a flame ignites more than 75% of the time during the pouring operation. It is FWNA's experience that this occurs more than 75% of the time in their process but to enhance the probability of auto-ignition, gas burner(s) will be situated along the conveyor downstream of the pouring station that will be oriented to ignite the vents on the mold assemblies in case they are not already burning. capture rate, which could alter the results of any BACT and the corresponding compliance demonstration.

5.9.3 Step 3: Ranking Remaining Control Technologies by Control Effectiveness

Mold vent off gas autoignition and incineration are the only technically feasible methods for CO control of PCS emissions. There is a major concern about operation of an RCO due to the possibility that the particulate and metals in the gas stream, in particular the silica particles will poison the catalyst. Regardless, an RCO is further evaluated for its cost effectiveness.

5.9.4 Step 4: Evaluate Most Effective Controls and Document Results

Please find the below discussion regarding the effective CO control technology by operation.

Electric Induction Furnaces
To evaluate the economic feasibility of installing an RCO or RTO downstream of the Melt Baghouse (CU01/ST02), the 2024 EPA cost estimating spreadsheets for an RCO and RTO were used to estimate the annualized costs. These cost spreadsheets estimate the equipment and operating costs for an oxidizer based on the exhaust flow rate from the processes and installing the necessary duct work to route the gases from the baghouse to the RCO/RTO.

Table 5-9 provides a summary of the cost effectiveness in controlling the CO emissions in this manner. Between the two different oxidizers the cost to control emissions from the Melt Baghouse (CU01/ST02) is estimated to be in the range of $42,000 to $82,000 per ton of pollutant controlled. As VOC could also be controlled by these technologies the cost effectiveness of controlling both emissions were evaluated and determined to be in the range of $37,000 to $71,000 per ton of pollutant controlled. Support for this evaluation is included in Appendix H.

Pouring, Cooling and Shakeout
To evaluate the economic feasibility of installing an RCO or RTO downstream of the Sand Plant Baghouse (CU06/ST07) and Core/Mold Baghouse (CU08/ST09) that control particulate emissions from pouring, cooling and shakeout, the 2024 EPA cost estimating spreadsheets for an RCO and RTO were used to estimate the annualized cost. These cost spreadsheets estimate the equipment and operating costs for an oxidizer based on the exhaust flow rate from the processes and installing the necessary duct work to route the gases from each baghouse to the RCO/RTO.

Table 5-10 and Table 5-11 provides a summary of the cost effectiveness in controlling the CO emissions in this manner.

Between the two different oxidizers the cost to control emissions from the Sand Plant Baghouse (CU06/ST07) is estimated to be in the range of $89,000 to $171,000 per ton of pollutant controlled. As VOC could also be controlled by these technologies the cost effectiveness of controlling both emissions were evaluated and determined to be in the range of $40,000 to $78,000 per ton of pollutant controlled. Support for this evaluation is included in Appendix I.

Between the two different oxidizers the cost to control emissions from the Core/Mold Baghouse (CU08/ST09) is estimated to be in the range of $8,000 to $16,000 per ton of pollutant controlled. As VOC could also be controlled by these technologies the cost effectiveness of controlling both emissions were evaluated and determined to be in the range of $5,100 to $10,000 per ton of pollutant controlled. Support for this evaluation is included in Appendix J.

5.9.5 Step 5: Select BACT

Table 5-8 lists the CO emission limits and controls that are currently in place for PCS operations in similar iron foundries which were taken from US EPA RACT/BACT/LAER Clearinghouse (RBLC) database as well as from a search of facility permits of other iron foundries producing similar products that the FWNA foundry will. Emission limits for CO from these operations tend to be consistent and range from 6 lb/ton to 10 lb/ton of molten metal poured. In most cases the shakeout emissions are separated out from the pouring and cooling emissions in order to

properly recover the sand. That is why the listing may show 1 lb/ton for shake out and 5 lb/ton for pouring and cooling, but the sum total of the PCS emissions is 6 lb/ton.

Table 5-12 provides the BACT limit and justification for each emission unit.

5.10 VOC BACT

As discussed in Section 1 and identified in Table 1-14, this permit application includes an increase in VOC emissions over the previous permit application. As shown in Table 1-14 this increase is attributed to the VOCs generated from the mixing of the two-part phenolic urethane resin with the sand prior to core-making as well as use of the core release agent. These emissions would be generated from the Acid Scrubber and associated stack (CU08/ST09). Additional VOC emissions from pouring and cooling would also be vented to CU08/ST09.

The increase in VOC emission is also attributed to the Sand Plant Baghouse (CU06/ST07) due to an increase in VOC from Shakeout (EU53). The previous BACT determination was based on an entry from Waupaca Foundry of 0.1 lb/ton. Waupaca Foundry has not been able to comply with this emission rate. As stated in Section 1, because of the production variables, it is technically more prudent to view PCS emissions in total rather than to attempt to identify VOC emissions from pouring, cooling and shakeout discretely.

To a lesser extent, an increase in VOC emissions above the previous application is identified for the Melt Baghouse (CU01) stack, ST01. Initially only VOCs from combustion were estimated. Performance testing indicates approximately ten (10) tons per year are being emitted from the melting operation.

In addition to the above and VOC emissions from the combustion of natural gas and diesel fuel from three emergency generators (EU72-EU74), VOC emissions occur from the following operations:

- In addition to shakeout, VOC emissions are released from the pouring and cooling due to the same reason that CO emissions exist, that is due to incomplete combustion of gases emitted from the mold during pouring, cooling, and shakeout process. These emissions are released via the Sand Plant Baghouse (CU06/ST07) and the Core/Mold Baghouse (CU08/ST09).
- VOC emission also occur at the finishing operation where the final parts are coated with zinc containing paint. This paint contains some VOC which is emitted from Paint Line #1 Booth Filter (CU17/ST16), Paint Line #2 Booth Filter (CU15/ST15B), and Paint Line #3 Booth Filter (CU14/ST15A).
- As stated above, there is also VOCs emitted from the core shop where the phenolic urethane resin is mixed with the sand and unreacted amine gas is exhausted through the sulfuric acid scrubber (CU07/ST08).
- Minor amounts of VOC emissions from the Core Wash Stations #1 and #2 (EU43, EU79) amount to approximately 0.27 tpy.
- Limited emissions of VOC occur related to the Rust Prohibitive Application (EU82) is the range of approximately 1.0 tpy.

The sources of VOC emissions in this application are identified in Table 5-13.

5.10.1 Foundry Operations

The following section assesses BACT for the typical foundry operations.

5.10.1.1 Step 1 – Identify All Control Technologies – Foundry Operations

Available control technologies with the practical potential for application to the emission unit are identified in Step 1. The application of demonstrated control technologies in other similar source categories to the emission unit of concern can also be considered. While identified technologies may be eliminated in subsequent steps in the analysis based on technical and economic infeasibility or environmental, energy, economic or other impacts, control technologies with potential application to the emission unit under review are identified in this step.

Under Step 1 of the BACT analysis, the following resources are typically consulted when identifying potential control technologies or work practices:

- Applicable NESHAP, NSPS and State Rules
- U.S. EPA's RBLC database;
- Determinations of BACT by regulatory agencies for other similar sources or air permits and permit files from federal or state agencies;
- Federal and/or state regulatory requirements;
- Engineering experience with similar control applications;
- Information provided by air pollution control equipment vendors with significant market share in the industry; and
- Review of literature from industrial technical or trade organizations.

NESHAP Review

As stated in Section 4, FWNA is subject to the Foundry Area Source Rule and is defined by the rule as a "new" source and a "large" foundry. As such, FWNA is subject to the no organic HAP/VOC requirements associated with the Foundry Area Source Rule other than the metallic scrap management program. Per 40 CFR §63.10885(a) the facility must operate by purchasing only metallic scrap that does not include "post-consumer automotive body scrap, postconsumer engine blocks, post-consumer oil filters, oily turnings, lead components, chlorinated plastics, or free liquids."

As an alternative to the above, the facility can operate according to written material specifications for the purchase and use of only iron and steel scrap that has been depleted (to the extent practicable) of organics and HAP metals in the charge materials used by the iron and steel foundry.

RBLC Review

A review of the RBLC was conducted in September 2021. The review assessed permits from the time period of January 2006 through November 2024. Table 5-14 includes VOC determinations contained in the RBLC.

The RBLC database included entries for melting, pouring, cooling, shakeout, coremaking and miscellaneous operations. Findings of the RBLC included the following:

- For electric induction melting operations, no add on controls were found.
- For pouring/mold cooling operations, no add on control devices were identified. Mold vent ignition was the only work practice standard identified.
- For shakeout operations, no add-on control devices were found. As discussed elsewhere in this document, compliance has not been demonstrated for RBLC entries with emission limits of 0.1 lb/ton.
- For PUCB core machines, acid scrubber for the control of catalyst emissions was identified in the RBLC along with an amine control efficiency of 88.9%.

Other VOC control devices are discussed below.

Other Air Pollution Control Alternatives

Control devices reduce VOC emissions by either recovering or destroying VOCs before they are discharged into the ambient air. Incineration, flares, and mold vent off gas ignition are all viable control technologies to reduce VOC emissions; however, they have been deemed technologically infeasible for the sand plant. The following additional methods can help to reduce VOC:

- Absorption
- Adsorption
- Condensation
- Incineration
- Biodegradation
- Good work practices

Absorption

Process gases are dissolved in a non-volatile liquid usually by contact in a scrubber which ensures a high surface area of contact between the gas and absorbing liquid (water or some other absorptive liquid in which the gases are soluble).

Adsorption

In adsorption, exhaust gases are routed across a matrix of adsorption solid media such as carbon. The carbon beds can be regenerated and the VOC-laden stream from regeneration reused, disposed of as waste, or incinerated.

Condensation

The exhaust gases are routed across a heat exchanger to drop the temperature of the gases to a value where it will condense out the VOC for collection and reuse or disposal.

Incineration

Incineration equipment increases the temperature of exhaust gas stream to the combustion temperature of VOC. There are three types of incineration systems: recuperative, regenerative, or catalytic. In a recuperative thermal oxidizer, the exhaust enters a combustion chamber and into a heat exchanger. The heat exchanger utilizes conduction to transfer heat to the waste gas through conduction. The exhaust gas can be used to preheat incoming waste gas and/or combustion air to offer fuel savings. A regenerative thermal oxidizer uses a direct contact heat exchanger to raise the exhaust

temperature. The heat exchanger is made up of a structured, high heat capacity media like a bed of porous ceramic packing. A catalytic oxidizer uses a precious metal-based catalyst bed and the oxygen in the gas stream to reduce combust the VOC emissions to CO2. The catalyst allows the combustion to occur at a lower temperature than it otherwise would have in a thermal incinerator.

Biofiltration

In biofiltration, exhaust gases are passed over a filter composed of biologically active material to destroy VOCs.

Good Work Practices

As identified in the RBLC the auto-ignition of mold vent gases is one work practice to reduce VOC emissions as well as the metallic scrap management requirements identified above.

5.10.1.2 Step 2: Eliminate Technically Infeasible Options

The following evaluates the technical feasibility of controlling emissions from foundry operations using the technologies identified above.

Absorption

Because of the complexity of the organic exhaust stream this option was determined to be infeasible for pouring, cooling and shakeout. An acid scrubber will be assumed for use as a means of reducing the amine gas catalyst from the phenolic urethane coremaking operation

Adsorption

Adsorption columns were determined to be technically infeasible methods of control as they typically operate at pollutant loading concentrations of 500 to 2000 ppm and flow rates on the magnitude of 5000 cfm. The high flow rates and low concentrations of this scenario would not allow the VOCs to be effectively adsorbed.

Condensers

Refrigerated condensers were also reviewed as a possible control technology for this scenario. There is no record of a system of this type ever being used in a foundry. Condensers require much greater pollutant loading concentrations than will occur at any typical foundry operations. Concentrations as high as 500 ppm will have removal efficiencies of less than 50%. Per these restrictions, a condenser would not be technically feasible.

Incineration

In the FWNA process, an add-on incinerator could only follow a baghouse due to high particulate content in the exhaust streams. Regenerative and catalytic systems can be rendered inoperable if the particulate residuals in the exhaust stream foul the catalyst bed of ceramic media packing of the RTO.

Even so placing an RCO downstream of a baghouse still may not protect the unit. Catalyst vendors state that certain compounds might poison a catalyst by reacting with the active sites on the catalyst to render it inactive. Typical elements that need to be considered are sulfur, phosphorus, silicon, and heavy metals. The latter two pollutants will be present in the exhaust. Vendors warn that even small concentrations of these elements can render a catalyst ineffective. The gas stream must be carefully characterized to make sure that poisons do not exist.

In particular vendors caution that particulate matter can mask or even poison a catalyst to render it ineffective. However, the size and physical state of the particles must be carefully considered; particles in the gas stream do not necessarily mean that RCO cannot be used. For example, coarse particles will be caught in the media bed and will not reach the catalyst layer on top. Likewise, condensable particles will re-volatilize by the time they reach the catalyst. Neither case would prevent catalyst operation.

However, fine particulate might reach and deposit on the catalyst layer. Such fine particulate will be present in the exhaust of these two streams.

Recuperative thermal oxidizers were reviewed to determine the technical feasibility of this control technology. The typical air flow rate for this type of control technology is from 500 to 50,000 standard cubic feet per minute (scfm). The air flow rates are well above the maximum of the typical range. The pollutant loading (concentration) for this technology should be approximately 1500 to 3000 ppmv to maintain appropriate temperatures required. This installation is well below these concentrations regardless of the emissions unit described. Due to these considerations described in USEPA's Air Pollution Control Technology Fact Sheet, recuperative thermal oxidizers were considered infeasible.

Flare

As indicated, flares utilize continuous and highly concentrated CO and VOC streams. This would be technically infeasible because of the low concentrations of CO and VOC in each exhaust.

Mold Vent Off Gas Autoignition

The MACT rule states that mold vent autoignition is occurring if a flame ignites more than 75% of the time during the pouring operation. It is FWNA's experience that this occurs more than 75% of the time in their process but to enhance the probability of auto-ignition, gas burner(s) will be situated along the conveyor downstream of the pouring station that will be oriented to ignite the vents on the mold assemblies in case they are not already burning. capture rate, which could alter the results of any BACT and the corresponding compliance demonstration.

5.10.1.3 Step 3: Ranking Remaining Control Technologies by Control Effectiveness

For melting, pouring, cooling and shakeout, provided the air volumes and concentrations, incineration would be the only control technology that would likely be feasible.

Regarding coremaking, the cores are produced in an enclosed automated press machine. The machine takes the properly weighed out core sand and mixes it with the appropriate amount of a two-part phenolic urethane resin and hardener. The care making process is referred to as the cold box method which involves passing the sand/binder core through an amine (typically dimethyl propylamine) gas which is a catalyst that quickly hardens the resin. The resins have a very low vapor pressure and the emissions from the core machine are primarily unreacted amine. The industry standard control device for this operation is a sulfuric acid scrubber, specifically designed to reduce the amine gas concentration for odor concerns.

5.10.1.4 Step 4: Evaluate Most Effective Controls and Document Results

This assessment is identical for one made for CO in the sections above. Tables 5-15 through 5-17 proved the cost effectiveness. In all cases, neither the RTO nor RCO control technology is cost effective. Due to the high particulate loading in the exhaust of these streams the potential control technologies other than incineration are not technically feasible.

Electric Induction Furnaces

To evaluate the economic feasibility of installing an RCO or RTO downstream of the Melt Baghouse (CU01/ST02), the 2024 EPA cost estimating spreadsheets for an RCO and RTO were used to estimate the annualized costs. These cost spreadsheets estimate the equipment and operating costs for an oxidizer based on the exhaust flow rate from the processes and installing the necessary duct work to route the gases from the baghouse to the RCO/RTO.

Table 5-15 provides a summary of the cost effectiveness in controlling the VOC emissions in this manner. Between the two different oxidizers the cost to control emissions from the Melt Baghouse (CU01/ST02) is estimated to be in the range of $277,000 to $527,972 per ton of pollutant controlled. As CO could also be controlled by these technologies the cost effectiveness of controlling both emissions were evaluated and determined to be in the range of $37,000 to $71,000 per ton of pollutant controlled. Support for this evaluation is included in Appendix K.

Pouring, Cooling and Shakeout

To evaluate the economic feasibility of installing an RCO or RTO downstream of the Sand Plant Baghouse (CU06/ST07) and Core/Mold Baghouse (CU08/ST09) that control particulate emissions from pouring, cooling and shakeout, the 2024 EPA cost estimating spreadsheets for an RCO and RTO were used to estimate the annualized cost. These cost spreadsheets estimate the equipment and operating costs for an oxidizer based on the exhaust flow rate from the processes and installing the necessary duct work to route the gases from each baghouse to the RCO/RTO.

Table 5-16 and Table 5-17 provides a summary of the cost effectiveness in controlling the VOC emissions in this manner.

Between the two different oxidizers the cost to control emissions from the Sand Plant Baghouse (CU06/ST07) is estimated to be in the range of $75,000 to $144,000 per ton of pollutant controlled. As VOC could also be controlled by these technologies the cost effectiveness of controlling both emissions were evaluated and determined to be in the range of $41,000 to $79,000 per ton of pollutant controlled. Support for this evaluation is included in Appendix L.

Between the two different oxidizers the cost to control emissions from the Core/Mold Baghouse (CU08/ST09) is estimated to be in the range of $14,000 to $27,000 per ton of pollutant controlled. As VOC could also be controlled by these technologies the cost effectiveness of controlling both emissions were evaluated and determined to be in the range of $5,100 to $10,000 per ton of pollutant controlled. Support for this evaluation is included in Appendix M.

Coremaking
To evaluate the economic feasibility of installing an RCO, regenerative thermal oxidizer or recuperative thermal oxidizer in place of or downstream of the Acid Scrubber (CU07/ST08), the 2024 EPA cost estimating spreadsheets were used to estimate the annualized costs. These cost spreadsheets estimate the equipment and operating costs for an oxidizer based on the exhaust flow rate from the processes and installing the necessary duct work to route the gases to the oxidizer.

Table 5-18 provides a summary of the cost effectiveness in controlling the VOC emissions in this manner. Between the three different oxidizers the cost to control emissions in place of or downstream of the Acid Scrubber (CU07/ST08) is estimated to be in the range of $20,000 to $38,000 per ton of pollutant controlled. Support for this evaluation is included in Appendix N.

5.10.1.5 Step 5: Selection of BACT

Table 5-14 provides BACT and permit listings for VOC from PCS operations at iron foundries similar to the FWNA foundry. For all three operations FWNA proposes a work practice for control of VOC from the PCS process by practicing and ensuring mold vent autoignition.

A work practice for the core shop is to maintain the pH of the sulfuric acid scrubber below a pH of 4.5 to ensure that amine is absorbed. As well as keeping any unused resin containers closed.

5.10.2 Coating Operations

FWNA has determined that it will not install a fourth paint line. Please refer to Appendix D for the emission calculations and Appendix G for the Safety Data Sheets (SDSs). As a result of the elimination of the fourth paint line with this application FWNA requests Alternative Operating Scenario #1 be identified within the Air Permit as the representative operating scenario.

Following the submission of the original air permit application and subsequent to the initial air permit application revision, FWNA and their contractors addressed a number of concerns regarding the appropriate BACT for the control of VOC emissions from the coating operations. This application incorporates that work.

5.10.2.1 Step 1 – Identify All Control Technologies

The finished product is coated with zinc particles applied in a spray coating operation using zinc containing paints. The potential VOC emissions from the three paint lines (EU68, EU69 and EU71) is 29.2 tpy.

Available control technologies with the practical potential for application to the emission unit are identified in Step 1. The application of demonstrated control technologies in other similar source categories to the emission unit of concern can also be considered. While identified technologies may be eliminated in subsequent steps in the analysis based on technical and economic infeasibility or environmental, energy, economic or other impacts, control technologies with potential application to the emission unit under review are identified in this step.

Under Step 1 of the BACT analysis, the following resources are typically consulted when identifying potential control technologies or work practices:

- Applicable NESHAP, NSPS and State Rules
- U.S. EPA's RBLC database;
- Determinations of BACT by regulatory agencies for other similar sources or air permits and permit files from federal or state agencies;
- Federal and/or state regulatory requirements;
- Engineering experience with similar control applications;
- Information provided by air pollution control equipment vendors with significant market share in the industry; and
- Review of literature from industrial technical or trade organizations.

NESHAP Review

As stated in Section 4, FWNA is an "area source" of hazardous air pollutants (HAPs) subject to the Foundry Area Source Rule as well as possible application of the Surface Coating Area Source Rule. Neither rule identify any rule applicability to FWNA operations.

RBLC Review

A review of the RBLC was conducted in November 2024. The review assessed permits from the time period of January 2006 through August 2024. The only VOC determination for the coating of iron castings contained in the RBLC was for the operation of FWNA.

Other VOC control devices are discussed below.

Other Air Pollution Control Alternatives

Control devices reduce VOC emissions by either recovering or destroying VOCs before they are discharged into the ambient air. Incineration, flares, and mold vent off gas ignition are all viable control technologies to reduce VOC emissions; however, they have been deemed technologically infeasible for the sand plant. The following additional methods can help to reduce VOC:

- Absorption
- Adsorption
- Condensation
- Incineration
- Biofiltration
- Good work practices

Absorption

Process gases are dissolved in a non-volatile liquid usually by contact in a scrubber which ensures a high surface area of contact between the gas and absorbing liquid (water or some other absorptive liquid in which the gases are soluble).

Adsorption

In adsorption, exhaust gases are routed across a matrix of adsorption solid media such as carbon. The carbon beds can be regenerated and the VOC-laden stream from regeneration reused, disposed of as waste, or incinerated.

Condensation

The exhaust gases are routed across a heat exchanger to drop the temperature of the gases to a value where it will condense out the VOC for collection and reuse or disposal.

Incineration

Incineration equipment increases the temperature of exhaust gas stream to the combustion temperature of VOC. There are three types of incineration systems: recuperative, regenerative, or catalytic. In a recuperative thermal oxidizer, the exhaust enters a combustion chamber and into a heat exchanger. The heat exchanger utilizes conduction to transfer heat to the waste gas through conduction. The exhaust gas can be used to preheat incoming waste gas and/or combustion air to offer fuel savings. A regenerative thermal oxidizer uses a direct contact heat exchanger to raise the exhaust temperature. The heat exchanger is made up of a structured, high heat capacity media like a bed of porous ceramic packing. A catalytic oxidizer uses a precious metal-based catalyst bed and the oxygen in the gas stream to reduce combust the VOC emissions to CO_2. The catalyst allows the combustion to occur at a lower temperature than it otherwise would have in a thermal incinerator.

Biofiltration

In biodegradation, exhaust gases are passed over a filter composed of biologically active material to destroy VOCs.

Good Work Practices

Possible work practices for coating operations includes the use of low VOC coatings and retaining VOC-containing coatings in closed containers when not in use.

5.10.2.2 Step 2: Eliminate Technically Infeasible Options

The following evaluates the technical feasibility of controlling emissions from foundry operations using the technologies identified above.

Absorption

This control method and associated technologies are considered infeasible because the VOC from the coating operation is not water soluble.

Adsorption

Adsorption is technically feasible for painting operations but typically adsorption is chosen as a viable control technique only when particulate in the exhaust stream being treated is minimal such as printing operations where only volatile vapors exist. Carbon adsorption has been used in the past for painting operations in the automotive industry where exhaust air flows are relatively small, and the VOC content is not large enough to warrant direct oxidation.

Following submittal of the original permit application but prior to the initial permit revision, Fritz Winter has contacted numerous vendors of pollution control devices to obtain quotes for installation of a carbon adsorption/ regeneration system. VOC air pollution control device vendors contacted did not offer onsite regeneration units or stated the relatively small amount of VOC emissions did not warrant a carbon regeneration system especially considering the absence of on-site process reuse or recovery.

Vendors encouraged the consideration of more cost-effective control technologies. The vendors stated that onsite regeneration of activated carbon is viable only when the quantities of VOC are much greater and when the recoverable material is intended for reuse in the process. Regardless, adsorption remains a technically feasible control option for the air permit application.

Condensation

Condensation will not be an effective control method because VOC concentrations from the paint booth would be too diluted to be condensed.

Biofiltration

Like adsorption, a biofilter will generate a solid waste requiring disposal and likely not be cost effective when compared to incineration/oxidation. It will be retained as a feasible alternative for evaluation.

Incineration

Incineration remains a technically feasible control option for this operation.

Good Work Practices

In order many operations especially where solvents are used or in coating operations the VOC containing materials can be managed properly to minimize evaporation from storage or if possible, obtain substitute low VOC containing materials.

5.10.2.3 Step 3: Ranking Remaining Control Technologies by Control Effectiveness

The remaining control technologies are ranked in the following order with regard to likely control effectiveness:

1. Incineration/Oxidation
2. Carbon Adsorption
3. Biofiltration
4. Good Work Practices

5.10.2.4 Step 4: Evaluate Most Effective Controls and Document Results

A cost effectiveness evaluation was made for the addition of an RTO, biofilter, and activated carbon adsorber in the previous application. Table 5-19 provides the results of that analysis for Phase 1 (as the fourth paint booth will not be installed). Cost effectiveness ranges from $23,000 to $48,000 per ton of VOC removed. Appendix O provides the text from the previous application along with the supporting documents.

Evaluation of the traditional EPA BACT cost effectiveness calculation spreadsheet for a carbon adsorption system with actual vendor quotes, indicated that the cost of a carbon adsorption system is higher than the EPA spreadsheet used for the original permit application would indicate. Evaluation of the traditional EPA BACT cost effectiveness calculation spreadsheet for an RTO with actual vendor quotes indicated that the cost of an RTO is lower than the EPA spreadsheets appear to indicate. The lowest cost of the two vendor quotes was then inserted into the cost effectiveness calculations and the new cost-effective results that are summarized in Table 5-19 and supported by Appendix O.

While the FWNA permit was the only application identified in the RBLC, during the 2017 air permit application revision, for BACT comparison purposes Fritz Winter reviewed permits from similar facilities that practiced surface coating of iron cast parts and identified three foundries. Their permits are provided in Appendix P, and the limits are summarized in Table 5-20. Neither of the three issued air permits require any kind of VOC treatment of emissions.

5.10.2.5 Step 5: Selection of BACT

The proposed BACT for the coating operation is good work practices by keeping unused paint and solvent containers covered at all times.

5.11 BACT for Utility Operations

Natural gas burners will be utilized in several places around the foundry. At the pouring stations they are used to ensure even heat of the refractory spout during the pouring operation, and at the refractory relining area where new ladles are being fabricated or old ladles are repaired with new refractory lining. New refractory linings must be heat treated and that is done using an open flame natural gas burner. Whenever natural gas is burned in the foundry it will be by open flame which ensures good combustion which minimizes both CO and VOC emissions. Since natural gas is used and not some other fossil fuel the amount of particulate being generated is also minimized.

BACT for natural gas burning is a work practice of burning it in an open flame following vendor recommendations to ensure complete combustion. The amount of particulate, CO and VOC generated from this combustion operation is assumed to be equal to or less than emissions listed in Section 1.4 of AP-42 for natural gas burning in boilers.

The FWNA foundry will have three diesel fired emergency generators to produce power for critical operations in the foundry in case of outage. These generators will meet the emission standards listed in NSPS Subpart IIII which has just been recently updated and is being proposed as BACT for that operation.

BACT for all the VOC emitting sources are summarized in Table 5-21.

Section 6
Air Quality Analysis

This section presents the Air Quality Analysis (Analysis) conducted to demonstrate that the FWNA facility will not cause or contribute to a violation of the National Ambient Air Quality Standards (NAAQS) or the Prevention of Significant Deterioration (PSD) Class I or Class II increments. The Analysis also confirms compliance with 401 KAR 63:020, which regulates potential hazardous matter and toxic air pollutants (TAPs), and evaluates the potential for secondary formation of ozone and fine particulate matter (PM2.5).

The PSD program is authorized under Part C of Title I of the Clean Air Act (42 U.S.C. §§7470–7492) and implemented through federal and state regulations, including 40 CFR Part 52.21 and 401 KAR 51:017. PSD requirements apply to areas designated as "attainment" or "unclassifiable" for all criteria pollutants. Simpson County, the location of the FWNA facility, currently holds such a designation and is therefore subject to PSD permitting requirements.

The FWNA facility qualifies as a PSD major source due to permitted emissions exceeding 100 tons per year (tpy) for carbon monoxide (CO) and volatile organic compounds (VOCs). Additionally, the facility has significant emission rates (SERs) for particulate matter (PM), PM_{10}, and $PM_{2.5}$.

Because the proposed project exceeds both the PSD major source thresholds for CO and VOC and the SERs for other regulated pollutants with established Significant Impact Levels (SILs), NAAQS, and PSD increment standards, a detailed air dispersion modeling analysis was performed in accordance with the Air Dispersion Modeling Protocol submitted to the Kentucky Division for Air Quality (KDAQ) and the subsequent KDAQ comments.

Initial screening results indicate exceedances of the PSD SILs for PM_{10} and $PM_{2.5}$, triggering the need for a cumulative impact analysis. The cumulative modeling results, presented in the following sections, demonstrate that the proposed project will not cause or contribute to exceedances of the NAAQS or PSD increment consumption thresholds.

All air dispersion modeling input files and additional supporting modeling information will be provided electronically in a separate submittal.

6.1 Modeling Methodology

Prior to conducting the Analysis an Air Dispersion Modeling Protocol document was submitted to KDAQ for review and comment. KDAQ comments were received on August 20, 2025. Those comments and the submitted protocol are provided in Appendix Q.

The air dispersion modeling addressed both the 2021 and 2025 comments received from KDAQ and USEPA Region 4 including the following:

1. The parallel version of AERMOD (AERMOD Breeze) was not utilized so an equivalent demonstration was not necessary.

2. The Analysis uses the most recent meteorological data for years 2020-2024 as provided by KDAQ.
3. As addressed below and in the appendices, all increment consuming sources provided by KDAQ were evaluated. See appendices, tables, and electronic files provided that support the application for validation.
4. A formal request for pre-construction monitoring waiver was submitted. The request is provided in Appendix R.
5. Justification for the use of existing ambient air monitors to provide background concentrations used in the model was provided in the 2025 protocol and addressed within this section.
6. An FLM/USFS Request for Determination form was prepared and submitted.
7. Air toxics analysis was prepared and completed by modeling the concentrations and comparing those to the Region 9, November 2024 Region Screening Level (RSL).
8. The NAAQS and PSD Increment modeling inventory was revised to reflect any changes to existing sources or additions to new sources in the area as addressed below, in the appendices or in the electronic files provided.
9. The final modeling report should document the basis for the emission rates used in the SIA modeling. Table 6-2 provides the emission rates with corresponding support for those emission rates provided in Appendix D. A
10. The Class I significant impact level (SIL) for the impact of modeled annual $PM_{2.5}$ emissions is compared to a concentration of 0.13 µg/m^3.
11. *A full 360 degree circumference of receptors were established at a distance of 50 km to compare modeling concentrations to the Class I SIL.*
12. *For comparing modeled concentrations to the $PM_{2.5}$ Class I SIL, project related secondary PM2.5 impacts (project related SO2 and NOx emissions) are considered.*
13. If necessary, the air dispersion modeled concentrations for the Class I annual $PM_{2.5}$ increment are compared to a concentration of 0.03 µg/m^3.
14. *The cumulative $PM_{2.5}$ increment consumption analysis, if required, should account for both the direct and the secondary component of $PM_{2.5}$ increment consumption from direct $PM_{2.5}$ emissions and precursor SO_2 and NO_X emissions from any nearby $PM_{2.5}$ increment sources*

A brief summary of the protocol is provided in the sections below:

6.1.1 Model Selection

The U.S. EPA's AERMOD dispersion model (version 24142) was used to conduct the air quality modeling analysis. AERMOD incorporates a state-of-the-science downwash algorithm and relies on AERMET, a meteorological preprocessor that applies current planetary boundary layer theory to derive dispersion coefficients from site-specific meteorological data.

The modeling was conducted using the regulatory default option, which includes:

- Stack-tip downwash to account for plume rise interference due to nearby structures; and
- Calm wind and missing data processing routines, ensuring proper averaging and continuity in modeled concentrations under low wind or incomplete meteorological conditions.

6.1.2 Meteorological Data

EPA modeling guidance allows the use of five years of off-site meteorological data or at least one year of on-site meteorological data. KDAQ provided meteorological data for the years 2020 through 2024.

6.1.3 Building Downwash

Emission sources were evaluated for potential building downwash effects based on their proximity to nearby structures. This assessment determines whether stack discharges may be entrained in turbulent wakes generated by wind flow around buildings. Such turbulence can significantly enhance plume dispersion and inhibit plume rise compared to unobstructed conditions.

To account for these effects, the modeling incorporated the Plume Rise Model Enhancements (PRIME) algorithm within AERMOD. Building dimensions were derived using the EPA's Building Profile Input Program (BPIP), which calculates direction-specific wake effects based on structure geometry.

Site-specific building and structure layouts were digitized and processed using BREEZE® BPIP software, which integrates the EPA-sanctioned BPIP-PRIME algorithms. This approach ensures accurate representation of dominant downwash structures and their influence on plume behavior across all wind directions.

6.1.4 Model Terrain

Terrain elevations for all modeled receptors, sources, and structures were derived from the U.S. Geological Survey (USGS) National Elevation Dataset (NED). These elevations were processed using AERMAP version 24142, the terrain preprocessor for AERMOD.

In addition to elevation, AERMOD requires a receptor-specific parameter known as the hill height scale, which supports its terrain-adjusted dispersion algorithms. AERMOD uses a critical dividing streamline approach to interpolate plume behavior between horizontal and terrain-following states. This method assumes that under certain meteorological conditions, a portion of the plume may ascend and pass over terrain features, while the remainder may be deflected and travel around them.

The hill height scale is calculated by AERMAP as a measure of the terrain feature within the modeling domain that would exert the greatest influence on plume behavior at each receptor. While it does not represent the critical dividing streamline height itself, it provides essential input for determining that height on an hourly basis using meteorological data.

Per Section 2.2.1 of the AERMOD User's Guide, the NED array boundary must encompass all terrain features that exceed a 10% elevation slope from any receptor to ensure accurate hill height scale calculations. The modeling domain was defined using the automated slope-based coverage feature in BREEZE® AERMOD, which ensures compliance with this requirement and optimizes terrain data handling. The terrain elevation for each modeled receptor, building, and source will be determined using the USGS National Elevation Dataset (NED).

6.1.5 Urban/Rural Determination

As with the initial construction modeling, the facility remains located in a predominantly rural area. Therefore, rural settings will be selected in AERMOD.

6.1.6 Receptor Grid Coordinate System

The Cartesian receptor grid used for the initial and subsequent construction demonstrations was retained for the Significant Impact Concentration (SMC) and Significant Impact Area (SIA) model runs. All receptors were placed using the UTM WGS84 coordinate system, with spacing designed to capture concentration gradients at varying distances from the facility:

- 100-meter spacing along the facility fenceline
- 100-meter spacing extending radially up to 4 kilometers from the facility center
- 500-meter spacing from 4 km to 10 km

The results of the SIA modeling established the extent of the SIA and informed the final receptor grid design. The 100-meter Cartesian grid surrounding the facility was used for NAAQS and PSD Increment modeling analyses.

Additional receptors were placed based on the locations of:

- Off-site sources
- Class I Areas, as applicable

This receptor configuration ensures adequate spatial resolution for capturing peak concentrations and regulatory thresholds across all modeling domains..

6.2 Modeled Emission Sources

The Significance Analysis evaluates the emission increases attributable solely to the proposed project. It excludes contributions from regional off-site sources and other existing facility sources, focusing strictly on project-related impacts.

In contrast, the National Ambient Air Quality Standards (NAAQS) Analysis incorporates both on-site and off-site sources of the pollutants of concern. This comprehensive approach ensures that cumulative impacts are assessed in accordance with U.S. EPA guidance.

All modeled emission sources at the FWNA facility were evaluated at their maximum hourly emission rates for each pollutant. This conservative approach ensures that worst-case impacts are captured during dispersion modeling.

The only emission sources excluded from the modeling were the emergency generators, which are permitted to operate up to 500 hours per year. Per EPA guidance, sources with limited, intermittent, and unpredictable operation—such as emergency generators—may be excluded from air quality modeling analyses when their contribution is deemed negligible and not representative of typical facility operations.

Off-site sources were obtained from both the Tennessee Department of Environmental Conservation (TDEC) and Kentucky Division for Air Quality (KDAQ) and evaluated as discussed below for inclusion in the NAAQS and PSD Increment modeling analysis.

6.3 Class II Significance Analysis

The Class II Significance Analysis was conducted to evaluate whether emission increases associated with the proposed project would result in significant ambient air impacts in the surrounding area. This analysis serves as a screening tool to determine the need for further cumulative modeling under PSD and NAAQS requirements.

The analysis included the following pollutants:

- Particulate Matter ≤10 microns (PM_{10})
- Particulate Matter ≤2.5 microns ($PM_{2.5}$)
- Carbon Monoxide (CO)

Significant impacts are defined as modeled concentrations exceeding the Significant Impact Levels (SILs), presented in Table 6-1.

6.3.1 Receptor Grid Coordinate System

The receptor grid used for the SIL evaluation was based on a Cartesian layout using the UTM WGS84 coordinate system, with the following spacing:

- 100-meter intervals from the facility center to 4,000 meters
- 500-meter intervals from 4,000 to 10,000 meters

Figures 6-1 and 6-2 illustrate the locations of buildings, receptors, and property boundaries. Figure 6-3 shows the receptor grid used for the SIL and SMC evaluations.

6.3.2 Modeling Approach and Results

All FWNA emissions units were included in the SIL and SMC analyses and evaluated at their maximum hourly emission rates for each pollutant as identified in Table 6-2 and supported by the emission calculations provided in Appendix D. The hourly emission rates can be verified by review of the hourly emission rate worksheet included in Appendix D and the corresponding emission unit and control device worksheets. All modeled stack parameters have been verified and are shown in Table 6-2.

Emergency generators were excluded from the analysis in accordance with EPA guidance, which allows exclusion of sources with limited, intermittent, and unpredictable operation (e.g., permitted for ≤500 hr/year).

Modeled results correspond to highest 1-hour (H1H) impacts over a five-year meteorological period. Results are summarized in Table 6-3, with graphical outputs provided in Figures 6-4 through 6-7.

Key findings:

- CO: Modeled concentrations did not exceed the SILs for either the 1-hour or 8-hour averaging periods, therefore no further modeling is required
- PM_{10}: Exceeded the 24-hour SIL, therefore cumulative modeling is required
- $PM_{2.5}$: Exceeded both 24-hour and annual SILs, therefore cumulative modeling is required

The maximum extent of SIL exceedance was identified from the $PM_{2.5}$ 24-hour modeling results, which showed ambient concentrations exceeding the SIL threshold at a distance of 2,680 meters from the facility. The other distances are identified in the figures and range from 490 to 2,110 meters. Information supporting the maximum distance to the receptor exceedance is provided in an Excel workbook provided in the modeling electronic files.

Accordingly, a 2,680-meter radius was established to define the Significant Impact Area (SIA) for all subsequent NAAQS and PSD Increment compliance demonstrations. This radius ensures that all receptors within the zone of significant impact are included in cumulative modeling analyses, consistent with EPA guidance and PSD permitting requirements.

6.4 Ambient Monitoring Requirements

The PSD Significance Analysis also serves to determine whether the applicant is subject to pre-construction ambient air monitoring requirements. This determination is based on a comparison of the maximum modeled impacts attributable to the proposed project against the Significant Monitoring Concentrations (SMC) defined in 40 CFR §52.21(i)(5)(i). Applicable SMC thresholds for PM_{10}, $PM_{2.5}$, and CO are presented in Table 6-1.

A pre-construction air quality analysis using continuous monitoring data may be required for pollutants subject to PSD review per 40 CFR 52.21(m). If either the predicted modeled impact from an emissions increase or the existing ambient concentration is less than the SMC, an applicant may be exempt from pre-construction ambient monitoring. The SMC value for $PM_{2.5}$ was vacated on January 22, 2013; however, EPA has responded to the vacatur by indicating that existing background monitors should be sufficient to fulfill the ambient monitoring requirements.

As shown in Table 6-4, the CO SMC was not exceeded, therefore, preconstruction monitoring is not required. The SMC was exceeded for the 24-hour PM_{10} and $PM_{2.5}$ and therefore preconstruction monitoring may be required. Below addresses the request that the preconstruction monitoring requirement be met with existing regional monitors.

6.4.1 Pre-Construction Monitoring Waiver Request

By letter dated July 14, 2025, FWNA requested a waiver from the 40 CFR 52.21(m) requirement to conduct pre-construction site-specific monitoring of ambient air for the purpose of establishing background concentrations for the permit application required air quality impact analysis. The request is provided in Appendix R. No response has been received at the time of the application.

6.4.2 Ambient Background Concentrations

As part of the KDAQ response to the 2021 waiver request FWNA was assigned the responsibilities of providing sufficient justification of a representative background monitoring location that fulfills the requirements of 401 KAR 51:017 and 40 CFR Part 51, Appendix W. This request was fulfilled in the submitted 2025 Air Dispersion Modeling Protocol but is also provided below.

The purpose of representative background monitoring concentrations is to account for concentrations that are not attributed to the source or site being evaluated and

not explicitly modeled in the air dispersion modeling analysis. The background concentration is to account for other emission sources such as natural sources, nearby sources other than the sources under consideration.

Per Section 8.3 of Appendix W, when determining background concentrations, the following should be considered:

- Background should not include the ambient impact of the project source or other nearby sources that are accounted for in the modeling;
- Ambient concentrations from natural sources in the area are typically accounted for in the background concentration.
- The dataset should be of sufficient completeness and follow appropriate data validation procedures.

$PM_{2.5}$ Background Concentration Determination

The nearest $PM_{2.5}$ monitor is located at 226 Sunset Street, Smiths Grove, Bowling Green, Kentucky (Smiths Grove - AQS Site ID 21-227-0009). This monitor was used in the previous permit applications. The monitoring location is classified by USEPA as being "Residential," but the location is near a heavily populated and traveled area. The resulting background concentrations from the Bowing Green monitor is provided in Table 6-5.

PM_{10} Background Concentration Determination

The PM_{10} background monitoring location used for the Franklin, Kentucky site in the 2016 permit application was from the Nashville Monitor (AQS ID: 47-037-0024) active 2000 through 2016 located at 56th Avenue and Louisiana Streets in Nashville, TN. The 2022 permit application used the nearest PM_{10} monitor located at 105 South 17th Street, Nashville, TN (Davidson County) at the Lockland School (Lockeland Monitor – AQS Site ID 47-037-223).

The Lockeland Monitor was concerning for several reasons. It is labeled "Industrial," which often suggests influence by nearby point or area sources. Franklin's terrain and zoning is more rural-industrial mix — not urban-core like East Nashville.

To identify a better alternative that aligns with EPA guidance, an evaluation of the Lockeland Monitor and other proximal monitors is provided in Table 6-6. Preferably the representative wind orientation would be upwind or crosswind, similar land use to the modeling site, high data completeness, ideally be rural.

Evansville, IN monitoring location better meets the established criteria due to the following:

- Crosswind orientation that minimizes source influence while reflecting regional background conditions
- Land use compatibility including agricultural and light industrial areas on the county periphery, similar to the FWNA facility
- Terrain and elevation reasonably consistent with Simpson County (~116 m vs ~198 m)
- High data completeness (≥98%) across multiple years ensuring robust background estimation

- Monitor classified as urban, but with peripheral conditions aligning more closely to rural Simpson County

To develop background concentrations, monitoring values were downloaded from EPA AirData Air Quality Monitors database for the Evansville, Indiana site. Using calendar years 2022-2024, the resulting background concentration for the 24-hour PM_{10} standard is 60 µg/m^3 (significantly higher than the 35.67 µg/m^3 used in the previous application) as provided in Table 6-7.

Both the Evansville and Bowling Green monitors meet the above requirements and provide a conservative background concentration for the FWNA location as both areas are urban locations.

6.5 Regional Inventory Data

As identified above, the SIL was exceeded for the PM_{10} 24-hour standard, $PM_{2.5}$ 24-hour standard and the $PM_{2.5}$ annual standard. As such, it was necessary to develop regional inventory data for Class II modeling for each of these standards. Because of the facilities proximity to Tennessee, in addition to KDAQ, Tennessee Department of Environmental Conservation (TDEC) provided emission inventories of potential sources that can impact the air quality within the impact area.

The regional modeling inventory information was compiled by determining all sources from the KDAQ and TDEC inventories located within a 50 km radius of the FWNA facility. As provided for in the air dispersion modeling protocol, EPA's 20D rule was used as a screening technique to allow the elimination of any sources where emissions (in tpy) are less than 20 times the distance from the source. Prior to applying the "20D Rule" various emission sources at a single facility were combined such that they were not eliminated. The workbooks in electronic format showing the reduction in facilities are provided in the Electronic Air Dispersion Modeling Files. Following the evaluation and removal of the portable sources and the shutdown of the Brite Metal facility, only the RKW North America facility remained. Following the review of the RKW North America facility Air Permit, Tables 6-8 through 6-11 provide the emission rates and stack parameters for RKW North America used in the PM_{10} and $PM_{2.5}$ NAAQS and PSD Increment modeling analysis. The RKW North America Air Permit is provided in Appendix S.

6.6 Cumulative Modeling Analysis

A Cumulative Analysis modeling was required for PM_{10} and $PM_{2.5}$ based on the screening model results discussed above; therefore, modeling was performed to demonstrate compliance with the NAAQS standards and PSD Increment values identified in Table 6-1.

6.6.1 National Ambient Air Quality Standard Modeling Results

To demonstrate compliance with the $PM_{2.5}$ annual standard, each year of meteorological data was modeled and the highest value from each of the five models was compared to the annual standard. To demonstrate compliance with the $PM_{2.5}$ and PM_{10} 24-hour standards the models were run with all five years of meteorological data. The NAAQS modeling includes all FWNA emission units at their maximum hourly emission rates identified in Table 6-2, as well as the RKW North America facility at the emission rates shown in Tables 6-8 and 6-9. The refined PM_{10} and $PM_{2.5}$ modeling (NAAQS and PSD Increment) included only those receptors that

were within the largest calculated SIA for the respective averaging time (as determined above the SIA is a radius of 2,680 m from the facility).

Figure 6-8 identifies the receptor locations for the refined modeling at 100-meter spacing from the facility to 2,680 meters in each direction. Source included in the modeling were the FWNA sources along with the applicable off-site sources.

Table 6-10 presents the summary of results for PM_{10} 24-hour and $PM_{2.5}$ Annual model runs and demonstrates compliance with their respective NAAQS standards.

6.6.2 PSD PM_{10} and $PM_{2.5}$ Increment Modeling Results

In addition to NAAQS modeling, the modeling also must demonstrate compliance with the PSD increment. The PSD increment, which can only be assessed through modeling, is the means by which the PSD rules prevent air quality from being deteriorate any more than that threshold.

The analysis starts with a baseline date and any emission sources added after that baseline date are included in the increment model runs. For major sources of PM_{10} the baseline date started in 1987 for $PM_{2.5}$ it was 2010. For minor sources, the baseline date is established by the initial complete PSD application submitted in the Baseline Impact Area. This permit application was submitted on July 13, 2016, by FWNA. Therefore, the final off-site source list must include any source. installed or modified after that date. RKW North America EU06 and EU09 printing lines were installed after the July 13, 2016 data and are included in the PSD Increment Modeling at the emission rates and stack parameters shown in Table 6-11 and 6-12.

Table 6-13 compares the highest second high modeling 24-hour result for the each of the five years of meteorological data to the increment limit for PM_{10} and $PM_{2.5}$ while the highest high modeling results for each of the five years of meteorological data is used for the corresponding annual increment. As shown in table, all impacts were less than the standard.

6.7 Class II Modeled Emission Rates for Precursors (MERPs) Analysis

KDAQ released a document entitled “Guidance on the Use of EPA’s Modeled Emission Rates for Precursors (MERPs) for Secondary Pollutant Formation in Kentucky PSD Projects” on November 13, 2024 following review of EPA’s April 30, 2024 memorandum clarifying information on the development Application of the . ’s Modeled Emission Rates for Precursors (MERPS) for Secondary Pollutant Formation in Kentucky.” Following release of this document, on April 30, 2019, USEPA issued an update to their guidance entitled “Guidance on the Development of Modeled Emission Rates for Precursors (MERPs) as a Tier 1 Demonstration Tool for Ozone and $PM_{2.5}$ under the PSD Permitting Program.”

When modeled design concentrations are less than the applicable SIL, further analyses (NAAQS and PSD Increment) are not required for that pollutant-averaging period. If modeled impacts are greater than the SIL, a full NAAQS and PSD Increment analysis is required for that pollutant and averaging period to demonstrate that the facility neither causes nor contributes to any exceedances.

In accordance with the revised and updated 40 CFR 51, Appendix W, precursor emission impacts to ozone and $PM_{2.5}$ (secondary $PM_{2.5}$) must be considered as part of the modeling analysis. The precursors to ground-level ozone formation are VOC and NOX, and the precursor emissions for secondary $PM_{2.5}$ formation are NO_X and SO_2.

Elevated ground-level ozone concentrations are the result of photochemical reactions among various chemical species. These reactions are more likely to occur under certain ambient conditions (e.g., high ground-level temperatures, light winds, and sunny conditions). The chemical species that contribute to ozone formation, referred to as ozone precursors, include NO_X and VOC emissions from both anthropogenic (e.g., mobile, and stationary sources) and natural sources (e.g., vegetation). Pursuant to 40 CFR 52.21, ambient ozone monitoring is not required unless a project's emissions increase is greater than one hundred tpy of VOC or NOX.

6.7.1 MERPs Ozone and $PM_{2.5}$ Source Impact Analysis

The MERPs Source Impact Analysis assesses air quality impacts from the proposed new source only. The projected air quality impact from the source is calculated and compared to the applicable SIL to determine if the Tier 1 demonstration is satisfied or if a cumulative impact analysis is necessary.

Ozone Source Impact Analysis

As Outlined in Table 3 of the KDAQ 2024 guidance, the default MERP values (tpy) for KDAQ applications are 170 tpy NOx and 2,939 tpy VOC for the 8-hour ozone standard.

For the Source Impact Analysis, the guidance indicates the following equation [Guidance Eq. 2] should be used for the initial analysis and nothing further is required if this standard is met:

$$\frac{NOx\ Emission\ Rate}{NOx\ MERP} + \frac{VOC\ Emission\ Rate}{VOC\ MERP} < 1$$

Solving for the above equation provides the following result:

$$\frac{13.24}{170} + \frac{223.47}{2939} < 1$$

$$0.08 + 0.08 < 1$$

$$0.16 < 1$$

As the predicted ozone value is less than the threshold value of 1, the predicted impact of the projects is less than the ozone SIL (1 ppb). Therefore, there are no adverse impacts associated with precursor emissions for ozone, and a cumulative ozone analysis is not required.

$PM_{2.5}$ Source Impact Analysis

As outlined in Table 3 of the KDAQ 2024 guidance, the default MERP values (tpy) for KDAQ applications are 2,922 tpy NO_X and 1,433 tpy SO_2 for daily $PM_{2.5}$ and 5,476 tpy NO_X and 6,321 tpy SO_2 for annual $PM_{2.5}$.

The KDAQ 2024 guidance provides the following equation [Guidance Eq. 3] for determining if a cumulative analysis is necessary when the project emissions exceed the $PM_{2.5}$ significant emission rate (SER) of ten (10) tpy:

$$\frac{Max\ PM2.5\ ModeledConcentration}{PM2.5\ SIL} + \frac{SO2\ Emission\ Rate}{SO2\ MERP} + \frac{NOx\ Emission\ Rate}{NOx\ MERP} < 1$$

24-hour $PM_{2.5}$ Discrete Analysis:

Substituting the values for the 24-hour $PM_{2.5}$ standard:

$$\frac{10.50}{1.2} + \frac{0.88}{1{,}433} + \frac{13.24}{2{,}922} > 1$$

$$8.75 + 0.0006 + 0.0045 > 1$$

$$8.76 > 1$$

Annual $PM_{2.5}$ Discrete Analysis:

Substituting the values for the Annual $PM_{2.5}$ standard:

$$\frac{1.86}{0.13} + \frac{0.88}{6{,}321} + \frac{13.24}{5{,}476} > 1$$

$$14.31 + 0.0001 + 0.0024 > 1$$

$$14.31 > 1$$

As the resultant 24-hour and Annual PM2.5 values exceed one (1), a cumulative analysis is required.

6.7.2 MERPs $PM_{2.5}$ Cumulative Analysis

Because both the 24-hour and Annual $PM_{2.5}$ discrete analysis resulted in values greater than 1 a cumulative analysis must be conducted. Per the 2024 Guidance, the $PM_{2.5}$ cumulative analysis uses the following equation [Guidance Eq. 5]:

$$PM2.5\ BG + PM2.5\ DV + \left(\frac{SO2\ Emission\ Rate}{SO2\ MERP} + \frac{NOx\ Emission\ Rate}{NOx\ MERP}\right) x\ PM2.5\ SIL \leq PM2.5\ NAAQS$$

24-hour $PM_{2.5}$ Cumulative Analysis:

$$17.90 + 6.81 + \left(\frac{0.88}{1{,}433} + \frac{13.24}{2{,}922}\right) x\ 1.2 \leq 35$$

$$17.90 + 6.81 + (0.0006 + 0.0045)\ x\ 1.2\ \leq 35$$

$$17.90 + 6.81 + (0.0006 + 0.0045)\ x\ 1.2\ \leq 35$$

$$24.72\ \leq 35$$

Annual $PM_{2.5}$ Cumulative Analysis:

$$6.90 + 1.86 + \left(\frac{0.88}{6{,}321} + \frac{13.04}{5476}\right)\ x\ 0.13\ \leq 9$$

$$6.90 + 1.86 + (0.0001 + 0.002)x\ 0.13\ \leq 9$$

$$8.76\ \leq 9$$

Both 24-hour and annual PM2.5 concentrations met the requirements of the cumulative analysis.

6.8 Class I Significance Analysis

Class I areas are federally protected areas for which more stringent air quality standards apply to protect unique natural, cultural, recreational, and/or historic values. The current Federal Land Manager (FLM) policies, as outlined in the FLAG document (2010 Federal Land Air Guidance) state that any Class I areas within 300 km of the proposed source as well as any other Class I areas that may be potentially affected should be identified and evaluated for potential air quality impacts on those Class I areas.

Table 6-14 lists these Class I areas, their location coordinates, their distance from the proposed site. each location. The below sections evaluate the potential impacts to those Class 1 area locations.

6.8.1 Class I Area Screening (Q/D) Analysis

There are five Class I areas within 300 km of the proposed FWNA foundry, the closest area is Mammoth Cave located approximately 51 km northeast of the proposed site.

To demonstrate the project will have no significant impacts on Class I air quality relative value (AQRV) including visibility the Federal Land Managers' Air Quality Related Values Work Group (FLAG) Phase I Report provides a Q/D screening criteria if the Class I Area is more than 50 km away. The Q/D screening criteria indicates that if the total sulfur dioxide (SO_2), nitrogen oxides (NO_x), PM_{10}, and sulfuric acid mist (H_2SO) annual emissions (in tons per year, based on 24-hour maximum allowable emissions), divided by the distance (in km) from the Class 1 area is less than 10, then the project is assumed to have no impact on AQRVs.

As shown in Table 3-2, the total annual visibility affecting emissions from the FWNA facility is 42.6 tpy (28.48 tpy PM_{10} + 0.88 SO_2 + 13.24 tpy NO_x). As the nearest Class I area is fifty-one (51) kilometers away, the resulting Q/D is 0.84, which is well below the threshold of 10.

6.8.2 Class I Significant Impact Evaluation

To evaluate the maximum potential impact of the FWNA facility on the Class I areas, AERMOD was used to determine concentrations at the boundary of the model to show the concentrations are less than the Class I SIL values identified in Table 6-15.

To accomplish this, receptors were placed at a radius of 50 km from the facility spaced 1/10 of 1° degree between receptors. The resulting receptor network is shown in Figure 6.9. To conduct the analysis the 2020 – 2024 meteorological data was used. The highest 24-hour and annual PM_{10} and $PM_{2.5}$ concentrations are 0.0075 and 0.1550 µg/m^3, respectively. As shown in Table 6-15 these values represent concentrations that are between 25 to 57% of the Class I SIL values.

6.8.3 Class I MERPs Tier 1 Demonstration

In accordance with the U.S. EPA's April 30, 2024 memorandum titled Clarification on the Development of Modeled Emission Rates for Precursors (MERPs) as a Tier 1 Demonstration Tool for Ozone and $PM_{2.5}$ under the PSD Permitting Program, the applicant has utilized the MERPs framework to assess secondary $PM_{2.5}$ impacts associated with precursor emissions. This guidance clarifies the appropriate use of MERPs in light of updated Significant Impact Levels (SILs) and the strengthened annual $PM_{2.5}$ National Ambient Air Quality Standard (NAAQS). Rather than relying on fixed emission rate thresholds, the revised approach emphasizes a normalized air quality impact comparison against critical SIL values. This method provides a technically sound and policy-consistent pathway for demonstrating that precursor emissions—such as NO_x and SO_2—do not cause or contribute to $PM_{2.5}$ concentrations exceeding the applicable SILs, thereby supporting exemption from cumulative modeling requirements under Tier 1 analysis.

The Franklin, Kentucky facility is located approximately 51 miles northeast of Mammoth Cave National Park, the nearest Class I area. AERMOD modeling of primary $PM_{2.5}$ emissions indicates maximum predicted concentrations of 0.0075 µg/m³ (annual) and 0.1550 µg/m³ (24-hour) at the AERMOD 50 km boundary. These values represent 57% and 25% of the respective Class I Significant Impact Levels (SILs), which are 0.03 µg/m³ (annual) and 0.27 µg/m³ (24-hour).

As clarified in the EPA's April 30, 2024 memorandum, modeled concentrations below the SIL thresholds are considered not to cause or contribute to a violation of the NAAQS or PSD increments, satisfying Tier 1 demonstration requirements for direct $PM_{2.5}$ emissions.
To evaluate secondary $PM_{2.5}$ impacts from precursor emissions (NO_x and SO_2), the applicant should apply the MERPs framework as outlined in the same memo. This approach normalizes precursor emissions against modeled air quality impacts, allowing for a quantitative comparison to SIL values. The following section presents the MERPs-based analysis for secondary $PM_{2.5}$ formation at Mammoth Cave.

To assess secondary $PM_{2.5}$ formation from precursor emissions, the approach beginning at the bottom of page 4 of the Attachment to the April 30, 2024, EPA Memo "Clarification on the Development of the Modeled Emission Rates for Precursors (MERPs) as a Tier 1 Demonstration Tool for Ozone and PM2.5 under the PSD Permitting Program" was used.

Specifically, page 6 of the memo states "the initial screening step would be to select one or more of the hypothetical sources modeled as part of the illustrative assessment providing in this document that are found to be similar to the project source. The modeled maximum secondary

$PM_{2.5}$ impacts at or greater than 50 km would be used in combination with the primary $PM_{2.5}$ impacts estimated using AERMOD at 50km downwind of the source for comparison to the EPA recommended $PM_{2.5}$ Class I SIL value. In addition, if the result of the initial screening step show an exceedance of the $PM_{2.5}$ Class I SIL value a second more refined screening step would involve selecting the highest modeled secondary PM2.5 impact at or less than the downwind distance of the Class I area relative to the project source.

From the Attachment's Figure 4-2, the 24-hour and Annual secondary impacts 50 km from a 500 tpy surface level source of NO_X emissions is 0.026 and 0.002 ug/m3, respectively. Following the Attachment's methodology yields the following results:

For the 24-hour Secondary $PM_{2.5}$ impact associated with NO_X:

$$13.25\ tpy\ NOx\ x\ \frac{1}{500} tpy\ NOX\ x\ 0.026 \frac{ug}{m3} = 0.0007 \frac{ug}{m3}$$

For the Annual Secondary PM2.5 impact associated with NO_X:

$$13.25\ tpy\ NOx\ x\ \frac{1}{500} tpy\ NOX\ x\ 0.002 \frac{ug}{m3} = 0.0001 \frac{ug}{m3}$$

Regarding the 24-hour secondary $PM_{2.5}$ impact associated with sulfur dioxide, insufficient information was provided in the above identified memo and Attachment, therefore a graph was developed of secondary $PM_{2.5}$ emissions associated with the emissions of SO_2 at various distances. The graph is included as Figure 6-13. The graph is used to generate the following estimates of 24-hour and Annual secondary $PM_{2.5}$ concentrations associated with 0.88 tpy SO_2 at a distance of 51 km.

Calculation:

1. Source scaling: 0.88 tpy ÷ 500 tpy = 0.00176 (scaling factor)
2. At 51 km from the elevated source chart:
    - Daily maximum ≈ 0.15 μg/m³ (for 500 tpy source)
3. Scaled concentration: 0.15 μg/m³ × 0.00176 = 0.00026 μg/m³

Key Considerations at 51 km:

- High conversion efficiency: 80% of SO2 converts to sulfate at this distance
- Molecular weight factor: $SO4^{2-}$/SO2 = 1.5
- Significant dispersion: Concentrations are much lower due to atmospheric mixing
- Chemical transformation time: ~2-4 hours transport time allows substantial secondary formation

Regulatory Context:

- This concentration (0.00026 μg/m³) is well below:
    - Class I PSD increment (24-hour): 0.27 μg/m³
    - Class II PSD increment (24-hour): 1.2 μg/m³

- PM2.5 NAAQS (24-hour): 35 µg/m³

The approximate concentration of 0.0003 µg/m³ for the 24-hour maximum secondary $PM_{2.5}$ sulfate concentration at 51 km reflects both the small source size (0.88 tpy) and the substantial dispersion that occurs over 51 km. Even accounting for modeling uncertainties, this source would have negligible impact on $PM_{2.5}$ concentrations at that distance.

To estimate the annual average secondary $PM_{2.5}$ concentration from 0.88 tpy SO2 at 51 km the calculation is as follows:

1. Source scaling: 0.88 tpy ÷ 500 tpy = 0.00176 (scaling factor)
2. At 51 km from the elevated source chart:
    - Annual average ≈ 0.009 µg/m³ (for 500 tpy source)
3. Scaled concentration: 0.009 µg/m³ × 0.00176 = 0.000016 µg/m³

Key Factors at 51 km:

- High SO_2 to sulfate conversion: ~80% conversion efficiency over the transport time
- Atmospheric mixing: Annual average accounts for varying wind directions and stability classes
- Long-range transport: Plume is well-mixed vertically and horizontally
- Seasonal variations: Included in annual averaging

Regulatory Comparison:

- This concentration (0.000016 µg/m³) is extremely small compared to:
    - Class I PSD increment (annual): 0.03 µg/m³
    - Class II PSD increment (annual): 0.13 µg/m³
    - PM2.5 NAAQS (annual): 9.0 µg/m³

Similar to the above the resulting concentration of approximately 0.00002 µg/m³ for the annual average secondary $PM_{2.5}$ sulfate concentration at 51 km is due to both the limited emissions and the 51 km distance.

Results of the PM_{10} and $PM_{2.5}$ Class I SIL Analysis includes secondary $PM_{2.5}$ impacts is provided in Table 6-15.

6.9 Toxics Modeling

The project includes emissions of certain compounds that have a Regional Screening Level (RSL) value identified in EPA Region IX RSL tables. To demonstrate FWNA will comply with 401 KAR 63:020 that regulates potential hazardous matter or toxics substances (i.e., toxic air pollutants – TAPs) and in order to evaluate whether these toxic compounds are in sufficient concentration that they could present a health hazard, air dispersion modeling is conducted per KDAQ's request.

The same meteorological data and stack conditions described elsewhere are used to determine maximum annual ground level concentrations of each TAP. The maximum concentration of the receptors of concern are compared to the concentrations listed as having a significant health threat in

EPA Region IX "Regional Screening Level (RSL) Resident Ambient Air Table (TR=1E-6, HQ=1) November 2024".

Similar to the initial application Figure 6-11 provides an area map and on this map, we located model receptors at location where individuals may be present for an extended period (residences, work areas etc.). This sensitive receptor set was then input to the model and using the same meteorological data and stack conditions described in this section, AERMOD was used to calculate the maximum annual ground level concentrations of each of the toxic compounds at each receptor.

The maximum concentration of all the receptors was compared to the RSL. Table 6-16 provides the results of this modeling that demonstrates the maximum concentration found in our modeling are below the RSL listed values. The modeling files are provided electronically.

Section 7
Other Impact Analysis

PSD regulations require that additional impacts be considered as part of a PSD permit action. These include a growth analysis and a soil and vegetation analysis. The effect of the proposed project's emissions on local soils and vegetation is addressed through comparison of modeled impacts to secondary NAAQS and other relevant screening criteria that have been developed by the U.S. EPA to provide protection for public welfare, including protection against decreased visibility, damage to animals, crops, vegetation, and buildings.

An economic growth analysis is intended to assess the amount of new growth that is likely to occur in support of the new project and to estimate emissions resulting from associated growth. Associated growth relates to any residential and commercial/industrial growth that may result from the construction of the proposed project. Residential growth depends on the number of new employees and the availability of housing in the area, while associated commercial and industrial growth consists of new sources providing services to the new employees and the facility.

This AIA assesses the environmental impact on soils, vegetation, and when necessary, the visibility caused by the increase in emissions following the projects and any associated impact resulting from associated industrial, commercial, and residential growth. A separate task to assess the ambient air quality following the changes is completed and resulted in the demonstration that compliance with the National Ambient Air Quality Standards (NAAQS) and PSD Increments is provided in Section 6 of this document.

7.1 Ambient Air Quality Analysis

The ambient air quality analysis projects the air quality that will exist in the area of the proposed source during construction and after the plant begins operation.

As part of the PSD permit application, air dispersion modeling is conducted to demonstrate compliance with the National Ambient Air Quality Standards (NAAQS) and PSD Increments for significant pollutants of concern. The modeling included the foundry and machining emissions, nearby emission sources that could potentially impact the proposed location, and background concentrations to predict the resultant maximum ambient air quality impacts around the constructed facility. The results of the air dispersion modeling showed compliance with all applicable standards and/or requirements.

7.2 Class I Visibility

Visibility can be affected by plume impairment or regional haze. Plume impairment results when there is a contrast or color difference between the plume and a viewed background (the sky or a terrain feature). Plume impairment is generally only of concern when the Class I area is near the proposed source (i.e., less than 50 km). As the Mammoth Cave National Park is just over 50 km, the possibility of plume impairment will be assumed.

To address the above, the EPA New Source Review Workshop Manual recommends that a visibility analysis be conducted. There are three levels for the visibility analysis: Level 1, Level 2, and Level 3. A

Level 1 analysis is the most conservative and if the visibility screening criteria is not exceeded no further analysis is required.

VISCREEN was used to assess possible impacts on visibility due to the proposed project. VISCREEN is an EPA-approved model that assesses the visibility of plumes of emission sources from a vantage within the nearest Class I area. VISCREEN uses a very conservative approach to assess visibility impacts as it uses the "worse-case" meteorological values for wind speed and stability class.

VISCREEN requires inputs of emissions of particulate matter and nitrogen oxides (primary NO_2, primary SO_4 and soot are also considered if present). Table 3-2 annual PM and NOx emissions rates of 28.48 tpy and 13.24 tpy, respectively were used are shown in Table 7-1. Detailed emission calculations for total PM and NO_x can be found in tables in Appendix D.

The nearest Class I area is Mammoth Caves National Park located north-northeast from FWNA with a nearest boundary of 51 km and the farthest boundary of the wilderness area is estimated at 62 km. The observer distance was chosen at the nearest Class I area boundary. The analysis used EPA-recommended default parameters, including a background visual range of 180 kilometers, high terrain contrast, and conservative plume characteristics.

The VISCREEN Summary Report is provided in Appendix T and includes the distance and the observer angles, theta, azi, and alpha, present conservative line of sight values that maximize the light-scattering properties of the emissions from the proposed source. Results are given in the "Plume" columns of both the Delta-E and Contrast parameters. The criteria are also provided for comparison. The Delta-E is the color difference parameter that specifies the perceived changes of color and brightness. This is the primary basis for determining the perceptibility of plume visual impacts. The criteria used by VISCREEN for Delta-E is 2.0. The threshold value of perceptibility has been traditionally 1.0 for Delta-E and 0.02 for contrast. The Contrast column is the green contrast (0.55 km) which has a criteria value of 0.05.

Results showed that within the Class I area, the maximum color difference (ΔE) values were 0.3 against a sky background and 0.8 against terrain—both well below the EPA screening threshold of 2.0, indicating no perceptible plume impact. However, outside the Class I area, ΔE values reached 5.3 (sky) and 6.4 (terrain) at a receptor located 1 kilometer from the source, exceeding the screening criteria and suggesting potential plume visibility. Based on these findings, the project passes Level 1 screening for impacts within Mammoth Cave National Park.

7.3 Secondary Impacts on Soil and Vegetation

No impacts are expected on soils or vegetation in either Simpson or the surrounding counties. Ambient concentrations of air pollutants that typically impact vegetation such as ozone, NO_x, and SO_2 are not significantly increased by the proposed project. The primary pollutant from the facility is carbon monoxide. NO_x and SO_2 emission increase were small enough that federal regulations do not require an ambient impact analysis. A qualitative assessment of the ozone impacts due to the direct emissions of VOC and NO_x was completed and has determined that it is very unlikely that secondary formation of ozone from VOC or NOx emissions, attributable to the project, will have a significant impact on the ozone levels in the area.

Conversion of nitrogen oxides (NO_x) and VOC emissions to tropospheric ozone is not instantaneous, but occurs over time, with the rate of conversion dependent upon weather conditions. The rate of ozone

production can be limited by either VOCs or NO_2. In general, ozone formation using these two precursors is reliant upon the relative sources of hydroxide (OH) and NO_x. In urban areas with a high population concentration, ozone is often VOC-limited. Ozone is generally NO_x-limited in rural areas and downwind suburban areas" (EPA-452/R-08-003 March 2008). Further, ozone formation is recognized as a regional and long-range transport issue. Therefore, it is very unlikely that secondary formation of ozone from VOC emissions attributable to the project will have a significant impact on the ozone levels in the area.

Particulate matter emissions from melting, pouring, cooling, shotblast, and grinding consist largely of oxides of iron. Particulate emissions from the mold and core production and shakeout consist mostly of sand, clay, and iron oxides. None of the particulate emissions are expected to have adverse impacts on soils or vegetation. Sand, clay, and iron oxides are common in the local soils. Particulate emissions from the foundry will not be acidic or caustic and are not expected to have any effects on soil, vegetation, or crops.

CO has not been found to produce detrimental effects on plants at concentrations below 100 ppm for exposures of one to three weeks. Since the ambient standards have been established at 35 ppm (40 mg/m^3) and 9 ppm (10 mg/m^3) for the 1-hour and 8-hour averages, respectively, there is no threat to plant life from CO emissions at the site.

7.4 Wildlife Impacts

Impacts to wildlife can occur due to direct uptake of pollutants through ingestion or via the skin and more indirectly as a result of air pollution induced changes to wildlife habitat and food source. Impacts of air pollution induced injury and death in wildlife has been focused on pollutants other than CO. It is likely any toxicity most severely in circumstances where air pollutants were likely elevated far above the ambient air quality standards (AAQS), or where significantly elevated concentrations of pollutants occurred on vegetation that is subsequently consumed.

A review of available information indicates there have been no observed adverse impacts to wildlife in the area due to the 1985 and 1992 projects. No pollutants were elevated above the AAQS nor were there elevated concentrations of pollutants that would have affected consumable vegetation.

7.5 Growth Analysis

The elements of the growth analysis include a projection of associated industrial, commercial, and residential growth that will occur in the area due to the proposed project and an estimate of the air emissions generated by such growth.

The FWNA foundry at full build-out will employ approximately two hundred and fifty people. This workforce comes from local communities, and because the foundry will be located approximately fifteen miles from Bowling Green, the remaining workforce will come from within that city area. Therefore, growth impacts are minimal and should not adversely affect the ambient air quality in the surrounding area. The site is bordered by two major roadways (I-65 and State Highway 31), so additional roadways are not planned.

No significant related increases in the residential, commercial, or industrial growth are anticipated in the area because of the construction and operation of the foundry and machining operations.

As no associated industrial or commercial growth is anticipated, no increase in “secondary emissions” or emissions from other facilities in the area are expected from the proposed construction of the new foundry.

7.6 Construction Impacts

The construction of the facility has already occurred. Please review the prior permit application packages if this subject is of interest.

Denotes secondary capture of emissions

Denotes emissions from control device are captured and vented out an alternative control device stack (EU66/EU67/EU84 via ST16; EU35A/EU35B via ST09; EU77/EU78 via ST12)

Denotes emission unit is combined with another existing emission unit with CY2025 air permit application

Denotes emission unit vents to two different air pollution control devices

~~strikethrough~~ Denotes emission unit, air pollution control device and/or stack will not be installed

Denotes secondary capture of emissions

Denotes emissions from control device are captured and vented out an alternative control device stack (EU66/EU67/EU84 via ST16; EU35A/EU35B via ST09; EU77/EU78 via ST12)

Denotes emission unit is combined with another existing emission unit with CY2025 air permit application

Denotes emission unit vents to two different air pollution control devices

~~strikethrough~~ Denotes emission unit, air pollution control device and/or stack will not be installed

Table 3-1. Hourly Emission Calculations

Note 1: PM, PM_{10} and $PM_{2.5}$ emissions are included in the emissions from the air pollution control device vented to the identified stack.

Note 2: Emissions from this air pollution control device are emitted inside the facility and assumed captured via a second air pollution control device associated with the identified stack. "Total Emissions" do not include these units but are assumed to be a portion of the emissions associated with the stack of the secondary air pollution control device.

Note 3: "Total Emissions" do not include the emissions from the emergency generators.

Note 4: Emissions are captured by CU08 and CU11; emissions assigned to CU11 for worksheet construction.

Note 5: Non-PM criteria pollutant emissions are summed to their referenced stack in the table below.

Note 6: The air pollution control device associated with the unit emit indoors and exhaust via the identified stack.

Table 5-1. Project Emissions Increase

Pollutant	PSD SER (tpy)	2025 Permit Revision	
		Emissions Increase (tpy)	PSD Permitting Required? (Yes/No)
Filterable PM	25	28.54	Yes
PM_{10}	15	28.54	Yes
$PM_{2.5}$	10	28.54	Yes
SO_2	40	2.00	No
NO_x	40	15.68	No
VOC	40	223.54	Yes
CO	100	334.44	Yes
Lead	0.6	0.02	No

Note 1: PM, PM_{10} and $PM_{2.5}$ emissions are included in the emissions from the air pollution control device vented to the identified stack.

Note 2: Emissions from this air pollution control device are emitted inside the facility and assumed captured via a second air pollution control device associated with the identified stack. "Total Emissions" do not include these units but are assumed to be a portion of the emissions associated with the stack of the secondary air pollution control device.

Note 3: "Total Emissions" do not include the emissions from the emergency generators.

Note 4: Emissions are captured by CU08 and CU11; emissions assigned to CU11 for worksheet construction.

Note 5: Non-PM criteria pollutant emissions are summed to their referenced stack in the table below.

Note 6: The air pollution control device associated with the unit emit indoors and exhaust via the identified stack.

Table 5-6. BACT Determinations - Particulate Matter

Emission Unit	Description	BACT for PM	BACT for PM_{10}	BACT for $PM_{2.5}$	BACT Justification
EU01	Charge Handling	0.0015 gr/dscf 1.98 lb/hr 8.68 ton/yr	0.0015 gr/dscf 1.98 lb/hr 8.68 ton/yr	0.0015 gr/dscf 1.98 lb/hr 8.68 ton/yr	For this process there is no RBLC determination less than the proposed BACT for an APCD/stack that contains a source of significant condensable PM emissions. One RBLC entry for charge handling operation [RBLC ID MI-429] identified an outlet loading of 0.001 gr/dscf but the units routed to the stack (shotblasting, grinding and waste sand handling) do not have condensable particulates. For this emissions unit Method 5 was used to determine compliance.
EU07	Induction Furnace #1	0.0015 gr/dscf 1.98 lb/hr 8.68 ton/yr	0.0015 gr/dscf 1.98 lb/hr 8.68 ton/yr	0.0015 gr/dscf 1.98 lb/hr 8.68 ton/yr	For this process there is no RBLC determination less than the proposed BACT. For electric induction furnaces, there is one RLBC entry at 0.002 gr/dscf [RBLC ID MI-0429] and one RBLC entry of 0.003 gr/dscf [IN-0147].
EU08	Induction Furnace #2	0.0015 gr/dscf 1.98 lb/hr 8.68 ton/yr	0.0015 gr/dscf 1.98 lb/hr 8.68 ton/yr	0.0015 gr/dscf 1.98 lb/hr 8.68 ton/yr	For this process there is no RBLC determination less than the proposed BACT. For electric induction furnaces, there is one RLBC entry at 0.002 gr/dscf [RBLC ID MI-0429] and one RBLC entry of 0.003 gr/dscf [IN-0147].
EU09	Induction Furnace #3	0.0015 gr/dscf 1.98 lb/hr 8.68 ton/yr	0.0015 gr/dscf 1.98 lb/hr 8.68 ton/yr	0.0015 gr/dscf 1.98 lb/hr 8.68 ton/yr	For this process there is no RBLC determination less than the proposed BACT. For electric induction furnaces, there is one RLBC entry at 0.002 gr/dscf [RBLC ID MI-0429] and one RBLC entry of 0.003 gr/dscf [IN-0147].
EU10	Induction Furnace #4	0.0015 gr/dscf 1.98 lb/hr 8.68 ton/yr	0.0015 gr/dscf 1.98 lb/hr 8.68 ton/yr	0.0015 gr/dscf 1.98 lb/hr 8.68 ton/yr	For this process there is no RBLC determination less than the proposed BACT. For electric induction furnaces, there is one RLBC entry at 0.002 gr/dscf [RBLC ID MI-0429] and one RBLC entry of 0.003 gr/dscf [IN-0147].
EU13	Hot Metal Transfer	0.0015 gr/dscf 1.98 lb/hr 8.68 ton/yr	0.0015 gr/dscf 1.98 lb/hr 8.68 ton/yr	0.0015 gr/dscf 1.98 lb/hr 8.68 ton/yr	For this process there is no RBLC determination less than the proposed BACT. There is one RLBC entry for Hot Metal Transfer at 0.002 gr/dscf [RBLC ID MI-0429].
EU17	Melt and Baghouse Waste Dust Silo	0.003 gr/dscf 0.015 lb/hr 0.068 ton/yr	0.003 gr/dscf 0.015 lb/hr 0.068 ton/yr	0.003 gr/dscf 0.015 lb/hr 0.068 ton/yr	For this process there is no RBLC determination less than the proposed BACT in the equivalent unit of gr/dscf. For silos, there is one additional RLBC entry at 0.003 gr/dscf [RBLC ID IN-0147].
EU19	Mold Silica Sand Silo	0.003 gr/dscf 0.015 lb/hr 0.001 ton/yr	0.003 gr/dscf 0.015 lb/hr 0.001 ton/yr	0.003 gr/dscf 0.015 lb/hr 0.001 ton/yr	For this process there is no RBLC determination less than the proposed BACT in the equivalent unit of gr/dscf. For silos, there is one additional RLBC entry at 0.003 gr/dscf [RBLC ID IN-0147].
EU20	Blend Silo	0.003 gr/dscf 0.015 lb/hr 0.001 ton/yr	0.003 gr/dscf 0.015 lb/hr 0.001 ton/yr	0.003 gr/dscf 0.015 lb/hr 0.001 ton/yr	For this process there is no RBLC determination less than the proposed BACT in the equivalent unit of gr/dscf. For silos, there is one additional RLBC entry at 0.003 gr/dscf [RBLC ID IN-0147].
EU21	Bentonite Silo	0.003 gr/dscf 0.015 lb/hr 0.001 ton/yr	0.003 gr/dscf 0.015 lb/hr 0.001 ton/yr	0.003 gr/dscf 0.015 lb/hr 0.001 ton/yr	For this process, there is no RBLC determination less than the proposed BACT in the equivalent unit of gr/dscf. For silos, there is one additional RLBC entry at 0.003 gr/dscf [RBLC ID IN-0147].
EU22	Mold Sand Handling and Preparation	0.002 gr/dscf 1.75 lb/hr 7.67 ton/yr	0.002 gr/dscf 1.75 lb/hr 7.67 ton/yr	0.002 gr/dscf 1.75 lb/hr 7.67 ton/yr	For this process there is no RBLC determination less than the proposed BACT. There is one RLBC entry for Process ID 81.440 at 0.002 gr/dscf [RBLC ID MI-0429], one RBLC entry at 0.003 gr/dscf [IN-0147] and multiple entries at 0.005 gr/dscf [WI-0236 and WI-0238].
EU33	Mold Making #1	0.0015 gr/dscf 1.43 lb/hr 6.24 ton/yr	0.0015 gr/dscf 1.43 lb/hr 6.24 ton/yr	0.0015 gr/dscf 1.43 lb/hr 6.24 ton/yr	For this process there is no RBLC determination less than the proposed BACT. Table 5-12. BACT Determinations - Carbon Monoxide

Emission Unit	Description	BACT for CO	BACT Justification
EU07	Induction Furnace #1	1.39 lb/ton metal 13.944 lb/hr 13.944 ton/yr	For this process there is no RBLC determination less than the proposed BACT and their was no identification of an emission control device for carbon monoxide. There was one entry at 9.24 lb/hr [MI-0429] and another entry at 44.55 lb/hr [MI-0385]. The MI-0385 entry is for both melting and pouring and cannot be conditioned. It appears the MI-0429 is likely equivalent to 0.33 lb/ton metal but the exhaust gases are mixed with other processes.
EU08	Induction Furnace #2	1.39 lb/ton metal 13.944 lb/hr 13.944 ton/yr	For this process there is no RBLC determination less than the proposed BACT and their was no identification of an emission control device for carbon monoxide. There was one entry at 9.24 lb/hr [MI-0429] and another entry at 44.55 lb/hr [MI-0385]. The MI-0385 entry is for both melting and pouring and cannot be conditioned. It appears the MI-0429 is likely equivalent to 0.33 lb/ton metal but the exhaust gases are mixed with other processes.
EU09	Induction Furnace #3	1.39 lb/ton metal 13.944 lb/hr 13.944 ton/yr	For this process there is no RBLC determination less than the proposed BACT and their was no identification of an emission control device for carbon monoxide. There was one entry at 9.24 lb/hr [MI-0429] and another entry at 44.55 lb/hr [MI-0385]. The MI-0385 entry is for both melting and pouring and cannot be conditioned. It appears the MI-0429 is likely equivalent to 0.33 lb/ton metal but the exhaust gases are mixed with other processes.
EU10	Induction Furnace #4	1.39 lb/ton metal 13.944 lb/hr 13.944 ton/yr	For this process there is no RBLC determination less than the proposed BACT and their was no identification of an emission control device for carbon monoxide. There was one entry at 9.24 lb/hr [MI-0429] and another entry at 44.55 lb/hr [MI-0385]. The MI-0385 entry is for both melting and pouring and cannot be conditioned. It appears the MI-0429 is likely equivalent to 0.33 lb/ton metal but the exhaust gases are mixed with other processes.
EU50	Pouring #1	6.17 lb/ton metal 92.488lb/hr 246.634 ton/yr	For this process there is no RBLC determination less than the proposed BACT and the only control method identified is "mold vent off gas ignition." There are three RBLC entries of 6 lb/ton [WI-0236 (under process 81.44), IN-0147) which appears likely for the addition of pouring, cooling and shakeout (PCS). There are equvalent emission limits of 5 lb/ton metal for several RBLC entries [RBLC ID WI-0238, WI-0256, WI-0288].
EU52	Mold Cooling	See EU50	See EU50
EU53	Shakeout Conveyor	0.515 lb/ton metal 7.725 lb/hr 20.600 ton/yr	For this process there is no RBLC determination less than the proposed BACT and the only control method identified is "mold vent off gas ignition." There are two RBLC entries of 6 lb/ton [WI-0236 (under process 81.44), IN-0147, IN-0188) which appears likely for the addition of pouring, cooling and shakeout (PCS). There are equvalent emission limits of 1 lb/ton metal for several RBLC entries [RBLC ID WI-0238, WI-0239, WI-0256].

Table 5-21. BACT Determinations - Volatile Organic Compounds

Emission Unit	Description	BACT for VOC	BACT Justification
EU07	Induction Furnace #1	0.234 lb/ton metal 2.341 lb/hr 2.341 ton/yr	The RBLC contains no identified of emission control for this process. Two RBLC determinations are less than the proposed BACT. This first emission rate is 0.84 lb/hr [MI-0429]) and another entry has an emission rate exceeding the proposed BACT but is for both melting and pouring operations (5.28 lb/hr [MI-0385]). It appears the MI-0429 is likely equivalent to 0.33 lb/ton metal but the exhaust gases are mixed with other processes.
EU08	Induction Furnace #2	0.234 lb/ton metal 2.341 lb/hr 2.341 ton/yr	The RBLC contains no identified of emission control for this process. Two RBLC determinations are less than the proposed BACT. This first emission rate is 0.84 lb/hr [MI-0429]) and another entry has an emission rate exceeding the proposed BACT but is for both melting and pouring operations (5.28 lb/hr [MI-0385]). It appears the MI-0429 is likely equivalent to 0.33 lb/ton metal but the exhaust gases are mixed with other processes.
EU09	Induction Furnace #3	0.234 lb/ton metal 2.341 lb/hr 2.341 ton/yr	The RBLC contains no identified of emission control for this process. Two RBLC determinations are less than the proposed BACT. This first emission rate is 0.84 lb/hr [MI-0429]) and another entry has an emission rate exceeding the proposed BACT but is for both melting and pouring operations (5.28 lb/hr [MI-0385]). It appears the MI-0429 is likely equivalent to 0.33 lb/ton metal but the exhaust gases are mixed with other processes.
EU10	Induction Furnace #4	0.234 lb/ton metal 2.341 lb/hr 2.341 ton/yr	The RBLC contains no identified of emission control for this process. Two RBLC determinations are less than the proposed BACT. This first emission rate is 0.84 lb/hr [MI-0429]) and another entry has an emission rate exceeding the proposed BACT but is for both melting and pouring operations (5.28 lb/hr [MI-0385]). It appears the MI-0429 is likely equivalent to 0.33 lb/ton metal but the exhaust gases are mixed with other processes.
EU39	PUCB Core Machine #1	4.298 lb/hr 7.862 ton/yr	For this process there is no RBLC determination less than the proposed BACT and no control method identified. Emissions are going to be dependent on binder technology used. It appears only the entries for MI-0429 is using a similar binder technology and has an emission rate of 14.47 lb/hr.
EU40	PUCB Core Machine #2	4.298 lb/hr 7.862 ton/yr	For this process there is no RBLC determination less than the proposed BACT and no control method identified. Emissions are going to be dependent on binder technology used. It appears only the entries for MI-0429 is using a similar binder technology and has an emission rate of 14.47 lb/hr.
EU43	Core Wash Station #1	0.675 lb/hr 0.135 ton/yr	For this process there is no RBLC determination less than the proposed BACT and no control method identified. Emissions are going to be dependent on binder technology used. It appears only the entries for MI-0429 is using a similar binder technology and has an emission rate of 1.43 lb/hr.
EU50	Pouring #1	3.54 lb/ton metal 53.101 lb/hr 141.604 ton/yr	For this process there is no RBLC determination less than the proposed BACT and the only control method identified is "mold vent off gas ignition." There are two RBLC entries of 0.5 lb/ton metal [WI-0238, WI-0256) and 1.8 lb/ton metal which is a chemically bonded mold [IN-0165]. In addition there are two entries for a total emission rate of 1.2 blt/on [IN-0257] and 1.4 lb/ton [IN-0288]. The equivalent emission rate for FWNA is 1.028 lb/ton metal which is less than both of these values.
EU52	Mold Cooling	See EU50 and EU51	See EU50 and EU51
EU53	Shakeout Conveyor	0.616 lb/ton metal 9.240 lb/hr 24.640 ton/yr	For this process there is one RBLC determination less than the proposed BACT and the only control method identified is "mold vent off gas ignition." WI-0238 and WI-0256 have emission rates of 0.1 lb/ton metal. RBLC lists the compliance demonstration as unknown. The facility has been contacted and verified that they cannot meet this emission rate. In addition there are four entries for a total emission rate of 1.2 blt/on [IN-0257], 1.4 lb/ton [IN-0288], 1.4 lb/ton metal [IN-0188] and 1.9 lb/ton metal. The equivalent emission rate for FWNA is 1.028 lb/ton metal which is less than all four of these values.
EU68	Paint Line #3	3.43 lb/hr 13.72 ton/yr	For this process, there were no RBLC determination under either iron and/or steel foundries. For miscellaneous metal parts and products [process id 81.44] only the FWNA was identified. Cost effectiveness analysis supports the identified emission rates as BACT.

EU69	Paint Line #2	3.43 lb/hr 13.72 ton/yr	For this process, there were no RBLC determination under either iron and/or steel foundries. For miscellaneous metal parts and products [process id 81.44] only the FWNA was identified. Cost effectiveness analysis supports the identified emission rates as BACT.
EU71	Paint Line #1	0.992 lb/hr 1.804 ton/yr	For this process, there were no RBLC determination under either iron and/or steel foundries. For miscellaneous metal parts and products [process id 81.44] only the FWNA was identified. Cost effectiveness analysis supports the identified emission rates as BACT.
EU75	Diesel Storage Tank	0.918 lb/hr 0.069 ton/yr	The diesel storage tank shall be equipped with a permanent submerged fill pipe.
EU79	Core Wash Station #2	0.675 lb/hr 0.135 ton/yr	For this process there is no RBLC determination less than the proposed BACT and no control method identified. Emissions are going to be dependent on binder technology used. It appears only the entries for MI-0429 is using a similar binder technology and has an emission rate of 1.43 lb/hr.
EU82	Rust Preventative Application	2.500 lb/hr 1.000 ton/yr	For this process, there were no RBLC determination under either iron and/or steel foundries. For miscellaneous metal parts and products [process id 81.44] only the FWNA was identified. Emission rate could be supported by cost-effectiveness analysis.

Table 6-1. SMC, SIL, NAAQS and Increment Concentrations

Pollutant	Averaging Period	Significant Monitoring Concentration[a,k] (µg/m^3)	Class II SIL[e,g,k] (µg/m^3)	Primary NAAQS (µg/m3)	PSD Class II Increment[f] (µg/m^3)
PM_{10}	24-hour	10	5	150[b]	30[j]
	Annual	NA	1	Revoked[c]	17[k]
$PM_{2.5}$	24-hour	4[d]	1.2	35[h]	9[j]
	Annual	0	0.13	9[i]	4[k]
CO[f]	1-hour	NA	2000	40000[j] (35 ppm)	-
	8-hour	575	500	10000[j] (9 ppm)	-

[a]401 KAR 51:017 Section 7(5)(a) and 40 CFR 52.21(i)(5)(i). See footnote d.

[b]Not to be exceeded more than three times in three consecutive years (H6H for all 5 years modeled together).

[c]Primary and secondary annual PM10 NAAQS of 50 µg/m3 was revoked effective 12/18/2006 [71 FR 6114].

[d]$PM_{2.5}$ SMC determined not authorized by CAA (court decision June 23, 2016), but EPA retains the argument that value can be used as part of an overall monitoring assessment.

[e]401 KAR 51:017 Section 9(2). See footnote g.

[f]401 KAR 51:017 Section 2(1).

[g]USEPA document "Guidance on SIL for Ozone and Fine Particles in PSD Permitting Program" (4/17/2018) identifies annual $PM_{2.5}$ Class II SIL value of 0.2 µg/m^3.

[h]3-year average of the 98th percentile 24-hour average concentration (H8H for each 1-year, 5 separate model runs are averaged together).

[i]3-year average of the annual arithmetic average concetnrations (H1H for each 1-year, 5 spearate model runs are averaged together).

[j]The maximum of the second highest 1-year concentration, 5 separate runs, maximum of the H2H concentrations.

[k]Single highest concentration during the 5-year modeling period.

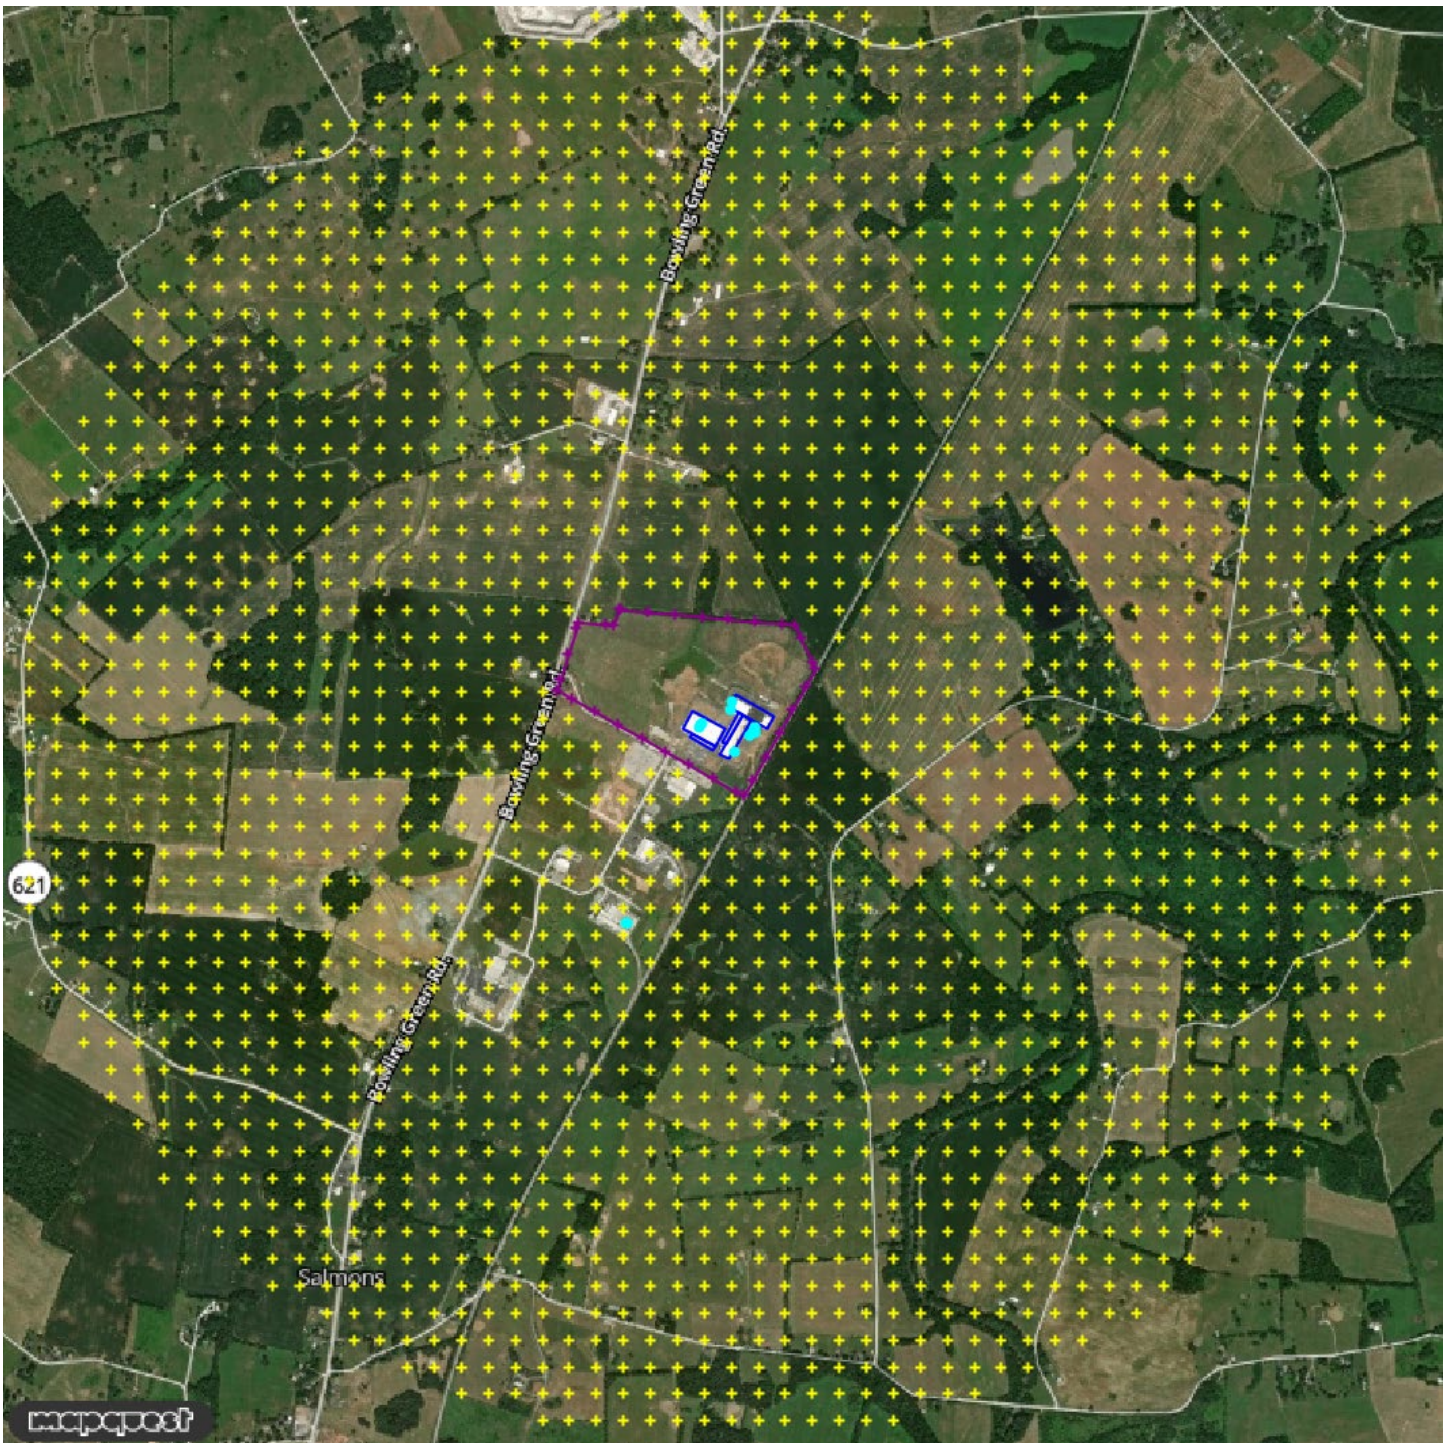

Figure 6-9. Class I Receptor Locations Relative to FWNA

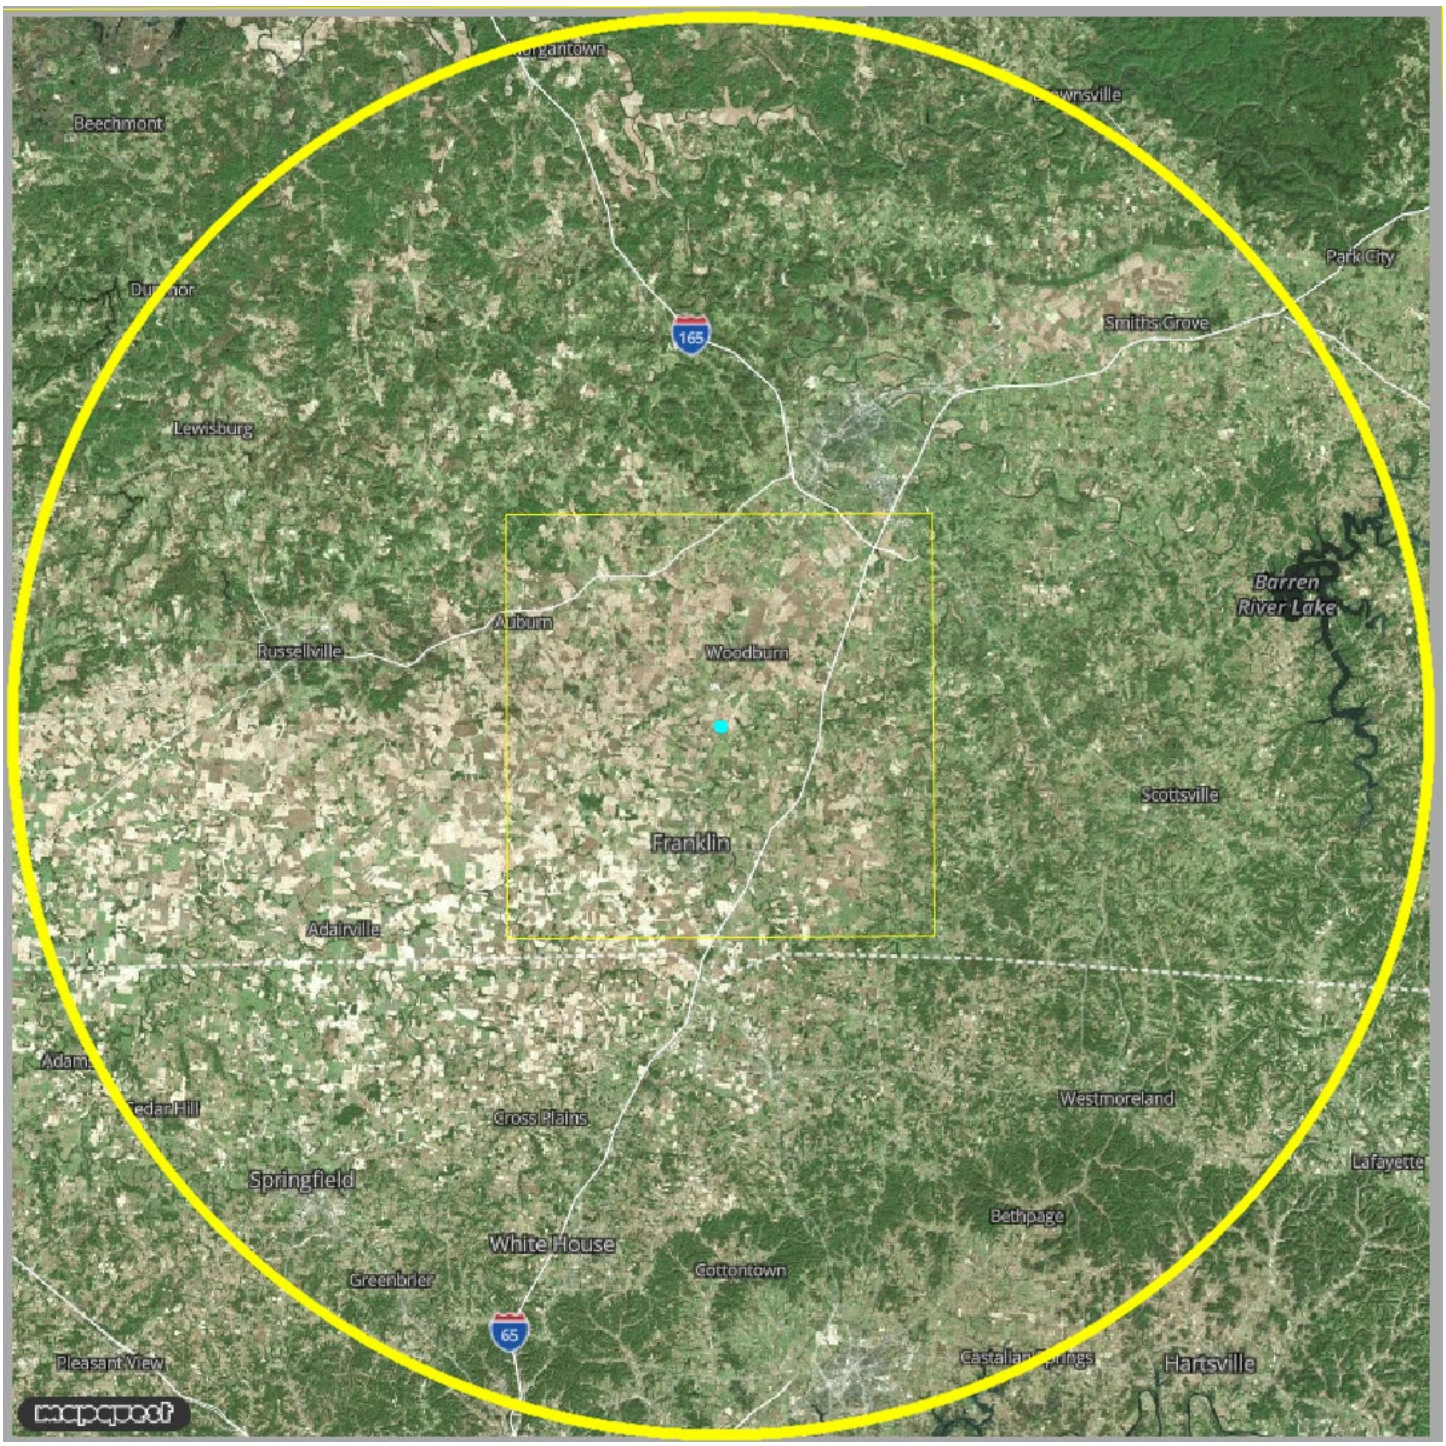

Figure 6-10. Secondary $PM_{2.5}$ Sulfate Ion Impacts from 500 TPY SO_2 Source

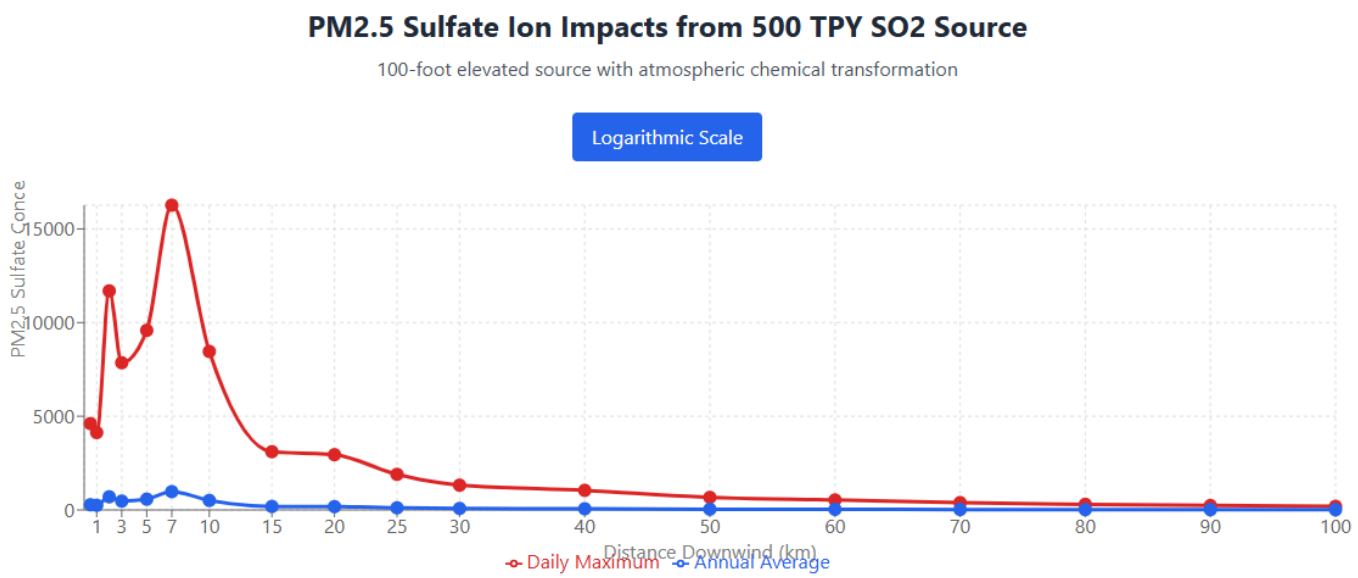

Key Assumptions:

- 500 TPY SO2 = 63.9 g/s emission rate
- 100-foot (30.5 m) elevated point source
- SO2 to SO_4^{2-} conversion increases with distance
- Molecular weight ratio SO4/SO2 = 1.5
- Maximum ground impacts at 3-10 km range

Regulatory Context:

- Class I PSD increment (annual): 0.03 µg/m³
- Class II PSD increment (annual): 0.13 µg/m³
- PM2.5 NAAQS (annual): 9.0 µg/m³
- PM2.5 NAAQS (24-hour): 35 µg/m³

Modeling Approach:

- Accounts for atmospheric dispersion using simplified Gaussian plume principles
- Incorporates SO2 to sulfate chemical transformation that increases with transport time/distance
- Uses molecular weight conversion factor (SO4/SO2 = 1.5)

Key Findings:

- Near-field impacts (0.5-5 km): Lower sulfate formation due to limited conversion time
- Mid-range impacts (10-30 km): Peak sulfate concentrations as conversion efficiency increases
- Far-field impacts (50+ km): Lower concentrations due to dispersion, despite high conversion efficiency

Notes:
1) 2018 test production rate as determined by throughput rate of Pouring Furnace (EU15)
2) CO and VOC test duration was reduced
3) 2018 test was not witnessed by DAQ
4) 2018 test was conducted with emission units that were subsequently routed in 2019 to CU08/ST09

Note 1: PM, PM_{10} and $PM_{2.5}$ emissions are included in the emissions from the air pollution control device vented to the identified stack.

Note 2: Emissions from this air pollution control device are emitted inside the facility and assumed captured via a second air pollution control device associated with the identified stack. "Total Emissions" do not include these units but are assumed to be a portion of the emissions associated with the stack of the secondary air pollution control device.

Note 3: "Total Emissions" do not include the emissions from the emergency generators.

Note 4: Emissions are captured by CU08 and CU11; emissions assigned to CU11 for worksheet construction.

Note 1: PM, PM_{10} and $PM_{2.5}$ emissions are included in the emissions from the air pollution control device vented to the identified stack.

Note 2: Emissions from this air pollution control device are emitted inside the facility and assumed captured via a second air pollution control device associated with the identified stack. "Total Emissions" do not include these units but are assumed to be a portion of the emissions associated with the stack of the secondary air pollution control device.

Note 3: "Total Emissions" do not include the emissions from the emergency generators.

Note 4: Emissions are captured by CU08 and CU11; emissions assigned to CU11 for worksheet construction.

PROPOSED OPERATING SCHEDULE
24 HRS/DAY
8,760 HRS/YEAR

Note 1: Gutow Article, Modern Casting; January 1972; PM emissions from Raw material handling (0.04 lbs/ton) and charge makeup (0.03 lbs/ton) released to the atmosphere. All PM emission were conservatively assumed to be PM-10 emissions.
Note 2: Emission factor based on USEPA PM Calculator (March 2012) PM to $PM_{2.5}$ ratio and uncontrolled PM emission factor.
Note 3: The Alloy Storage emission unit (EU02) is included in this emission unit.
Note 4: Secondary capture of fugitive emissions per testing conducted pursuant to permit term EG01,3.I
Note 5: Hourly capacity based on potential Pouring (EU50) throughput rate
Note 6: Requested maximum tons of gray iron processed per year per rolling 12-month basis

EXAMPLE CALCULATIONS:
Maximum Emission Rate (lb/hr) {building exhausts} = (Emission Factor lb/ton) x (Maximum Hourly Rate tph) x (% returns/100 for PM10 only) x (1- %fugitive rate/100)
Maximum Emission Rate (lb/hr) {fugitive} = (Emission Factor lb/ton) x (Maximum Hourly Rate tph) x (%returns for PM10 only) x (% fugitive emissions rate/100)
Annual (TPY) Emission Rates = (lb/hr emission rate) x (Maximum Annual Melt Rate) / (Maximum Hourly Melt Rate) / (2000 lbs/ton)

POTENTIAL OPERATING SCHEDULE
24 HRS/DAY
8,760 HRS/YEAR

Note 1: AP-42 Fifth Edition, Supplement D, TABLE 1.4-2,-3 and -4.
Note 2: 8.5 MMBtu/hr natural-gas fired burner; 1020 Btu/ft^3 fuel heat content
Note 3: Based on potential operating schedule of 8,760 hours per year
Note 4: Secondary capture of fugitive emissions per testing conducted (EG01,3.I)
Note 5: See air pollution control device worksheet for stack emissions

EXAMPLE CALCULATIONS:
Maximum Emission Rate (lb/hr) {building exhausts} = (Emission Factor lb/ton) x (Maximum Hourly Rate tph) x (% returns/100 for PM10 only) x (1- %fugitive rate/100)
Maximum Emission Rate (lb/hr) {fugitive} = (Emission Factor lb/ton) x (Maximum Hourly Rate tph) x (%returns for PM10 only) x (% fugitive emissions rate/100)
Annual (TPY) Emission Rates = (lb/hr emission rate) x (Maximum Annual Melt Rate) / (Maximum Hourly Melt Rate) / (2000 lbs/ton)

PROPOSED OPERATING SCHEDULE
24 HRS/DAY
8,760 HRS/YEAR

Note 1: Emission factor from FIRE 6.25 SCC 3-04-003-03
Note 2: Emission factor based on USEPA PM Calculator (March 2012) PM to PM2.5 ratio and uncontrolled PM emission factor.
Note 3: Based on upper 95th% Confidence Interval of 2020 and 2024 CU01_ST02 stack test results; considering other units vented to this stack
Note 4: See HAPs calculations provided on air pollution control device worksheet
Note 5: Secondary capture of fugitive emissions per testing conducted (EG01,3.I)
Note 6: Equipment hourly capacity
Note 7: 1/4 of the requested maximum tons of gray iron processed per year per rolling 12-month basis

EXAMPLE CALCULATIONS:
Maximum Stack Emission Rate (lb/hr) {PM & PM-10}=(gr/acfm) x (acfm) x (1 lb / 7000 grains) x (60 min / 1 hr)
Maximum Stack Emission Rate (lb/hr) {Lead}=(gr/acfm) x (acfm) x (1 lb / 7000 grains) x (60 min / 1 hr)*(Lead EF/PM EF)
Maximum Annual (Ton/yr) Stack Emission Rates = (lb/hr emission rate) x (hours of operation per year at max. rate) x (ton/2000 lbs)
Maximum Fugitive Emission Rate (lb/hr) = ((1 - Capture Efficiency/100) x (Emission Factor) x (Melt ton/hr) x (1-(Settling Factor)/100)
Maximum Annual Fugitive Emissions (ton/yr)= (Hourly fugitive emissions (lb/hr)/ hourly Process rate (ton/hr) x (Annual process rate (tons/yr) x (ton/2000 lbs)
Total Emission Rate (lb/hr) = (Maximum Stack Emission Rate lb/hr) + (Maximum Fugitive Emission Rate lb/hr)
Total Emission Rates Annual (TPY)= (annual stack emissions (ton/yr)) + (annual fugitive emissions (ton/yr))

EU17

Maximum Hourly Capacity
0.38 Tons/Hour Note 3

Process Description:
Fritz Winter North America, LP
Melt and Core/Mold Baghouse Dust Silo

Control Device: Melt and Core/Mold BHs Dust Silo Bin Vent Filter (CU02)
SCC Code:
Control Device Outlet: gr/dscf
Airflow: acfm
Stack Gas Temperature: 70 °F

Facility Process Name:		**Criteria Pollutants**								
	Melt and Core/Mold Baghouse Dust Silo									
Emission Factor Basis:		**PM**	**PM10**	**PM2.5**	**SOx**	**NOx**	**VOC**	**CO**	**Lead**	**CO_2e**
Emission Factors:	lb/ton	0.24	0.24	0.24						
(source)		Note 1	Note 2	Note 2						
	Capture Efficiency	100.00	100.00	100.00						
	Control Efficiency									
	Building Capt. Eff									
Maximum Stack Emission Rate:										
	Hourly (lb/hr)	See air pollution control device worksheet for stack emissions								
	Annual (TPY)									
Maximum Fugitive Emission Rate:										
	Hourly (lb/hr)									
	Annual (TPY)									
Total Emission Rate:										
	Hourly (lb/hr)									
	Annual (TPY)									

PROPOSED OPERATING SCHEDULE
24 HRS/DAY
8,760 HRS/YEAR

Note 1: Emission factor from Ohio EPA RACM, Table 2.22-1, pg 2-474, Silo Vent
Note 2: Assumes $PM_{2.5}$ and PM_{10} is equal to PM
Note 3: Hourly capacity based on mass balance of dust from serviced fabric filters
Note 4: Annual based on hourly times 8,760 hours per year

EXAMPLE CALCULATIONS:
Maximum Stack Emission Rate (lb/hr) {PM,PM-10} =(gr/acfm) x (acfm) x (1 lb / 7000 grains) x (60 min / 1 hr)
Maximum Annual (Ton/yr) stack Emission Rates = (lb/hr emission rate) x (hours of operation per year at max. rate) x (ton/2000 lbs)
Maximum Fugitive Emission Rate (lb/hr) = ((1 - Capture Efficiency/100) x (Emission Factor) x (Melt ton/hr) x (1-(Settling Factor)/100)
Maximum Annual Fugitive Emissions (ton/yr)= (Hourly fugitive emissions (lb/hr)/ hourly Process rate (ton/hr) x (Annual process rate (tons/yr) x (ton/2000 lbs)
Total Emission Rate (lb/hr) = (Maximum Stack Emission Rate lb/hr) + (Maximum Fugitive Emission Rate lb/hr)
Total Emission Rates Annual (TPY)= (annual stack emissions (ton/yr)) + (annual fugitive emissions (ton/yr))

PROPOSED OPERATING SCHEDULE
24 HRS/DAY
8,760 HRS/YEAR

Note 1: ASK Chemicals Vendor Test, June 2025, 30 Mins and After (1.02g-0.17g)/36g)=0.0236 g/g binder, for 1.2% Resin Focus 109/209 system
Note 2: Catalyst usage based on 15% of resin; Catalyst 100% emitted; Acid Scrubber amine control efficiency is 97%; (3.33*(1-0.03))/22.22=0.0045 lb/lb resin
Note 3: Emission Factor - 0.236 + 0.0045 = 0.028; Emissions are on a lb/lb resin basis
Note 4: ASK Chemicals Vendor Test based on 1.2% resin (based on sand); identical maximum rate used by FWNA
Note 5: Maximimum catalyst usage is 15% of resin
Note 6: VOC emissions are captured and exhausted to Acid Scrubber (CU07/ST08)
Note 7: Hourly sand processing rate based on equipment capacity
Note 8: Requested rolling 12-month rolling processing rate
Note 9: Ohio RACM Guide, Page 2-219, Table 2.7-1
Note 10: Assumes PM_{10} and $PM_{2.5}$ equivalent to PM

EXAMPLE CALCULATIONS:
Maximum Fugitive Emission Rate (lb/hr) = (Emission Factor) x (process weight rate (ton/hr)) x (1-(Settling Factor)/100)
Annual (TPY) Emission Rates = (lb/hr emission rate) x (1/ Maximum Hourly Process Rate (tons/hr)) x (Annual process weight rate (tons/yr))x (ton/2000)

Emission Factor Basis:		**PM**	**PM10**	**PM2.5**	**SOx**	**NOx**	**VOC**	**CO**	**Lead**	**CO_2e**
Emission Factors:	lb/ton						1700.000			
(source)							Note 1,2			
	Capture Efficiency						100.00			
	Control Efficiency									
	Building Capt. Eff									
Maximum Stack Emission Rate:										
	Hourly (lb/hr)						3.570			
	Annual (TPY)						**6.545**			
Maximum Fugitive Emission Rate:										
	Hourly (lb/hr)									
	Annual (TPY)									
Total Emission Rate:										
	Hourly (lb/hr)						3.570			
	Annual (TPY)						**6.545**			

PROPOSED OPERATING SCHEDULE
24 HRS/DAY
8,760 HRS/YEAR

Note 1: ACMOS 118-63 Core Release (84% VOC by weight per SDS and 1/3/2022 email)
HA NIxStix CB/NB Fast Dry (85% VOC per J. Krause 1/3/2022 email)
Note 2: VOC emissions are captured and exhausted to Acid Scrubber (CU07/ST08)
Note 3: Requested rolling 12-month rolling processing rate

EXAMPLE CALCULATIONS:
Maximum Fugitive Emission Rate (lb/hr) = (Emission Factor) x (process weight rate (ton/hr)) x (1-(Settling Factor)/100)
Annual (TPY) Emission Rates = (lb/hr emission rate) x (1/ Maximum Hourly Process Rate (tons/hr)) x (Annual process weight rate (tons/yr))x (ton/2000)

	Hourly (lb/hr)									
	Annual (TPY)									
Total Emission Rate:										
	Hourly (lb/hr)									
	Annual (TPY)									

PROPOSED OPERATING SCHEDULE
24 HRS/DAY
8,760 HRS/YEAR

Note 1: Emission factor from Bernard S. Gutow article
Note 2: Emission factor from FIRE 6.25 SCC 3-04-003-60
Note 3: Assumes PM2.5 is equal to PM10
Note 4: Secondary capture of fugitive emissions per testing conducted (EG01,3.I)
Note 5: Hourly equipment capacity
Note 6: 1/2 of requested maximum tons of gray iron processed per year per rolling 12-month basis

EXAMPLE CALCULATIONS:
Maximum Stack Emission Rate (lb/hr) {PM,PM-10} =(gr/acfm) x (acfm) x (1 lb / 7000 grains) x (60 min / 1 hr)
Maximum Annual (Ton/yr) stack Emission Rates = (lb/hr emission rate) x (hours of operation per year at max. rate) x (ton/2000 lbs)
Maximum Fugitive Emission Rate (lb/hr) = ((1 - Capture Efficiency/100) x (Emission Factor) x (Melt ton/hr) x (1-(Settling Factor)/100)
Maximum Annual Fugitive Emissions (ton/yr)= (Hourly fugitive emissions (lb/hr)/ hourly Process rate (ton/hr) x (Annual process rate (tons/yr) x (ton/2000 lbs)
Total Emission Rate (lb/hr) = (Maximum Stack Emission Rate lb/hr) + (Maximum Fugitive Emission Rate lb/hr)
Total Emission Rates Annual (TPY)= (annual stack emissions (ton/yr)) + (annual fugitive emissions (ton/yr))

Capture Efficiency							100.00			
Control Efficiency										
Transfer Efficiency										
Maximum Stack Emission Rate:										
Hourly (lb/hr)							1.000			
Annual (TPY)							**4.000**			
Maximum Fugitive Emission Rate:										
Hourly (lb/hr)										
Annual (TPY)										
Total Emission Rate:										
Hourly (lb/hr)							1.000			
Annual (TPY)							**4.000**			

PROPOSED OPERATING SCHEDULE
24 HRS/DAY
8,760 HRS/YEAR

Note 1: Worwag Coatings LLC Reducing Solvent Blend for WG102992 TDS (Thinner Density is 7.26 lb/gal)
Note 2: See air pollution control device worksheet for TAC emissions
Note 3: Hourly equipment capacity
Note 4: Requested maximum material processed per year per rolling 12-month basis

EXAMPLE CALCULATIONS:
Maximum Stack Emission Rate (lb/hr) {PM,PM-10} =(gr/acfm) x (acfm) x (1 lb / 7000 grains) x (60 min / 1 hr)
Maximum Annual (Ton/yr) stack Emission Rates = (lb/hr emission rate) x (hours of operation per year at max. rate) x (ton/2000 lbs)
Maximum Fugitive Emission Rate (lb/hr) = ((1 - Capture Efficiency/100) x (Emission Factor) x (Melt ton/hr) x (1-(Settling Factor)/100)
Maximum Annual Fugitive Emissions (ton/yr)= (Hourly fugitive emissions (lb/hr)/ hourly Process rate (ton/hr) x (Annual process rate (tons/yr) x (ton/2000 lbs)
Total Emission Rate (lb/hr) = (Maximum Stack Emission Rate lb/hr) + (Maximum Fugitive Emission Rate lb/hr)
Total Emission Rates Annual (TPY)= (annual stack emissions (ton/yr)) + (annual fugitive emissions (ton/yr))

PROPOSED OPERATING SCHEDULE
24 HRS/DAY
8,760 HRS/YEAR

Note 1: Geomet 360 SDS (upper end of % solids range)
Note 2: Assumes PM_{10} and $PM_{2.5}$ is equal to PM
Note 3: 95th CI of 2018 and 2024 compliance tests (Geomet 360 Air Quality Data Sheet 1.6 lb/gal VOC at coating density of 11.05 lbs/gal or 0.14 lb/lb coating)
Note 4: Above quantities and emission factors disregard DI water that is used as a thinner
Note 5: See air pollution control device worksheet for TAC emissions
Note 6: Hourly equipment capacity
Note 7: Requested maximum material processed per year per rolling 12-month basis

EXAMPLE CALCULATIONS:
Maximum Stack Emission Rate (lb/hr) {PM,PM-10} =(gr/acfm) x (acfm) x (1 lb / 7000 grains) x (60 min / 1 hr)
Maximum Annual (Ton/yr) stack Emission Rates = (lb/hr emission rate) x (hours of operation per year at max. rate) x (ton/2000 lbs)
Maximum Fugitive Emission Rate (lb/hr) = ((1 - Capture Efficiency/100) x (Emission Factor) x (Melt ton/hr) x (1-(Settling Factor)/100)
Maximum Annual Fugitive Emissions (ton/yr)= (Hourly fugitive emissions (lb/hr)/ hourly Process rate (ton/hr) x (Annual process rate (tons/yr) x (ton/2000 lbs)
Total Emission Rate (lb/hr) = (Maximum Stack Emission Rate lb/hr) + (Maximum Fugitive Emission Rate lb/hr)
Total Emission Rates Annual (TPY)= (annual stack emissions (ton/yr)) + (annual fugitive emissions (ton/yr))

Note 2: Emission rate assumed at upper bound.
Note 3: Maximum hourly 1050 HP; 7,000 Btu/hp-hr (AP-42 Table 3.3-1, footnote e)
Note 4: Maximum Hourly times potential operating hours per year

EXAMPLE CALCULATIONS:
Maximum Emission Rate (lb/hr) {building exhausts} = (Emission Factor lb/ton) x (Maximum Hourly Rate tph) x (% returns/100 for PM10 only) x (1- %fugitive rate/100)
Maximum Emission Rate (lb/hr) {fugitive} = (Emission Factor lb/ton) x (Maximum Hourly Rate tph) x (%returns for PM10 only) x (% fugitive emissions rate/100)
Annual (TPY) Emission Rates = (lb/hr emission rate) x (Maximum Annual Melt Rate) / (Maximum Hourly Melt Rate) / (2000 lbs/ton)

Annual (TPY)	**0.001**	**0.001**	**0.001**						

PROPOSED OPERATING SCHEDULE
1.25 HRS/DAY
Note 3 125 HRS/YEAR

Note 1: Requested BACT PM, PM_{10} and $PM_{2.5}$ emission limit
Note 2: Expected air volume when delivering dust pnuematically from truck to silo.
Note 3: Pnuematic conveying of sand from truck to silo is approximately 1.25 hrs/day, 2 days/week, 50 weeks/yr

EXAMPLE CALCULATIONS:
Maximum Stack Emission Rate (lb/hr) {PM,PM-10} =(gr/acfm) x (acfm) x (1 lb / 7000 grains) x (60 min / 1 hr)
Maximum Annual (Ton/yr) stack Emission Rates = (lb/hr emission rate) x (hours of operation per year at max. rate) x (ton/2000 lbs)
Maximum Fugitive Emission Rate (lb/hr) = ((1 - Capture Efficiency/100) x (Emission Factor) x (Melt ton/hr) x (1-(Settling Factor)/100)
Maximum Annual Fugitive Emissions (ton/yr)= (Hourly fugitive emissions (lb/hr)/ hourly Process rate (ton/hr) x (Annual process rate (tons/yr) x (ton/2000 lbs)
Total Emission Rate (lb/hr) = (Maximum Stack Emission Rate lb/hr) + (Maximum Fugitive Emission Rate lb/hr)
Total Emission Rates Annual (TPY)= (annual stack emissions (ton/yr)) + (annual fugitive emissions (ton/yr))

PROPOSED OPERATING SCHEDULE
24 HRS/DAY
Note 3 8,760 HRS/YEAR

Note 1: Requested BACT PM, PM_{10} and $PM_{2.5}$ emission limit
Note 2: Expected air volume when delivering dust to silo.
Note 3: Assumes delivery of sand is occurring continuously

EXAMPLE CALCULATIONS:
Maximum Stack Emission Rate (lb/hr) {PM,PM-10} =(gr/acfm) x (acfm) x (1 lb / 7000 grains) x (60 min / 1 hr)
Maximum Annual (Ton/yr) stack Emission Rates = (lb/hr emission rate) x (hours of operation per year at max. rate) x (ton/2000 lbs)
Maximum Fugitive Emission Rate (lb/hr) = ((1 - Capture Efficiency/100) x (Emission Factor) x (Melt ton/hr) x (1-(Settling Factor)/100)
Maximum Annual Fugitive Emissions (ton/yr)= (Hourly fugitive emissions (lb/hr)/ hourly Process rate (ton/hr) x (Annual process rate (tons/yr) x (ton/2000 lbs)
Total Emission Rate (lb/hr) = (Maximum Stack Emission Rate lb/hr) + (Maximum Fugitive Emission Rate lb/hr)
Total Emission Rates Annual (TPY)= (annual stack emissions (ton/yr)) + (annual fugitive emissions (ton/yr))

Maximum Fugitive Emission Rate:									
Hourly (lb/hr)									
Annual (TPY)									
Total Emission Rate:									
Hourly (lb/hr)	0.050	0.050	0.050						
Annual (TPY)	**0.221**	**0.221**	**0.221**						

PROPOSED OPERATING SCHEDULE
24 HRS/DAY
8,760 HRS/YEAR

Note 1: Control device emits into plant environment as fugitive emissions.
Note 2: Secondary capture of fugitive emissions per testing conducted (EG01,3.I)
Note 3: Emissions are captured and emitted via Paint Line #1 Booth Filter (CU17) stack (ST15c)

EXAMPLE CALCULATIONS:
Maximum Stack Emission Rate (lb/hr) {PM,PM-10} =(gr/acfm) x (acfm) x (1 lb / 7000 grains) x (60 min / 1 hr)
Maximum Annual (Ton/yr) stack Emission Rates = (lb/hr emission rate) x (hours of operation per year at max. rate) x (ton/2000 lbs)
Maximum Fugitive Emission Rate (lb/hr) = ((1 - Capture Efficiency/100) x (Emission Factor) x (Melt ton/hr) x (1-(Settling Factor)/100)
Maximum Annual Fugitive Emissions (ton/yr)= (Hourly fugitive emissions (lb/hr)/ hourly Process rate (ton/hr) x (Annual process rate (tons/yr) x (ton/2000 lbs)
Total Emission Rate (lb/hr) = (Maximum Stack Emission Rate lb/hr) + (Maximum Fugitive Emission Rate lb/hr)
Total Emission Rates Annual (TPY)= (annual stack emissions (ton/yr)) + (annual fugitive emissions (ton/yr))

PROPOSED OPERATING SCHEDULE
Note 4 1.25 HRS/DAY
Note 4 125 HRS/YEAR

Note 1: Control device emits into plant environment as fugitive emissions.
Note 2: Secondary capture of fugitive emissions per testing conducted (EG01,3.I)
Note 3: Emissions are captured and emitted via Core/Mold Baghouse (CU08) stack (ST09)
Note 4: Pnuematic conveying of sand from truck to silo is approximately 1.25 hrs/day, 2 days/week, 50 weeks/yr

EXAMPLE CALCULATIONS:
Maximum Stack Emission Rate (lb/hr) {PM,PM-10} =(gr/acfm) x (acfm) x (1 lb / 7000 grains) x (60 min / 1 hr)
Maximum Annual (Ton/yr) stack Emission Rates = (lb/hr emission rate) x (hours of operation per year at max. rate) x (ton/2000 lbs)
Maximum Fugitive Emission Rate (lb/hr) = ((1 - Capture Efficiency/100) x (Emission Factor) x (Melt ton/hr) x (1-(Settling Factor)/100)
Maximum Annual Fugitive Emissions (ton/yr)= (Hourly fugitive emissions (lb/hr)/ hourly Process rate (ton/hr) x (Annual process rate (tons/yr) x (ton/2000 lbs)
Total Emission Rate (lb/hr) = (Maximum Stack Emission Rate lb/hr) + (Maximum Fugitive Emission Rate lb/hr)
Total Emission Rates Annual (TPY)= (annual stack emissions (ton/yr)) + (annual fugitive emissions (ton/yr))

PROPOSED OPERATING SCHEDULE
24 HRS/DAY
8,760 HRS/YEAR

Note 1: Gutow Article, Modern Casting; January 1972; PM emissions from Raw material handling (0.04 lbs/ton) and charge makeup (0.03 lbs/ton) released to the atmosphere. All PM emission were conservatively assumed to be PM-10 emissions.
Note 2: Emission factor based on USEPA PM Calculator (March 2012) PM to $PM_{2.5}$ ratio and uncontrolled PM emission factor.
Note 3: The Alloy Storage emission unit (EU02) is included in this emission unit.
Note 5: Hourly capacity based on potential Pouring (EU50) throughput rate
Note 6: Requested maximum tons of gray iron processed per year per rolling 12-month basis

EXAMPLE CALCULATIONS:
Maximum Emission Rate (lb/hr) {building exhausts} = (Emission Factor lb/ton) x (Maximum Hourly Rate tph) x (% returns/100 for PM10 only) x (1- %fugitive rate/100)
Maximum Emission Rate (lb/hr) {fugitive} = (Emission Factor lb/ton) x (Maximum Hourly Rate tph) x (%returns for PM10 only) x (% fugitive emissions rate/100)
Annual (TPY) Emission Rates = (lb/hr emission rate) x (Maximum Annual Melt Rate) / (Maximum Hourly Melt Rate) / (2000 lbs/ton)

POTENTIAL OPERATING SCHEDULE
24 HRS/DAY
8,760 HRS/YEAR

Note 1: AP-42 Fifth Edition, Supplement D, TABLE 1.4-2,-3 and -4.
Note 2: 8.5 MMBtu/hr natural-gas fired burner; 1020 Btu/ft^3 fuel heat content
Note 3: Based on potential operating schedule of 8,760 hours per year

EXAMPLE CALCULATIONS:
Maximum Emission Rate (lb/hr) {building exhausts} = (Emission Factor lb/ton) x (Maximum Hourly Rate tph) x (% returns/100 for PM10 only) x (1- %fugitive rate/100)
Maximum Emission Rate (lb/hr) {fugitive} = (Emission Factor lb/ton) x (Maximum Hourly Rate tph) x (%returns for PM10 only) x (% fugitive emissions rate/100)
Annual (TPY) Emission Rates = (lb/hr emission rate) x (Maximum Annual Melt Rate) / (Maximum Hourly Melt Rate) / (2000 lbs/ton)

PROPOSED OPERATING SCHEDULE
24 HRS/DAY
8,760 HRS/YEAR

Note 1: Hot metal transfer at building monitor. AP-42, Ch. 12-5, Table 12.5-1
Note 2: Emission factor based on USEPA PM Calculator $PM/PM_{10}/PM_{2.5}$ ratio and uncontrolled PM emission factor for SCC 30400320
Note 3: Hourly capacity based on potential Pouring (EU50) throughput rate
Note 4: Requested maximum tons of gray iron processed per year per rolling 12-month basis

EXAMPLE CALCULATIONS:
Maximum Stack Emission Rate (lb/hr) {PM,PM-10} =(gr/acfm) x (acfm) x (1 lb / 7000 grains) x (60 min / 1 hr)
Maximum Annual (Ton/yr) stack Emission Rates = (lb/hr emission rate) x (hours of operation per year at max. rate) x (ton/2000 lbs)
Maximum Fugitive Emission Rate (lb/hr) = ((1 - Capture Efficiency/100) x (Emission Factor) x (Melt ton/hr) x (1-(Settling Factor)/100)
Maximum Annual Fugitive Emissions (ton/yr)= (Hourly fugitive emissions (lb/hr)/ hourly Process rate (ton/hr) x (Annual process rate (tons/yr) x (ton/2000 lbs)
Total Emission Rate (lb/hr) = (Maximum Stack Emission Rate lb/hr) + (Maximum Fugitive Emission Rate lb/hr)
Total Emission Rates Annual (TPY)= (annual stack emissions (ton/yr)) + (annual fugitive emissions (ton/yr))

POTENTIAL OPERATING SCHEDULE
24 HRS/DAY
8,760 HRS/YEAR

Note 1: AP-42 Fifth Edition, Supplement D, TABLE 1.4-2,-3 and -4.
Note 2: 2.0 MMBtu/hr natural-gas fired burner; 1020 Btu/ft^3 fuel heat content
Note 3: Based on potential operating schedule of 8,760 hours per year

EXAMPLE CALCULATIONS:
Maximum Emission Rate (lb/hr) {building exhausts} = (Emission Factor lb/ton) x (Maximum Hourly Rate tph) x (% returns/100 for PM10 only) x (1- %fugitive rate/100)
Maximum Emission Rate (lb/hr) {fugitive} = (Emission Factor lb/ton) x (Maximum Hourly Rate tph) x (%returns for PM10 only) x (% fugitive emissions rate/100)
Annual (TPY) Emission Rates = (lb/hr emission rate) x (Maximum Annual Melt Rate) / (Maximum Hourly Melt Rate) / (2000 lbs/ton)

POTENTIAL OPERATING SCHEDULE
24 HRS/DAY
8,760 HRS/YEAR

Note 1: AP-42 Fifth Edition, Supplement D, TABLE 1.4-2,-3 and -4.
Note 2: 4.0 MMBtu/hr natural-gas fired burner; 1020 But/ft^3 fuel heat content
Note 3: Based on potential operating schedule of 8,760 hours per year

EXAMPLE CALCULATIONS:
Maximum Emission Rate (lb/hr) {building exhausts} = (Emission Factor lb/ton) x (Maximum Hourly Rate tph) x (% returns/100 for PM10 only) x (1- %fugitive rate/100)
Maximum Emission Rate (lb/hr) {fugitive} = (Emission Factor lb/ton) x (Maximum Hourly Rate tph) x (%returns for PM10 only) x (% fugitive emissions rate/100)
Annual (TPY) Emission Rates = (lb/hr emission rate) x (Maximum Annual Melt Rate) / (Maximum Hourly Melt Rate) / (2000 lbs/ton)

PROPOSED OPERATING SCHEDULE
24 HRS/DAY
8,760 HRS/YEAR

Note 1: Stack test at Quality Castings, Orrville, OH.
Note 2: WebFIRE (Aug 20, 2021) SCC 30400320
Note 3: Emission factors taken from the document entitled "Foundry Process Emission Factors: Baseline Emissions from Automotive Foundries in Mexico"; (CERP-Mexico); Table 5.12
Note 4: Based on upper 95th% Confidence Interval of 2019 and 2024 CU08/ST09 stack test results; considering other units vented to this stack
Note 5: Emission factor based on USEPA PM Calculator (March 2012) PM to PM2.5 ratio and uncontrolled PM emission factor.
Note 6: Hourly equipment capacity
Note 7: Requested maximum tons of gray iron processed per year per rolling 12-month basis

EXAMPLE CALCULATIONS:
Maximum Stack Emission Rate (lb/hr) {PM,PM-10} =(gr/acfm) x (acfm) x (1 lb / 7
Maximum Stack Emission Rate (lb/hr) {Lead} =(gr/acfm) x (acfm) x (1 lb / 7000 grains) x (60 min / 1 hr) x (E
Maximum Stack Emissions Rate (lb/hr) {SOx,NOx, VOC, CO} =(Max. Rated Capa
Maximum Annual (Ton/yr) PM, PM10 and lead stack Emission Rates = (lb/hr emission rate) x (hours of ope
Maximum Annual (ton/yr) SOx NOx, VOC and CO stack emissions= (Hourly stack emissions (lb/hr)/ hourly Process rate (ton/hr) x (Annual process rate (tons/yr) x (ton/2000 lbs)
Maximum Fugitive Emission Rate (lb/hr) = ((1 - Capture Efficiency/100) x (Emission Factor) x (Melt ton/hr) x (1-(Settling Factor)/100)
Maximum Annual Fugitive Emissions (ton/yr)= (Hourly fugitive emissions (lb/hr)/ hourly Process rate (ton/hr) x (Annual process rate (tons/yr) x (ton/2000 lbs)
Total Emission Rate (lb/hr) = (Maximum Stack Emission Rate lb/hr) + (Maximum Fugitive Emission Rate lb/hr)
Total Emission Rates Annual (TPY)= (annual stack emissions (ton/yr)) + (annual fugitive emissions (ton/yr))

	Annual (TPY)	**32.000**	**0.090**	**0.090**						

PROPOSED OPERATING SCHEDULE
24 HRS/DAY
8,760 HRS/YEAR

Note 1: Emission factor from Bernard S. Gutow article
Note 2: Emission factor from FIRE 6.25 SCC 3-04-003-60
Note 3: Assumes PM2.5 is equal to PM10
Note 4: Hourly equipment capacity
Note 5: 1/2 of requested maximum tons of gray iron processed per year per rolling 12-month basis

EXAMPLE CALCULATIONS:
Maximum Stack Emission Rate (lb/hr) {PM,PM-10} =(gr/acfm) x (acfm) x (1 lb / 7000 grains) x (60 min / 1 hr)
Maximum Annual (Ton/yr) stack Emission Rates = (lb/hr emission rate) x (hours of operation per year at max. rate) x (ton/2000 lbs)
Maximum Fugitive Emission Rate (lb/hr) = ((1 - Capture Efficiency/100) x (Emission Factor) x (Melt ton/hr) x (1-(Settling Factor)/100)
Maximum Annual Fugitive Emissions (ton/yr)= (Hourly fugitive emissions (lb/hr)/ hourly Process rate (ton/hr) x (Annual process rate (tons/yr) x (ton/2000 lbs)
Total Emission Rate (lb/hr) = (Maximum Stack Emission Rate lb/hr) + (Maximum Fugitive Emission Rate lb/hr)
Total Emission Rates Annual (TPY)= (annual stack emissions (ton/yr)) + (annual fugitive emissions (ton/yr))

Annual (TPY)		**1.230**	**1.230**	**1.230**			**1.804**			

PROPOSED OPERATING SCHEDULE
24 HRS/DAY
8,760 HRS/YEAR

Note 1: Geomet 360 SDS (upper end of % solids range)
Note 2: Assumes PM_{10} and $PM_{2.5}$ is equal to PM
Note 3: Geomet 360 Air Quality Data Sheet (1.6 lb/gal VOC at coating density of 11.05 lbs/gal
Note 4: Above quantities and emission factors disregard DI water that is used as a thinner
Note 5: Hourly equipment capacity
Note 6: Requested maximum material processed per year per rolling 12-month basis

EXAMPLE CALCULATIONS:
Maximum Stack Emission Rate (lb/hr) {PM,PM-10} =(gr/acfm) x (acfm) x (1 lb / 7000 grains) x (60 min / 1 hr)
Maximum Annual (Ton/yr) stack Emission Rates = (lb/hr emission rate) x (hours of operation per year at max. rate) x (ton/2000 lbs)
Maximum Fugitive Emission Rate (lb/hr) = ((1 - Capture Efficiency/100) x (Emission Factor) x (Melt ton/hr) x (1-(Settling Factor)/100)
Maximum Annual Fugitive Emissions (ton/yr)= (Hourly fugitive emissions (lb/hr)/ hourly Process rate (ton/hr) x (Annual process rate (tons/yr) x (ton/2000 lbs)
Total Emission Rate (lb/hr) = (Maximum Stack Emission Rate lb/hr) + (Maximum Fugitive Emission Rate lb/hr)
Total Emission Rates Annual (TPY)= (annual stack emissions (ton/yr)) + (annual fugitive emissions (ton/yr))
